Chapter 6. Deprecated List..... 193

Chapter 1. Release Notes

1.1. 7.0 Release

Stability improvements. No API additions or changes.

1.2. 6.5 Release

Predicate registers

The per-thread predicate registers can be accessed and modified via the `readPredicates()` and `writePredicates()` calls. Each of these calls expects a buffer of sufficient size to cover all predicates for the current GPU architecture. The number of current predicate registers can be read back via the `getNumPredicates()` API call.

Condition code register

The per-thread condition code register can be accessed and modified via the `readCCRegister()` and `writeCCRegister()` calls. The condition code register is a unsigned 32-bit register, whose format may vary by GPU architecture.

Device Name

The `getDeviceName()` API returns a string containing the publically exposed product name of the GPU.

API Error Reporting Improvement

The symbol `CUDBG_REPORT_DRIVER_API_ERROR_FLAGS` points to an unsigned 32-bit integer in the application's process space that controls API error reporting. The values that can be written into this flag are specified in the `CUDBGReportDriverApiErrorFlags` enum. In 6.5, setting the bit corresponding to `CUDBG_REPORT_DRIVER_API_ERROR_FLAGS_SUPPRESS_NOT_READY` in the variable `CUDBG_REPORT_DRIVER_API_ERROR_FLAGS` is supported. This will prevent CUDA API calls that return the runtime API error code `cudaErrorNotReady` or the driver API error code `cuErrorNotReady` from executing the CUDA API error reporting function.

Chapter 2. Introduction

This document describes the API for the set routines and data structures available in the CUDA library to any debugger.

Starting with 3.0, the CUDA debugger API includes several major changes, of which only few are directly visible to end-users:

- ▶ Performance is greatly improved, both with respect to interactions with the debugger and the performance of applications being debugged.
- ▶ The format of cubins has changed to ELF and, as a consequence, most restrictions on debug compilations have been lifted. More information about the new object format is included below.

The debugger API has significantly changed, reflected in the CUDA-GDB sources.

2.1. Debugger API

The CUDA Debugger API was developed with the goal of adhering to the following principles:

- ▶ Policy free
- ▶ Explicit
- ▶ Axiomatic
- ▶ Extensible
- ▶ Machine oriented

Being explicit is another way of saying that we minimize the assumptions we make. As much as possible the API reflects machine state, not internal state.

There are two major "modes" of the devices: stopped or running. We switch between these modes explicitly with `suspendDevice` and `resumeDevice`, though the machine may suspend on its own accord, for example when hitting a breakpoint.

Only when stopped, can we query the machine's state. Warp state includes which function is it running, which block, which lanes are valid, etc.

As of CUDA 6.0, state collection functions in the debug API will return `CUDBG_ERROR_RUNNING_DEVICE` if called without first calling the `suspendDevice` entry point to ensure the device is stopped.

Clients of the debug API should suspend all devices before servicing a `CUDBGEvent`. A valid `CUDBGEvent` is only guaranteed to be returned after the notification callback set using `CUDBGAPI_st::setNotifyNewEventCallback()` is executed. Any debug API entry point will return `CUDBG_ERROR_RECURSIVE_API_CALL` when the call is made from within the notification callback set using `CUDBGAPI_st::setNotifyNewEventCallback()`.

2.2. ELF and DWARF

CUDA applications are compiled in ELF binary format.

Starting with CUDA 6.0, DWARF device information is obtained through an API call of `CUDBGAPI_st::getElfImageByHandle` using the handle exposed from `CUDBGEvent` of type `CUDBG_EVENT_ELF_IMAGE_LOADED`. This means that the information is not available until runtime, after the CUDA driver has loaded. The DWARF device information lifetime is valid until it is unloaded, which presents a `CUDBGEvent` of type `CUDBG_EVENT_ELF_IMAGE_UNLOADED`.

In CUDA 5.5 and earlier, the DWARF device information was returned as part of the `CUDBGEvent` of type `CUDBG_EVENT_ELF_IMAGE_LOADED`. The pointers presented in `CUDBGEvent55` were read-only pointers to memory managed by the debug API. The memory pointed to was implicitly scoped to the lifetime of the loading CUDA context. Accessing the returned pointers after the context was destroyed resulted in undefined behavior.

DWARF device information contains physical addresses for all device memory regions except for code memory. The address class field (`DW_AT_address_class`) is set for all device variables, and is used to indicate the memory segment type (`ptxStorageKind`). The physical addresses must be accessed using several segment-specific API calls.

For memory reads, see:

- ▶ `CUDBGAPI_st::readCodeMemory()`
- ▶ `CUDBGAPI_st::readConstMemory()`
- ▶ `CUDBGAPI_st::readGlobalMemory()`
- ▶ `CUDBGAPI_st::readParamMemory()`
- ▶ `CUDBGAPI_st::readSharedMemory()`
- ▶ `CUDBGAPI_st::readLocalMemory()`
- ▶ `CUDBGAPI_st::readTextureMemory()`

For memory writes, see:

- ▶ `CUDBGAPI_st::writeGlobalMemory()`
- ▶ `CUDBGAPI_st::writeParamMemory()`

- ▶ CUDBGAPI_st::writeSharedMemory()
- ▶ CUDBGAPI_st::writeLocalMemory()

Access to code memory requires a virtual address. This virtual address is embedded for all device code sections in the device ELF image. See the API call:

- ▶ CUDBGAPI_st::readVirtualPC()

Here is a typical DWARF entry for a device variable located in memory:

```
<2><321>: Abbrev Number: 18 (DW_TAG_formal_parameter)
  DW_AT_decl_file   : 27
  DW_AT_decl_line   : 5
  DW_AT_name        : res
  DW_AT_type        : <2c6>
  DW_AT_location    : 9 byte block: 3 18 0 0 0 0 0 0 0      (DW_OP_addr: 18)
  DW_AT_address_class: 7
```

The above shows that variable 'res' has an address class of 7 (ptxParamStorage). Its location information shows it is located at address 18 within the parameter memory segment.

Local variables are no longer spilled to local memory by default. The DWARF now contains variable-to-register mapping and liveness information for all variables. It can be the case that variables are spilled to local memory, and this is all contained in the DWARF information which is ULEB128 encoded (as a DW_OP_regx stack operation in the DW_AT_location attribute).

Here is a typical DWARF entry for a variable located in a local register:

```
<3><359>: Abbrev Number: 20 (DW_TAG_variable)
  DW_AT_decl_file   : 27
  DW_AT_decl_line   : 7
  DW_AT_name        : c
  DW_AT_type        : <1aa>
  DW_AT_location    : 7 byte block: 90 b9 e2 90 b3 d6 4      (DW_OP_regx:
160631632185)
  DW_AT_address_class: 2
```

This shows variable 'c' has address class 2 (ptxRegStorage) and its location can be found by decoding the ULEB128 value, DW_OP_regx: 160631632185. See cuda-tdep.c in the cuda-gdb source drop for information on decoding this value and how to obtain which physical register holds this variable during a specific device PC range.

Access to physical registers liveness information requires a 0-based physical PC. See the API call:

- ▶ CUDBGAPI_st::readPC()

2.3. ABI Support

ABI support is handled through the following thread API calls:

- ▶ CUDBGAPI_st::readCallDepth()
- ▶ CUDBGAPI_st::readReturnAddress()

► `CUDBGAPI_st::readVirtualReturnAddress()`

The return address is not accessible on the local stack and the API call must be used to access its value.

For more information, please refer to the ABI documentation titled "Fermi ABI: Application Binary Interface".

2.4. Exception Reporting

Some kernel exceptions are reported as device events and accessible via the API call:

► `CUDBGAPI_st::readLaneException()`

The reported exceptions are listed in the `CUDBGException_t` enum type. Each prefix, (Device, Warp, Lane), refers to the precision of the exception. That is, the lowest known execution unit that is responsible for the origin of the exception. All lane errors are precise; the exact instruction and lane that caused the error are known. Warp errors are typically within a few instructions of where the actual error occurred, but the exact lane within the warp is not known. On device errors, we *may* know the *kernel* that caused it. Explanations about each exception type can be found in the documentation of the struct.

Exception reporting is only supported on Fermi (sm_20 or greater).

2.5. Attaching and Detaching

The debug client must take the following steps to attach to a running CUDA application:

1. Attach to the CPU process corresponding to the CUDA application. The CPU part of the application will be frozen at this point.
2. Check to see if the `CUDBG_IPC_FLAG_NAME` variable is accessible from the memory space of the application. If not, it implies that the application has not loaded the CUDA driver, and the attaching to the application is complete.
3. Make a dynamic (inferior) function call to the function `cudbgApilnit()` with an argument of "2", i.e., "`cudbgApilnit(2)`", e.g. by using `ptrace(2)` on Linux. This causes a helper process to be forked off from the application, which assists in attaching to the CUDA process.
4. Ensure that the initialization of the CUDA debug API is complete, or wait till API initialization is successful (i.e. call the "`initialize()`" API method until it succeeds).
5. Make the "`initializeAttachStub()`" API call to initialize the helper process that was forked off from the application earlier.
6. Read the value of the `CUDBG_RESUME_FOR_ATTACH_DETACH` variable from the memory space of the application:
 - If the value is non-zero, resume the CUDA application so that more data can be collected about the application and sent to the debugger. When the application is

resumed, the debug client can expect to receive various CUDA events from the CUDA application. Once all state has been collected, the debug client will receive the event `CUDBG_EVENT_ATTACH_COMPLETE`.

- ▶ If the value is zero, there is no more attach data to collect. Set the `CUDBG_IPC_FLAG_NAME` variable to 1 in the application's process space, which enables further events from the CUDA application.
7. At this point, attaching to the CUDA application is complete and all GPUs belonging to the CUDA application will be suspended.

The debug client must take the following steps to detach from a running CUDA application:

1. Check to see if the `CUDBG_IPC_FLAG_NAME` variable is accessible from the memory space of the application, and that the CUDA debug API is initialized. If either of these conditions is not met, treat the application as CPU-only and detach from the application.
2. Next, make the "clearAttachState" API call to prepare the CUDA debug API for detach.
3. Make a dynamic (inferior) function call to the function `cudbgApiDetach()` in the memory space of the application, e.g. by using `ptrace(2)` on Linux. This causes CUDA driver to setup state for detach.
4. Read the value of the `CUDBG_RESUME_FOR_ATTACH_DETACH` variable from the memory space of the application. If the value is non-zero, make the "requestCleanupOnDetach" API call.
5. Set the `CUDBG_DEBUGGER_INITIALIZED` variable to 0 in the memory space of the application. This makes sure the debugger is reinitialized from scratch if the debug client re-attaches to the application in the future.
6. If the value of the `CUDBG_RESUME_FOR_ATTACH_DETACH` variable was found to be non-zero in step 4, delete all breakpoints and resume the CUDA application. This allows the CUDA driver to perform cleanups before the debug client detaches from it. Once the cleanup is complete, the debug client will receive the event `CUDBG_EVENT_DETACH_COMPLETE`.
7. Set the `CUDBG_IPC_FLAG_NAME` variable to zero in the memory space of the application. This prevents any more callbacks from the CUDA application to the debugger.
8. The client must then finalize the CUDA debug API.
9. Finally, detach from the CPU part of the CUDA application. At this point all GPUs belonging to the CUDA application will be resumed.

CUDBGResult (*CUDBGAPI_st::resumeWarpsUntilPC) (uint32_t devId, uint32_t sm, uint64_t warpMask, uint64_t virtPC)

Inserts a temporary breakpoint at the specified virtual PC, and resumes all warps in the specified bitmask on a given SM. As compared to `CUDBGAPI_st::resumeDevice`, `CUDBGAPI_st::resumeWarpsUntilPC` provides finer-grain control by resuming a selected set of warps on the same SM. The main intended usage is to accelerate the single-stepping process when the target PC is known in advance. Instead of single-stepping each warp individually until the target PC is hit, the client can issue this API. When this API is used, errors within CUDA kernels will no longer be reported precisely. In the situation where resuming warps is not possible, this API will return `CUDBG_ERROR_WARP_RESUME_NOT_POSSIBLE`. The client should then fall back to using `CUDBGAPI_st::singleStepWarp` or `CUDBGAPI_st::resumeDevice`.

Parameters

devId

- device index

sm

- the SM index

warpMask

- the bitmask of warps to resume (1 = resume, 0 = do not resume)

virtPC

- the virtual PC where the temporary breakpoint will be inserted

3.10. Events

One of those events will create a [CUDBGEvent](#):

- ▶ the elf image of the current kernel has been loaded and the addresses within its DWARF sections have been relocated (and can now be used to set breakpoints),
- ▶ a device breakpoint has been hit,
- ▶ a CUDA kernel is ready to be launched,
- ▶ a CUDA kernel has terminated.

When a [CUDBGEvent](#) is created, the debugger is notified by calling the callback functions registered with `setNotifyNewEventCallback()` after the API struct initialization. It is up to the debugger to decide what method is best to be notified. The debugger API routines cannot be called from within the callback function or the routine will return an error.

Upon notification the debugger is responsible for handling the [CUDBGEvents](#) in the event queue by using [CUDBGAPI_st::getNextEvent\(\)](#), and for acknowledging the debugger API that the event has been handled by calling `CUDBGAPI_st::acknowledgeEvent()`. In the case of an event raised by the device itself, such as a breakpoint being hit, the event queue will be empty. It is the responsibility of the debugger to inspect the hardware any time a [CUDBGEvent](#) is received.

Example:

```

^CUDBGEvent event;
  CUDBGResult res;
  for (res = cudbgAPI->getNextEvent(&event);
       res == CUDBG_SUCCESS && event.kind != CUDBG_EVENT_INVALID;
       res = cudbgAPI->getNextEvent(&event)) {
    switch (event.kind)
    {
      case CUDBG_EVENT_ELF_IMAGE_LOADED:
        //...
        break;
      case CUDBG_EVENT_KERNEL_READY:
        //...
        break;
      case CUDBG_EVENT_KERNEL_FINISHED:
        //...
        break;
      default:
        error(...);
    }
  }

```

See `cuda-tdep.c` and `cuda-linux-nat.c` files in the `cuda-gdb` source code for a more detailed example on how to use `CUDBGEvent`.

CUDBGResult (*resumeWarpsUntilPC) (uint32_t devId, uint32_t sm, uint64_t warpMask, uint64_t virtPC)

Inserts a temporary breakpoint at the specified virtual PC, and resumes all warps in the specified bitmask on a given SM. As compared to `CUDBGAPI_st::resumeDevice`, `CUDBGAPI_st::resumeWarpsUntilPC` provides finer-grain control by resuming a selected set of warps on the same SM. The main intended usage is to accelerate the single-stepping process when the target PC is known in advance. Instead of single-stepping each warp individually until the target PC is hit, the client can issue this API. When this API is used, errors within CUDA kernels will no longer be reported precisely. In the situation where resuming warps is not possible, this API will return

CUDBG_ERROR_WARP_RESUME_NOT_POSSIBLE. The client should then fall back to using CUDBGAPI_st::singleStepWarp or CUDBGAPI_st::resumeDevice.

Parameters

- device index

sm

- the SM index

warpMask

- the bitmask of warps to resume (1 = resume, 0 = do not resume)

- the virtual PC where the temporary breakpoint will be inserted
