## 1.10.8. Resize

Resize functions use scale factor automatically determined by the width and height ratios of input and output *Region-Of-Interest (ROI)*.

This simplified function replaces the previous version which was deprecated in an earlier release. In this function the resize scale factor is automatically determined by the width and height ratios of oSrcRectROI and oDstRectROI. If either of those parameters intersect their respective image sizes then pixels outside the image size width and height will not be processed.

Resize supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

The resize primitives return the following error codes: *Resize Error Codes*.

### GetResizeTiledSourceOffset

Helper function that can be used when tiling a destination image with a source image using multiple Resize calls.

oSrcRectROI and oDstRectROI widths and heights should remain unmodified even if they will overlap source and destination image sizes. oDstRectROI offsets should be set to the destination offset of the new tile. Resize function processing will stop when source or destination image sizes are reached, any unavailable source image pixels beyond source image size will be border replicated. There is no particular association assumed between source and destination image locations. The values of oSrcRectROI.x and oSrcRectROI.y are ignored during this function call.

*NppStatus* **nppiGetResizeTiledSourceOffset**(*NppiRect* oSrcRectROI, *NppiRect* oDstRectROI, *NppiPoint* \*pNewSrcRectOffset)

**Parameters**

- ▶ **oSrcRectROI** – Region of interest in the source image (may overlap source image size width and height).
- ▶ **oDstRectROI** – Region of interest in the destination image (may overlap destination image size width and height).
- ▶ **pNewSrcRectOffset** – Pointer to host memory *NppiPoint* object that will contain the new source image ROI offset to be used in the *nppiResize* call to generate that tile.

**Returns** *Image Data Related Error Codes, ROI Related Error Codes, Resize Error Codes*

**Resize**

Resizes images.

## Diagram of batch resize functions for variable ROIs

## 1.10.11. ResizeBatch

Above is the diagram of batch resize functions for variable ROIs. Figure shows the flexibility that the API can handle. The ROIs for source and destination images can be any rectangular width and height that reflects the needed resize factors, inside or beyond the image boundary.

ResizeBatch functions use scale factor automatically determined by the width and height ratios for each pair of input / output images in provided batches.

In this function as in `nppiResize` the resize scale factor is automatically determined by the width and height ratios of `oSrcRectROI` and `oDstRectROI`. If either of those parameters intersect their respective image sizes then pixels outside the image size width and height will not be processed. Details of the resize operation are described above in the `Resize` section. `ResizeBatch` generally takes the same parameter list as `Resize` except that there is a list of `N` instances of those parameters ( $N > 1$ ) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of `oSrcRectROI` and `oDstRectROI` values are applied to each source image and destination image in the batch in the `nppiResizeBatch` version of the function while per image specific `oSrcRectROI` and `oDstRectROI` values can be used in the `nppiResizeBatch_Advanced` version of the function. Source and destination image sizes may vary but `oSmallestSrcSize` and `oSmallestDstSize` must be set to the smallest source and destination image sizes in the batch. The parameters in the `NppiResizeBatchCXR` structure represent the corresponding per-image `nppiResize` parameters for each image in the `nppiResizeBatch` functions and the `NppImageDescriptor` and `NppiResizeBatchROI_Advanced` structures represent the corresponding per-image `nppiResize` parameters for the `nppiResizeBatch_Advanced` functions. The `NppiResizeBatchCXR` or `NppImageDescriptor` and `NppiResizeBatchROI_Advanced` arrays must be in device memory.

ResizeBatch supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_SUPER
```

The resize primitives return the following error codes: *Resize Error Codes*.

## 1.10.12. Remap

Routines providing remap functionality.

Remap supports the following interpolation modes:

NPPI\_INTER\_NN    NPPI\_INTER\_LINEAR    NPPI\_INTER\_CUBIC    NPPI\_INTER\_CUBIC2P\_BSPLINE  
 NPPI\_INTER\_CUBIC2P\_CATMULLROM NPPI\_INTER\_CUBIC2P\_BO5C03 NPPI\_INTER\_LANCZOS

Remap chooses source pixels using pixel coordinates explicitly supplied in two 2D device memory image arrays pointed to by the *pXMap* and *pYMap* pointers. The *pXMap* array contains the X coordinate and the *pYMap* array contains the Y coordinate of the corresponding source image pixel to use as input. These coordinates are in floating point format so fraction pixel positions can be used. The coordinates of the source pixel to sample are determined as follows:

$nSrcX = pXMap[nDstX, nDstY]$   $nSrcY = pYMap[nDstX, nDstY]$

In the Remap functions below source image clip checking is handled as follows:

If the source pixel fractional *x* and *y* coordinates are greater than or equal to *oSizeROI.x* and less than *oSizeROI.x + oSizeROI.width* and greater than or equal to *oSizeROI.y* and less than *oSizeROI.y + oSizeROI.height* then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

## 1.10.13. Error Codes

The remap primitives return the following error codes:

- `NPP_WRONG_INTERSECTION_ROI_ERROR` indicates an error condition if `srcROIrect` has no intersection with the source image.
- `NPP_INTERPOLATION_ERROR` if `eInterpolation` has an illegal value.

## 1.10.14. Rotate

Rotates an image around the origin (0,0) and then shifts it.

### 1.10.14.1 Rotate Error Codes

- ▶ **NPP\_INTERPOLATION\_ERROR** if eInterpolation has an illegal value.
- ▶ **NPP\_RECTANGLE\_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1.
- ▶ **NPP\_WRONG\_INTERSECTION\_ROI\_ERROR** indicates an error condition if srcROIrect has no intersection with the source image.
- ▶ **NPP\_WRONG\_INTERSECTION\_QUAD\_WARNING** indicates a warning that no operation is performed if the transformed source ROI does not intersect the destination ROI.

## 1.10.15. Rotate Utility Functions

The set of rotate utility functions.

## Functions

*NppStatus* **nppiGetRotateQuad**(*NppiRect* oSrcROI, double aQuad[4][2], double nAngle, double nShiftX, double nShiftY)

Compute shape of rotated image.

### Parameters

- ▶ **oSrcROI** – Region-of-interest of the source image.
- ▶ **aQuad** – Array of 2D points. These points are the locations of the corners of the rotated ROI.
- ▶ **nAngle** – The rotation nAngle.
- ▶ **nShiftX** – Post-rotation shift in x-direction
- ▶ **nShiftY** – Post-rotation shift in y-direction

**Returns** *ROI Related Error Codes.*

*NppStatus* **nppiGetRotateBound**(*NppiRect* oSrcROI, double aBoundingBox[2][2], double nAngle, double nShiftX, double nShiftY)

Compute bounding-box of rotated image.

### Parameters

- ▶ **oSrcROI** – Region-of-interest of the source image.
- ▶ **aBoundingBox** – Two 2D points representing the bounding-box of the rotated image. All four points from `nppiGetRotateQuad` are contained inside the axis-aligned rectangle spanned by the the two points of this bounding box.
- ▶ **nAngle** – The rotation angle.
- ▶ **nShiftX** – Post-rotation shift in x-direction.
- ▶ **nShiftY** – Post-rotation shift in y-direction.

**Returns** *ROI Related Error Codes.*

## 1.10.16. Mirror

Mirrors images horizontally, vertically or diagonally.

### 1.10.16.1 Mirror Error Codes

- ▶ `NPP_MIRROR_FLIP_ERROR` if flip has an illegal value.
- ▶ `NPP_SIZE_ERROR` if in\_place ROI width or height are not even numbers.

### 1.10.16.2 Common parameters for nppiMirror functions:

### 1.10.17.2 Affine Transform Utility Functions

The set of affine transform utility functions.

#### Functions

*NppStatus* **nppiGetAffineTransform**(*NppiRect* oSrcROI, const double aQuad[4][2], double aCoeffs[2][3])

Computes affine transform coefficients based on source ROI and destination quadrilateral.

The function computes the coefficients of an affine transformation that maps the given source ROI (axis aligned rectangle with integer coordinates) to a quadrilateral in the destination image.

An affine transform in 2D is fully determined by the mapping of just three vertices. This function's API allows for passing a complete quadrilateral effectively making the problem overdetermined. What this means in practice is, that for certain quadrilaterals it is not possible to find an affine transform that would map all four corners of the source ROI to the four vertices of that quadrilateral.

The function circumvents this problem by only looking at the first three vertices of the destination image quadrilateral to determine the affine transformation's coefficients. If the destination quadrilateral is indeed one that cannot be mapped using an affine transformation the function informs the user of this situation by returning a `NPP_AFFINE_QUAD_INCORRECT_WARNING`.

#### Parameters

- ▶ **oSrcROI** – The source ROI. This rectangle needs to be at least one pixel wide and high. If either width or height are less than one an `NPP_RECTANGLE_ERROR` is returned.
- ▶ **aQuad** – The destination quadrilateral.
- ▶ **aCoeffs** – The resulting affine transform coefficients.

#### Returns

- Error codes:
- ▶ `NPP_SIZE_ERROR` Indicates an error condition if any image dimension has zero or negative value
  - ▶ `NPP_RECTANGLE_ERROR` Indicates an error condition if width or height of the intersection of the `oSrcROI` and source image is less than or equal to 1
  - ▶ `NPP_COEFFICIENT_ERROR` Indicates an error condition if coefficient values are invalid
  - ▶ `NPP_AFFINE_QUAD_INCORRECT_WARNING` Indicates a warning when quad does not conform to the transform properties. Fourth vertex is ignored, internally computed coordinates are used instead

*NppStatus* **nppiGetAffineQuad**(*NppiRect* oSrcROI, double aQuad[4][2], const double aCoeffs[2][3])

Compute shape of transformed image.

This method computes the quadrilateral in the destination image that the source ROI is transformed into by the affine transformation expressed by the coefficients array (`aCoeffs`).

#### Parameters

- ▶ **oSrcROI** – The source ROI.
- ▶ **aQuad** – The resulting destination quadrangle.

- ▶ **aCoeffs** – The affine transform coefficients.

**Returns** Error codes:

- ▶ **NPP\_SIZE\_ERROR** Indicates an error condition if any image dimension has zero or negative value
- ▶ **NPP\_RECTANGLE\_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ **NPP\_COEFFICIENT\_ERROR** Indicates an error condition if coefficient values are invalid

*NppStatus* **nppiGetAffineBound**(*NppiRect* oSrcROI, double aBound[2][2], const double aCoeffs[2][3])

Compute bounding-box of transformed image.

The method effectively computes the bounding box (axis aligned rectangle) of the transformed source ROI (see *nppiGetAffineQuad()*).

**Parameters**

- ▶ **oSrcROI** – The source ROI.
- ▶ **aBound** – The resulting bounding box.
- ▶ **aCoeffs** – The affine transform coefficients.

**Returns** Error codes:

- ▶ **NPP\_SIZE\_ERROR** Indicates an error condition if any image dimension has zero or negative value
- ▶ **NPP\_RECTANGLE\_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ **NPP\_COEFFICIENT\_ERROR** Indicates an error condition if coefficient values are invalid

### 1.10.17.3 Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a  $2 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates are computed as follows:

$$x' = c_{00} * x + c_{01} * y + c_{02} \quad y' = c_{10} * x + c_{11} * y + c_{12} \quad C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

Affine transforms can be understood as a linear transformation (traditional matrix multiplication) and a shift operation. The  $2 \times 2$  matrix

$$L = \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix}$$

represents the linear transform portion of the affine transformation. The vector

$$v = \begin{pmatrix} c_{02} \\ c_{12} \end{pmatrix}$$

represents the post-transform shift, i.e. after the pixel location is transformed by  $L$  it is translated by  $v$ .

#### 1.10.17.4 Affine Transform Batch

Details of the warp affine operation are described above in the WarpAffine section. WarpAffineBatch generally takes the same parameter list as WarpAffine except that there is a list of N instances of those parameters (N > 1) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The aTransformedCoeffs array is for internal use only and should not be directly initialized by the application. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of `oSrcRectROI` and `oDstRectROI` values are applied to each source image and destination image in the batch. Source and destination image sizes may vary but `oSmallestSrcSize` must be set to the smallest source and image size in the batch. The parameters in the `NppiWarpAffineBatchCXR` structure represent the corresponding per-image `nppiWarpAffine` parameters for each image in the batch. The `NppiWarpAffineBatchCXR` array must be in device memory. The `nppiWarpAffineBatchInit` function MUST be called AFTER the application has initialized the array of `NppiWarpAffineBatchCXR` structures and BEFORE calling any of the `nppiWarpAffineBatch` functions to so that the `aTransformed-Coeffs` array can be internally pre-initialized for each image in the batch. The batch size passed to `nppiWarpAffineBatchInit` must match the batch size passed to the corresponding warp affine batch function.

`WarpAffineBatch` supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
```

#### 1.10.17.4.1 Codes

The warp affine primitives return the following error codes:

- `NPP_RECTANGLE_ERROR` if either destination ROI width or height is less than 1 pixel.
- `NPP_INTERPOLATION_ERROR` if `eInterpolation` has an illegal value.
- `NPP_SIZE_ERROR` if source size width or height is less than 2 pixels.

#### 1.10.17.5 Common parameters for `nppiWarpAffineBatch` functions:

**param `oSmallestSrcSize`** Size in pixels of the entire smallest source image width and height, may be from different images.

**param `oSrcRectROI`** Region of interest in the source images.

**param `oDstRectROI`** Region of interest in the destination images.

**param `eInterpolation`** The type of `eInterpolation` to perform resampling. Currently limited to `NPPI_INTER_NN`, `NPPI_INTER_LINEAR`, or `NPPI_INTER_CUBIC`.

**param `pBatchList`** Device memory pointer to `nBatchSize` list of `NppiWarpAffineBatchCXR` structures.

**param `nBatchSize`** Number of `NppiWarpAffineBatchCXR` structures in this call (must be > 1).

**param `nppStreamCtx`** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.10.17.6 Backwards Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a  $2 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates fulfill the following properties:

$$\begin{aligned} x &= c_{00} * x' + c_{01} * y' + c_{02} & y &= c_{10} * x' + c_{11} * y' + c_{12} & C &= \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix} \end{aligned}$$

In other words, given matrix  $C$  the source image's shape is transformed to the destination image using the inverse matrix  $C^{-1}$ :

### 1.10.17.7 Quad-Based Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is computed such that it maps a quadrilateral in source image space to a quadrilateral in destination image space.

An affine transform is fully determined by the mapping of 3 discrete points. The following primitives compute an affine transformation matrix that maps the first three corners of the source quad to the first three vertices of the destination image quad. If the fourth vertices do not match the transform, an `NPP_AFFINE_QUAD_INCORRECT_WARNING` is returned by the primitive.

### 1.10.18.2 Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective transform is given as a  $3 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates are computed as follows:

$$x' = \frac{c_{00} * x + c_{01} * y + c_{02}}{c_{20} * x + c_{21} * y + c_{22}} \quad y' = \frac{c_{10} * x + c_{11} * y + c_{12}}{c_{20} * x + c_{21} * y + c_{22}}$$

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}$$

### 1.10.18.3 Perspective Transform Batch

Details of the warp perspective operation are described above in the WarpPerspective section. WarpPerspectiveBatch generally takes the same parameter list as WarpPerspective except that there is a list of N instances of those parameters (N > 1) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The aTransformedCoeffs array is for internal use only and should not be directly initialized by the application. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of oSrcRectROI and oDstRectROI values are applied to each source image and destination image in the batch. Source and destination image sizes may vary but oSmallestSrcSize must be set to the smallest source and image size in the batch. The parameters in the NppiWarpPerspectiveBatchCXR structure represent the corresponding per-image nppiWarpPerspective parameters for each image in the batch. The NppiWarpPerspectiveBatchCXR array must be in device memory. The nppiWarpPerspectiveBatchInit function MUST be called AFTER the application has initialized the array of NppiWarpPerspectiveBatchCXR structures and BEFORE calling any of the nppiWarpPerspectiveBatch functions to so that the aTransformedCoeffs array can be internally pre-initialized for each image in the batch. The batch size passed to nppiWarpPerspectiveBatchInit must match the batch size passed to the corresponding warp perspective batch function.

WarpPerspectiveBatch supports the following interpolation modes:

```

NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC

```

### 1.10.18.3.1 Common parameters for nppiWarpPerspectiveBatch functions:

**param oSmallestSrcSize** Size in pixels of the entire smallest source image width and height, may be from different images.

**param oSrcRectROI** Region of interest in the source images.

**param oDstRectROI** Region of interest in the destination images.

**param eInterpolation** The type of eInterpolation to perform resampling. Currently limited to NPPI\_INTER\_NN, NPPI\_INTER\_LINEAR, or NPPI\_INTER\_CUBIC.

**param pBatchList** Device memory pointer to nBatchSize list of NppiWarpPerspectiveBatchCXR structures.

**param nBatchSize** Number of NppiWarpPerspectiveBatchCXR structures in this call (must be > 1).

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

#### 1.10.18.4 Backwards Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective transform is given as a  $3 \times 3$  matrix  $C$ . A pixel location  $(x, y)$  in the source image is mapped to the location  $(x', y')$  in the destination image. The destination image coordinates fulfill the following properties:

$$x = \frac{c_{00} * x' + c_{01} * y' + c_{02}}{c_{20} * x' + c_{21} * y' + c_{22}} \quad y = \frac{c_{10} * x' + c_{11} * y' + c_{12}}{c_{20} * x' + c_{21} * y' + c_{22}}$$

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}$$

In other words, given matrix  $C$  the source image's shape is transformed to the destination image using the inverse matrix  $C^{-1}$ :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{bmatrix}$$

$$m_{22}x' = \frac{c_{00} * x + c_{01} * y + c_{02}}{c_{20} * x + c_{21} * y + c_{22}} \quad y' = \frac{c_{10} * x + c_{11} * y + c_{12}}{c_{20} * x + c_{21} * y + c_{22}}$$

### 1.12.1.2 Image Dilate Border

#### 1.12.1.2.1 Dilation with border control

Dilation computes the output pixel as the maximum pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum search. For gray scale dilation the mask contains signed mask values which are added to the corresponding source image sample value before determining the maximum value after clamping.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

## 1.12.2.2 Image Erode Border

### 1.12.2.2.1 Erosion with border control

Erosion computes the output pixel as the minimum pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the minimum search. For gray scale erosion the mask contains signed mask values which are added to the corresponding source image sample value before determining the minimum value after clamping.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.12.3.3 Image Morph Close Border

#### 1.12.3.3.1 MorphCloseBorder

Dilation followed by Erosion with border control.

Morphological close computes the output pixel as the maximum pixel value of the pixels under the mask followed by a second pass using the result of the first pass as input which outputs the minimum pixel value of the pixels under the same mask. Pixels who's corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphCloseBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphCloseBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.12.3.3.1.1 Common parameters for nppiMorphCloseBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** Source image starting point relative to pSrc.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pMask** Pointer to the start address of the mask array

**param oMaskSize** Width and Height mask array.

**param oAnchor** X and Y offsets of the mask origin frame of reference w.r.t the source pixel.

**param pBuffer** Pointer to device memory scratch buffer at least as large as value returned by the corresponding MorphGetBufferSize call.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.12.3.4 Image Morph Open Border

#### 1.12.3.4.1 MorphOpenBorder

Erosion followed by Dilation with border control.

Morphological open computes the output pixel as the minimum pixel value of the pixels under the mask followed by a second pass using the result of the first pass as input which outputs the maximum pixel value of the pixels under the same mask. Pixels whose corresponding mask values are zero do not participate in the minimum or maximum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphOpenBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphOpenBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.12.3.5 Image Morph Top Hat Border

#### 1.12.3.5.1 MorphToHatBorder

Source pixel minus the morphological open pixel result with border control.

Morphological top hat computes the output pixel as the source pixel minus the morphological open result of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphTopHatBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphTopHatBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.12.3.6 Image Morph Black Hat Border

#### 1.12.3.6.1 MorphBlackHatBorder

Morphological close pixel result minus source pixel with border control.

Morphological black hat computes the output pixel as the morphological close pixel value of the pixels under the mask minus the source pixel value. Pixels whose corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphBlackHatBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphBlackHatBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.12.3.7 Image Morph Gradient Border

#### 1.12.3.7.1 MorphGradientBorder

Morphological dilated pixel result minus morphological eroded pixel result with border control.

Morphological gradient computes the output pixel as the morphological dilated pixel value of the pixels under the mask minus the morphological eroded pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphGradientBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphGradientBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

## 1.13. Image Statistics Functions

Primitives for computing the statistical properties of an image.

Some statistical primitives also require scratch buffer during the computation. For details, please refer to *Scratch Buffer and Host Pointer*.

These functions can be found in the nppist library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

### 1.13.1. CommonGetBufferHostSizeParameters

Common parameters for nppiGetBufferHostSize functions include:

**param oSizeROI** *Region-Of-Interest (ROI)*.

**param hpBufferSize** Required buffer size. Important: hpBufferSize is a *host pointer*. *Scratch Buffer and Host Pointer*.

**param nppStreamCtx** Application Managed Stream Context.

**return** NPP\_NULL\_POINTER\_ERROR if hpBufferSize is 0 (NULL), *ROI Related Error Codes*.

## 1.13.2. Image Sum

### 1.13.2.1 Sum

Primitives for computing the sum of all the pixel values in an image.

#### Sum

Given an image  $pSrc$  with width  $W$  and height  $H$ , the sum will be computed as

$$Sum = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

All the results are stored in a 64-bit double precision format, except for two primitives `nppiSum_8u64s_C1R` and `nppiSum_8u64s_C4R`. The sum functions require additional scratch buffer for computations.

#### 1.13.2.2 Common parameters for nppiSum functions include:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pDeviceBuffer** *Pointer to the required device memory allocation, Scratch Buffer and Host Pointer. Use nppiSumGetBufferHostSize\_XX\_XXX to determine the minium number of bytes required.*

**param pSum** *Pointer to the computed sum.*

## 1.13.8. Image Mean

### 1.13.8.1 Mean

Primitives for computing the arithmetic mean of all the pixel values in an image.

#### Mean

Given an image *pSrc* with width *W* and height *H*, the arithmetic mean will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

The mean functions require additional scratch buffer for computations.

### 1.13.8.2 Common parameters for nppiMean functions include:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pMask** *Mask-Image Pointer.*

**param nMaskStep** *Mask-Image Line Step.*

**param nCOI** *Channel\_of\_Interest Number.*

**param pDeviceBuffer** *Pointer to the required device memory allocation, Scratch Buffer and Host Pointer Use nppiMeanGetBufferHostSize\_XX\_XXX to determine the minium number of bytes required.*

**param pMean** *Pointer to the computed mean result.*

**param nppStreamCtx** *Application Managed Stream Context.*

**return** *Image Data Related Error Codes, ROI Related Error Codes, or NPP\_COI\_ERROR if an invalid channel of interest is specified.s*

## 1.13.9. Image Mean StdDev

### 1.13.9.1 Mean\_StdDev

Primitives for computing both the arithmetic mean and the standard deviation of an image.

#### Mean\_StdDev

Given an image *pSrc* with width *W* and height *H*, the mean and the standard deviation will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

$$StdDev = \sqrt{\frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i) - Mean)^2}$$

The *Mean\_StdDev* primitives require additional scratch buffer for computations.

## 1.13.10. Image Norms

### 1.13.10.1 Image Norms

Primitives for computing the norms of an image, the norms of difference, and the relative errors of two images. Given an image *pSrc* with width *W* and height *H*,

1. The infinity norm (Norm\_Inf) is defined as the largest absolute pixel value of the image.
2. The L1 norm (Norm\_L1) is defined as the sum of the absolute pixel value of the image, i.e.,

$$Norm\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|$$

3. The L2 norm (Norm\_L2) is defined as the square root of the sum of the squared absolute pixel value of the image, i.e.,

$$Norm\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|^2}$$

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The infinity norm of difference (NormDiff\_Inf) is defined as the largest absolute difference between pixels of two images.
2. The L1 norm of difference (NormDiff\_L1) is defined as the sum of the absolute difference between pixels of two images, i.e.,

$$NormDiff\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

3. The L2 norm of difference (NormDiff\_L2) is defined as the squared root of the sum of the squared absolute difference between pixels of two images, i.e.,

$$NormDiff\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|^2}$$

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The relative error for the infinity norm of difference (NormRel\_Inf) is defined as NormDiff\_Inf divided by the infinity norm of the second image, i.e.,

$$NormRel\_Inf = \frac{NormDiff\_Inf}{Norm\_Inf_{src2}}$$

2. The relative error for the L1 norm of difference (NormRel\_L1) is defined as NormDiff\_L1 divided by the L1 norm of the second image, i.e.,

$$\text{NormRel\_L1} = \frac{\text{NormDiff\_L1}}{\text{Norm\_L1\_src2}}$$

3. The relative error for the L2 norm of difference (NormRel\_L2) is defined as NormDiff\_L2 divided by the L2 norm of the second image, i.e.,

$$\text{NormRel\_L2} = \frac{\text{NormDiff\_L2}}{\text{Norm\_L2\_src2}}$$

The norm functions require the addition device scratch buffer for the computations.

## 1.13.11. Image DotProd

### 1.13.11.1 DotProd

Primitives for computing the dot product of two images.

#### DotProd

Given two images  $pSrc1$  and  $pSrc2$  both with width  $W$  and height  $H$ , the dot product will be computed as

$$DotProd = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [pSrc1(j, i) \cdot pSrc2(j, i)]$$

The functions require additional scratch buffer for computations.

$$pDst(j, i) = \sqrt{\max(0, \frac{\sum(SqrIntegral) \cdot N - (\sum(Integral))^2}{N^2})}$$

where  $\sum(SqrIntegral) = pSqr[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSqr[j + oRect.y, i + oRect.x + oRect.width] - pSqr[j + oRect.y + oRect.height, i + oRect.x] + pSqr[j + oRect.y, i + oRect.x]$ ,  $\sum(Integral) = pSrc[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSrc[j + oRect.y, i + oRect.x + oRect.width] - pSrc[j + oRect.y + oRect.height, i + oRect.x] + pSrc[j + oRect.y, i + oRect.x]$ ,  $N = oRect.width \cdot oRect.height$ .

## 1.13.18. Image Histogram Even

### 1.13.18.1 HistogramEven

Primitives for computing the histogram of an image with evenly distributed bins.

#### HistogramEven

The *nLowerLevel* (inclusive) and *nUpperLevel* (exclusive) define the boundaries of the range, which are evenly segmented into *nLevel* – 1 bins.

The computed histogram is stored in *pHist*. The levels are calculated by another primitive *nppiEvenLevelsHost\_32s* and are stored in a host pointer *hpLevels*. The number of levels is also *nLevel* – 1. The histogram  $pHist[k]$  is defined as the total number of pixels that fall into the range:  $hpLevels[k] \leq pSrc(j, i) < hpLevels[k + 1]$ . ## 1.13.19. Image Histogram Range

### 1.13.19.1 HistogramRange

Primitives for computing the histogram of an image within specified ranges.

#### HistogramRange

The histogram is computed according to the ranges provided in  $pLevels$ .

The histogram  $pHist[k]$  is defined as the total number of pixels that fall into the range:  $pLevels[k] \leq pSrc(j, i) < pLevels[k + 1]$ . The number of the histogram bins is  $nLevel - 1$ . The functions require additional scratch buffer for computations.

### 1.13.19.2 Common parameters for nppiHistogramRange functions include:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pHist** Pointer to array that receives the computed histogram. The array must be of size  $nLevels - 1$ .

**param pLevels** Pointer to array containing the level sizes of the bins. The array must be of size  $nLevels$ .

**param nLevels** Number of levels in histogram.

**param pBuffer** Pointer to appropriately sized (`nppiHistogramRangeGetBufferSize_XX_XXX`) scratch buffer.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

## 1.13.20. Image Proximity

### 1.13.20.1 Image Proximity

Primitives for computing the proximity measure between a source image and a template image.

### 1.13.20.1.1 General Introduction

There are basically two approaches to compute the proximity measure for template matching, Euclidean distance and the cross correlation.

1.

Euclidean distance computes the sum of the squared distance (SSD) between the corresponding pixels of the source image and the template image. The smaller the distance is, the more similar the source image and the template image is around the pixel. The anchor of the template

image is used during the computations, which always lies in the geometric center of the image. Given a source image  $pSrc (W_s \times H_s)$  and a template image  $pTpl (W_t \times H_t)$ , the Euclidean distance  $D_{st}(c, r)$  between two images at pixel in row  $r$  and column  $c$  is computed as ( $s$  stands for source image and  $t$  for template image for short):

$$D_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]^2$$

2. Cross correlation computes the sum of the product between the corresponding pixels of the source image and the template image. The cross correlation  $R_{st}(c, r)$  is calculated as:

$$R_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) \cdot pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]$$

The larger the cross correlation value is, the more similar the source image and the template image is around the pixel.

3. The cross correlation  $R_{st}(c, r)$  is affected by the brightness of the images which may vary due to the lighting and exposure conditions. Therefore, NPP computes the cross correlation coefficient to circumvent this dependence. This is typically done at every step by subtracting the mean from every pixel value, i.e.,

$$\tilde{R}_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t] \cdot [pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2}) - Mean_s]$$

NPP computes the normalized values of Euclidean distance, cross correlation and the cross correlation coefficient.

1. The normalized Euclidean distance  $\sigma_{st}(c, r)$  is defined as:

$$\sigma_{st}(c, r) = \frac{D_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

2. The normalized cross correlation  $\rho_{st}(c, r)$  is defined as:

$$\rho_{st}(c, r) = \frac{R_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The  $R_{ss}(c, r)$  and  $R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$  denote the auto correlation of the source image and the template image individually. They are defined as:

$$R_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} pSrc(j, i)$$

$$R_{tt}\left(\frac{H_t}{2}, \frac{W_t}{2}\right) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} pTpl(j, i)$$

3. Similarly, the normalized cross correlation coefficient  $\gamma_{st}(c, r)$  is calculated as:

$$\gamma_{st}(c, r) = \frac{\tilde{R}_{st}(c, r)}{\sqrt{\tilde{R}_{ss}(c, r) \cdot \tilde{R}_{tt}\left(\frac{H_t}{2}, \frac{W_t}{2}\right)}}$$

The  $\tilde{R}_{ss}(c, r)$  and  $\tilde{R}_{tt}\left(\frac{H_t}{2}, \frac{W_t}{2}\right)$  are defined as:

$$\tilde{R}_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} [pSrc(j, i) - Mean_s]$$

$$\tilde{R}_{tt}\left(\frac{H_t}{2}, \frac{W_t}{2}\right) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t]$$

where  $Mean_t$  is the template mean minus the mean of the image in the region just under the template.

### 1.13.20.1.2 Categorizations

The Euclidean distance and the cross correlation are categorized into three types, full, same, and valid.

1. Full mode indicates that the anchor of the template image starts from the outside of the source image, assuming the out-of-boundary pixels are zero-padded. The size of the destination image is  $(W_s + W_t - 1) \times (H_s + H_t - 1)$ .
2. Same mode means that the anchor of the template image starts from the top left pixel of the source image. All the out-of-boundary pixels are also zero-padded. The size of the destination image is the same as the source one, i.e.,  $W_s \times H_s$ .
3. Valid mode indicates that there are no out-of-boundary readings from the source image. The anchor of the template image starts from the inside of the source image. The size of the destination image is  $(W_s - W_t + 1) \times (H_s - H_t + 1)$ .

## 1.13.29. Image Cross Correlation Same Norm Level

### 1.13.29.1 CrossCorrSame\_NormLevel

Primitives for computing the normalized cross correlation coefficient between two images with same mode.

### CrossCorrSame\_NormLevel

The functions compute the  $\gamma_{st}(c, r)$  in *General Introduction* with same mode (see *Categorizations*).

The functions require additional scratch buffer for computations.

Note: For maximum performance oSrcRoiSize.width MUST be an integer multiple of 4.

## 1.13.30. Image Cross Correlation Valid Norm Level

### 1.13.30.1 CrossCorrValid\_NormLevel

Primitives for computing the normalized cross correlation coefficient between two images with valid mode.

#### CrossCorrValid\_NormLevel

The functions compute the  $\gamma_{st}(c, r)$  in *General Introduction* with valid mode (see *Categorizations*).

The functions require additional scratch buffer for computations.

Note: For maximum performance oSrcRoiSize.width - oTplRoiSize + 1 MUST be an integer multiple of 4.

## 1.13.34. Image Quality Index

### 1.13.34.1 Image Quality Index

Primitives for computing the image quality index of two images.

#### QualityIndex

Given two images  $M$  and  $N$  (both  $W \times H$ ), the mathematical formula to calculate the image quality index  $Q$  between them is expressed as:

$$Q = \frac{4\sigma_{MN}\tilde{M}\tilde{N}}{[(\tilde{M}^2) + (\tilde{N}^2)][(\sigma_M)^2 + (\sigma_N)^2]}$$

where

$$\tilde{M} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} M(j, i)$$

$$\tilde{N} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} N(j, i)$$

$$\sigma_M = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}]^2}$$

$$\sigma_N = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [N(j, i) - \tilde{N}]^2}$$

$$\sigma_{MN} = \frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}][N(j, i) - \tilde{N}]$$

The functions require additional scratch buffer for computations.

## 1.13.36. Image Average Error

### 1.13.36.1 AverageError

Primitives for computing the average error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the average error is defined as:

$$AverageError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

where N stands for the number of channels. If the image is in complex format, the absolute value is used for computation.

## 1.13.37. Image Maximum Relative Error

### 1.13.37.1 MaximumRelativeError

Primitives for computing the maximum relative error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum relative error is defined as:

$$\text{MaximumRelativeError} = \max \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

If the image is in complex format, the absolute value is used for computation. For multiple channels, the maximum relative error of all the channels is returned.

## 1.13.38. Image Average Relative Error

### 1.13.38.1 AverageRelativeError

Primitives for computing the average relative error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum relative error is defined as:

$$\text{AverageRelativeError} = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

where *N* is the number of channels. If the image is in complex format, the absolute value is used for computation.

## 1.14. Image Threshold And Compare Operations

Methods for pixel-wise threshold and compare operations.

These functions can be found in the nppitc library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

### 1.14.1. Image Threshold Operations

#### 1.14.1.1 Threshold Operations

Threshold image pixels.

##### 1.14.1.1.1 Common parameters for nppiThreshold non-inplace and inplace functions:

**param nSrcDstStep** *In-Place-Image Line Step* for inplace functions.

**param pSrc** *Source-Image Pointer* for non-inplace functions.

**param nSrcStep** *Source-Image Line Step* for non-inplace functions.

**param pDst** *Destination-Image Pointer* for non-inplace functions.

Compare the pixels of two images or one image and a constant value and create a binary result image. In case of multi-channel image types, the condition must be fulfilled for all channels, otherwise the comparison is considered false. The “binary” result image is of type `8u_C1`. False is represented by 0, true by `NPP_MAX_8U`.

### 1.14.2.4 Compare Image Differences With Epsilon Operations

#### 1.14.2.4.1 Compare Image Differences With Epsilon Operations

Compare the pixels value differences of two images with an epsilon value and create a binary result image. In case of multi-channel image types, the condition must be fulfilled for all channels, otherwise the comparison is considered false. The “binary” result image is of type 8u\_C1. False is represented by 0, true by NPP\_MAX\_8U.

## 1.15. Image Memory Management Functions

Routines for allocating and deallocating pitched image storage.

These methods are provided for convenience. They allocate memory that may contain additional padding bytes at the end of each line of pixels. Though padding is not necessary for any of the NPP image-processing primitives to work correctly, its absence may cause severe performance degradation compared to properly padded images.

These functions can be found in the nppisu library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

## Image Memory Allocation

ImageAllocator methods for 2D arrays of data.

The allocators have width and height parameters to specify the size of the image data being allocated. They return a pointer to the newly created memory and return the numbers of bytes between successive lines.

If the memory allocation failed due to lack of free device memory or device memory fragmentation the routine returns 0.

All allocators return memory with line strides that are beneficial for performance. It is not mandatory to use these allocators. Any valid CUDA device-memory pointers can be used by the NPP primitives and there are no restrictions on line strides.

## 1.20.14. Signal Average Error

### 1.20.14.1 AverageError

Primitives for computing the Average error between two signals. Given two signals *pSrc1* and *pSrc2* both with length *N*, the average error is defined as

If the signal is in complex format, the absolute value of the complex number is used.

## 1.20.15. Signal Maximum Relative Error

### 1.20.15.1 MaximumRelativeError

Primitives for computing the MaximumRelative error between two signals. Given two signals *pSrc1* and *pSrc2* both with length *N*, the maximum relative error is defined as

$$\text{MaximumRelativeError} = \max \frac{|pSrc1(n) - pSrc2(n)|}{\max(|pSrc1(n)|, |pSrc2(n)|)}$$

If the signal is in complex format, the absolute value of the complex number is used.

## 1.20.16. Signal Average Relative Error

### 1.20.16.1 AverageRelativeError

Primitives for computing the AverageRelative error between two signals. Given two signals *pSrc1* and *pSrc2* both with length *N*, the average relative error is defined as

$$AverageRelativeError = \frac{1}{N} \sum_{n=0}^{N-1} \frac{|pSrc1(n) - pSrc2(n)|}{\max(|pSrc1(n)|, |pSrc2(n)|)}$$

If the signal is in complex format, the absolute value of the complex number is used.

## 1.21. Signal Memory Management Functions

Functions that provide memory management functionality like malloc and free.

### 1.21.1. Malloc

Signal-allocator methods for allocating 1D arrays of data in device memory. All allocators have size parameters to specify the size of the signal (1D array) being allocated.

The allocator methods return a pointer to the newly allocated memory of appropriate type. If device-memory allocation is not possible due to resource constraints the allocators return 0 (i.e. NULL pointer).

All signal allocators allocate memory aligned such that it is beneficial to the performance of the majority of the signal-processing primitives. It is no mandatory however to use these allocators. Any valid CUDA device-memory pointers can be passed to NPP primitives.
