## 1.7.3. Color Model Conversion Functions

Routines for converting between various image color models.

### 1.7.3.1 RGBToYUV

RGB to YUV color conversion.

Here is how NPP converts gamma corrected RGB or BGR to YUV. For digital RGB values in the range [0..255], Y has the range [0..255], U varies in the range [-112..+112], and V in the range [-157..+157]. To fit in the range of [0..255], a constant value of 128 is added to computed U and V values, and V is then saturated.

```
Npp32f nY = 0.299F * R + 0.587F * G + 0.114F * B;
Npp32f nU = (0.492F * ((Npp32f)nB - nY)) + 128.0F;
Npp32f nV = (0.877F * ((Npp32f)nR - nY)) + 128.0F;
if (nV > 255.0F)
    nV = 255.0F;
```

### 1.7.3.2 BGRTToYUV

BGR to YUV color conversion.

Here is how NPP converts gamma corrected RGB or BGR to YUV. For digital RGB values in the range [0..255], Y has the range [0..255], U varies in the range [-112..+112], and V in the range [-157..+157]. To fit in the range of [0..255], a constant value of 128 is added to computed U and V values, and V is then saturated.

```

Npp32f nY = 0.299F * R + 0.587F * G + 0.114F * B;
Npp32f nU = (0.492F * ((Npp32f)nB - nY)) + 128.0F;
Npp32f nV = (0.877F * ((Npp32f)nR - nY)) + 128.0F;
if (nV > 255.0F)
    nV = 255.0F;

```

### 1.7.3.78 YCCKToCMYK\_JPEG

This function partially converts JPEG YCCK to CMYK.

This is how NPP converts JPEG YCCK to CMYK. NPP only performs an initial YCC to RGB conversion using the 601 conversion coefficients and the RGB to CMY inversion leaving K unmodified. To complete this conversion to useful RGB values an additional RGB conversion needs to follow this function using the color profile contained in the YCCK JPEG file metadata section. NPP does not directly support this conversion but potentially `nppiColorTwist` can be used to perform it once the conversion coefficients are known.

```
Npp32f nY = static_cast<Npp32f>(Y);
Npp32f nC1 = static_cast<Npp32f>(Cb);
Npp32f nC2 = static_cast<Npp32f>(Cr);
Npp32f nR = nY + 1.402F * nC2 - 179.456F;
Npp32f nG = nY - 0.34414F * nC1 - 0.71414F * nC2 + 135.45984F;
Npp32f nB = nY + 1.772F * nC1 - 226.816F;

Npp8u nC = static_cast<Npp8u>(255.0F - nR);
Npp8u nM = static_cast<Npp8u>(255.0F - nG);
Npp8u nM = static_cast<Npp8u>(255.0F - nB);
Npp8u nK = K;

## 1.8. Image Data Exchange And Initialization Functions

Functions for initializing, copying and converting image data.

These functions can be found in the nppidei library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

## 1.8.1. Set

Functions for setting all pixels within the ROI to a specific value.

### 1.8.1.1 Common parameters for nppiSet functions:

**param nValue** The pixel value to be set.  
**param pDst** *Destination-Image Pointer.*  
**param nDstStep** *Destination-Image Line Step.*  
**param oSizeROI** *Region-Of-Interest (ROI).*  
**param nppiStreamCtx** Application Managed Stream Context.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

## 1.8.15. Convert Bit Depth

Functions for converting bit depth without scaling.

## 1.8.16. Convert To Increased Bit Depth

The integer conversion methods do not involve any scaling. Also, even when increasing the bit-depth loss of information may occur:

- ▶ When converting integers (e.g. *Npp32u*) to float (e.g. *Npp32f*) integer value not accurately representable by the float are rounded to the closest floating-point value.
- ▶ When converting signed integers to unsigned integers all negative values are lost (saturated to 0).

Note that all pointers and step sizes for images with 16f (*Npp16f*) data types perform best when they are at least 16 byte aligned.

### 1.8.16.1 Common parameters for nppiConvert to increased bit depth functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param nppStreamCtx** *Application Managed Stream Context.*

**return** *Image Data Related Error Codes, ROI Related Error Codes*

## 1.8.17. Convert To Decreased Bit Depth

The integer conversion methods do not involve any scaling. When converting floating-point values to integers the user may choose the most appropriate rounding-mode. Typically information is lost when converting to lower bit depth:

- ▶ All converted values are saturated to the destination type's range. E.g. any values larger than the largest value of the destination type are clamped to the destination's maximum.
- ▶ Converting floating-point values to integer also involves rounding, effectively losing all fractional value information in the process.

Note that all pointers and step sizes for images with 16f (*Npp16f*) data types perform best when they are at least 16 byte aligned.

## 1.8.18. Scale Bit Depth

Functions for scaling bit depth up or down.

## 1.8.19. Scale To Higher Bit Depth

Functions for scaling images to higher bit depth.

To map source pixel srcPixelValue to destination pixel dstPixelValue the following equation is used:

$$\text{dstPixelValue} = \text{dstMinRangeValue} + \text{scaleFactor} * (\text{srcPixelValue} - \text{srcMinRangeValue})$$

where  $\text{scaleFactor} = (\text{dstMaxRangeValue} - \text{dstMinRangeValue}) / (\text{srcMaxRangeValue} - \text{srcMinRangeValue})$ .

For conversions between integer data types, the entire integer numeric range of the input data type is mapped onto the entire integer numeric range of the output data type.

For conversions to floating point data types the floating point data range is defined by the user supplied floating point values of nMax and nMin which are used as the dstMaxRangeValue and dstMinRangeValue respectively in the scaleFactor and dstPixelValue calculations and also as the saturation values to which output data is clamped.

When converting from floating-point values to integer values, nMax and nMin are used as the srcMaxRangeValue and srcMinRangeValue respectively in the scaleFactor and dstPixelValue calculations. Output values are saturated and clamped to the full output integer pixel value range.

## 1.9. Image Filtering Functions

Linear and non-linear image filtering functions.

Filtering functions are classified as *Neighborhood Operations*. It is the user's responsibility to avoid *Sampling Beyond Image Boundaries*.

These functions can be found in the nppif library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

### 1.9.1. Image 1D Linear Filters

#### 1.9.1.1 1DLinearFilter

The set of 1D linear filtering functions available in the library.

#### 1.9.1.2 Image Filter Column

##### 1.9.1.2.1 FilterColumn

Apply convolution filter with user specified 1D column of weights.

##### 1.9.1.2.1.1 Common parameters for nppiFilterColumn functions:

Result pixel is equal to the sum of the products between the kernel coefficients (pKernel array) and corresponding neighboring column pixel values in the source image defined by nKernelDim and nAnchorY, divided by nDivisor.

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param nMaskSize** Length of the linear kernel array.

**param nAnchor** Y offset of the kernel origin frame of reference relative to the source pixel.

**param nDivisor** The factor by which the convolved summation from the Filter operation should be divided. If equal to the sum of coefficients, this will keep the maximum result value within full scale.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.1.3 Image Filter Column Border

#### 1.9.1.3.1 FilterColumnBorder

General purpose 1D convolution column filter with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.9.1.3.1.1 Common parameters for nppiFilterColumnBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param nMaskSize** Width of the kernel.

**param nAnchor** X offset of the kernel origin frame of reference relative to the source pixel.

**param nDivisor** The factor by which the convolved summation from the Filter operation should be divided. If equal to the sum of coefficients, this will keep the maximum result value within full scale.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.1.5 Image Filter Column Border 32f

#### 1.9.1.5.1 FilterColumnBorder32f

General purpose 1D column convolution filter using floating-point weights with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.9.1.6 Image Filter Row

#### 1.9.1.6.1 FilterRow

Apply convolution filter with user specified 1D row of weights.

Result pixel is equal to the sum of the products between the kernel coefficients (pKernel array) and corresponding neighboring row pixel values in the source image defined by nKernelDim and nAnchorX, divided by nDivisor.

##### 1.9.1.6.1.1 Common parameters for nppiFilterRow functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param nMaskSize** Length of the linear kernel array.

**param nAnchor** X offset of the kernel origin frame of reference relative to the source pixel.

**param nDivisor** The factor by which the convolved summation from the Filter operation should be divided. If equal to the sum of coefficients, this will keep the maximum result value within full scale.

### 1.9.1.7 Image Filter Row Border

#### 1.9.1.7.1 FilterRowBorder

General purpose 1D convolution row filter with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

##### 1.9.1.7.1.1 Common parameters for nppiFilterRowBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param nMaskSize** Width of the kernel.

**param nAnchor** X offset of the kernel origin frame of reference relative to the source pixel.

**param nDivisor** The factor by which the convolved summation from the Filter operation should be divided. If equal to the sum of coefficients, this will keep the maximum result value within full scale.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.1.9 Image Filter Row Border 32f

#### 1.9.1.9.1 FilterRowBorder32f

General purpose 1D row convolution filter using floating-point weights with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

##### 1.9.1.9.1.1 Common parameters for nppiFilterRowBorder32f functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param nMaskSize** Width of the kernel.

**param nAnchor** X offset of the kernel origin frame of reference relative to the source pixel.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.1.13 Image Filter 1D Window Sum Border

#### 1.9.1.13.1 1D Window Sum with Border Control

The set of 1D window sum functions with border control available in the library.

### 1.9.1.14 Image Filter 1D Window Column Sum Border

#### 1.9.1.14.1 1D Window Column Sum Border

1D mask Window Column Sum for 8 and 16 bit images with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the `NPP_BORDER_REPLICATE` border type operation is supported.

## 1.9.2. Image Convolution

### 1.9.2.1 Convolution

The set convolution functions available in the library.

### 1.9.2.2 Image Filter

#### 1.9.2.2.1 Filter

General purpose 2D convolution filter.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor.

#### 1.9.2.2.1.1 Common parameters for nppiFilter functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param oKernelSize** Width and Height of the rectangular kernel.

**param oAnchor** X and Y offsets of the kernel origin frame of reference relative to the source pixel.

**param nDivisor** The factor by which the convolved summation from the Filter operation should be divided. If equal to the sum of coefficients, this will keep the maximum result value within full scale.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

## 1.9.2.4 Image Filter Border

### 1.9.2.4.1 FilterBorder

General purpose 2D convolution filter with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

#### 1.9.2.4.1.1 Common parameters for nppiFilterBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param oKernelSize** Width and Height of the rectangular kernel.

**param oAnchor** X and Y offsets of the kernel origin frame of reference relative to the source pixel.

**param nDivisor** The factor by which the convolved summation from the Filter operation should be divided. If equal to the sum of coefficients, this will keep the maximum result value within full scale.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.2.5 Image Filter Border 32f

#### 1.9.2.5.1 FilterBorder32f

General purpose 2D convolution filter using floating-point weights with border control.

Pixels under the mask are multiplied by the respective weights in the mask and the results are summed. Before writing the result pixel the sum is scaled back via division by nDivisor. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

##### 1.9.2.5.1.1 Common parameters for nppiFilterBorder32f functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param pKernel** Pointer to the start address of the kernel coefficient array. Coefficients are expected to be stored in reverse order.

**param oKernelSize** Width and Height of the rectangular kernel.

**param oAnchor** X and Y offsets of the kernel origin frame of reference relative to the source pixel.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.3.5 Image Filter Threshold Adaptive Box Border

#### 1.9.3.5.1 FilterThresholdAdaptiveBoxBorder

Computes the average pixel values of the pixels under a square mask with border control. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. Once the neighborhood average around a source pixel is determined the source pixel is compared to the average - nDelta and if the source pixel is greater than that average the corresponding destination pixel is set to nValGT, otherwise nValLE.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param oMaskSize** Width and Height of the neighborhood region for the local Avg operation, Width and Height must be equal and odd.

### 1.9.4.3 Image Filter Max Border

#### 1.9.4.3.1 FilterMaxBorder

Result pixel value is the maximum of pixel values under the rectangular mask region with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

##### 1.9.4.3.1.1 Common parameters for nppiFilterMaxBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param oMaskSize** Width and Height of the neighborhood region for the local Max operation.

**param oAnchor** X and Y offsets of the kernel origin frame of reference relative to the source pixel.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.4.5 Image Filter Min Border

#### 1.9.4.5.1 FilterMinBorder

Result pixel value is the minimum of pixel values under the rectangular mask region with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

#### 1.9.4.5.1.1 Common parameters for nppiFilterMinBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param oMaskSize** Width and Height of the neighborhood region for the local Min operation.

## 1.9.5. Fixed Filters

### 1.9.5.1 Fixed Filters

Fixed filters perform linear filtering operations (such as convolutions) with predefined kernels of fixed sizes. Note that this section also contains a few dynamic kernel filters, namely `GaussAdvanced` and `Bilateral`.

Some of the fixed filters have versions with border control. For these functions, if any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the `NPP_BORDER_REPLICATE` border type operation is supported for these functions.

### FilterPrewittVertBorder

Filters the image using a vertical Prewitt filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

#### FilterRobertsDownBorder

Filters the image using a horizontal Roberts filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### FilterRobertsUpBorder

Filters the image using a vertical Roberts filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.9.5.11 Image Filter Laplace Border

#### 1.9.5.11.1 FilterLaplaceBorder

Filters the image using a Laplacian filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.9.5.11.1.1 Common parameters for nppiFilterLaplaceBorder functions:

$$\begin{pmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{pmatrix} \begin{pmatrix} -1 & -3 & -4 & -3 & -1 \\ -3 & 0 & 6 & 0 & -3 \\ -4 & 6 & 20 & 6 & -4 \\ -3 & 0 & 6 & 0 & -3 \\ -1 & -3 & -4 & -3 & -1 \end{pmatrix}$$

**param pSrc** *Source-Image Pointer.*

### 1.9.5.14 Image Filter Gauss Border

#### 1.9.5.14.1 FilterGaussBorder

Filters the image using a Gaussian filter kernel with border control. Use FilterGaussAdvancedBorder if you want to supply your own filter coefficients.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

Note that all FilterGaussBorder functions currently support mask sizes up to 15x15. Filter kernels for these functions are calculated using a sigma value of  $0.4F + (\text{mask width} / 2) * 0.6F$ .

### 1.9.5.14.1.1 Common parameters for nppiFilterGaussBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param eMaskSize** Enumeration value specifying the mask size.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

### 1.9.5.15 Image Filter Advanced Gauss Border

#### 1.9.5.15.1 FilterGaussAdvancedBorder

Filters the image using a separable Gaussian filter kernel with user supplied floating point coefficients with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Note that the performance of these functions can drop significantly for filter kernels with a very large number of taps.

Currently only the NPP\_BORDER\_REPLICATE and NPP\_BORDER\_MIRROR border type operations are supported.

### 1.9.5.16 Image Filter Gauss Pyramid Layer Down Border

#### 1.9.5.16.1 FilterGaussPyramidLayerDownBorder

Filters the image using a separable Gaussian filter kernel with user supplied floating point coefficients with downsampling and border control.

If the downsampling rate is equivalent to an integer value then unnecessary source pixels are just skipped. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_MIRROR and NPP\_BORDER\_REPLICATE border type operations are supported.

##### 1.9.5.16.1.1 Common parameters for nppiFilterGaussPyramidLayerDownBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param nRate** The downsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be  $> 1.0F$  and  $\leq 10.0F$ .

**param nFilterTaps** The number of filter taps where  $nFilterTaps = 2 * ((int)((float)ceil(radius) + 0.5F)) + 1$ .

**param pKernel** Pointer to an array of nFilterTaps kernel coefficients which sum to 1.0F.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

## Functions

*NppStatus* **nppiGetFilterGaussPyramidLayerDownBorderDstROI**(int nSrcROIWidth, int nSrcROIHeight, *NppiSize* \*pDstSizeROI, *Npp32f* nRate)

Calculate destination image SizeROI width and height from source image ROI width and height and downsampling rate.

It is highly recommended that this function be use to determine the destination image ROI for consistent results.

### Parameters

- ▶ **nSrcROIWidth** – The desired source image ROI width, must be  $\leq$  oSrcSize.width.
- ▶ **nSrcROIHeight** – The desired source image ROI height, must be  $\leq$  oSrcSize.height.
- ▶ **pDstSizeROI** – Host memory pointer to the destination image roi\_specification.
- ▶ **nRate** – The downsampling or upsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be  $> 1.0F$  and  $\leq 10.0F$ .

### 1.9.5.17 Image Filter Gauss Pyramid Layer Up Border

#### 1.9.5.17.1 FilterGaussPyramidLayerUpBorder

Filters the image using a separable Gaussian filter kernel with user supplied floating point coefficients with upsampling and border control.

If the upsampling rate is equivalent to an integer value then unnecessary source pixels are just skipped. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_MIRROR and NPP\_BORDER\_REPLICATE border type operations are supported.

##### 1.9.5.17.1.1 Common parameters for nppiFilterGaussPyramidLayerUpBorder functions:

**param pSrc** *Source-Image Pointer.*

**param nSrcStep** *Source-Image Line Step.*

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** *Destination-Image Pointer.*

**param nDstStep** *Destination-Image Line Step.*

**param oSizeROI** *Region-Of-Interest (ROI).*

**param nRate** The upsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be  $> 1.0F$  and  $\leq 10.0F$ .

**param nFilterTaps** The number of filter taps where  $nFilterTaps = 2 * ((int)((float)ceil(radius + 0.5F)) + 1$ .

**param pKernel** Pointer to an array of nFilterTaps kernel coefficients which sum to 1.0F.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** *Image Data Related Error Codes, ROI Related Error Codes*

## 1.9.5.18 Image Filter Bilateral Gauss Border

### 1.9.5.18.1 FilterBilateralGaussBorder

Filters the image using a bilateral Gaussian filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

For this filter the anchor point is always the central element of the kernel. Coefficients of the bilateral filter kernel depend on their position in the kernel and on the value of some source image pixels

overlayed by the filter kernel. Only source image pixels with both coordinates divisible by nDistance-BetweenSrcPixels are used in calculations.

The value of an output pixel  $d$  is

$$d = \frac{\sum_{h=-nRadius}^{nRadius} \sum_{w=-nRadius}^{nRadius} W1(h, w) \cdot W2(h, w) \cdot S(h, w)}{\sum_{h=-nRadius}^{nRadius} \sum_{w=-nRadius}^{nRadius} W1(h, w) \cdot W2(h, w)}$$

where  $h$  and  $w$  are the corresponding kernel width and height indexes,  $S(h,w)$  is the value of the source image pixel overlayed by filter kernel position  $(h,w)$ ,  $W1(h,w)$  is  $\text{func}(nValSquareSigma, (S(h,w) - S(0,0)))$  where  $S(0,0)$  is the value of the source image pixel at the center of the kernel,  $W2(h,w)$  is  $\text{func}(nPosSquareSigma, \text{sqrt}(h*h+w*w))$ , and  $\text{func}$  is the following formula

$$\text{func}(S, I) = \exp\left(-\frac{I^2}{2.0F \cdot S^2}\right)$$

Currently only the NPP\_BORDER\_REPLICATE border type operations are supported.

## 1.9.5.20 Image Filter High Pass Border

### 1.9.5.20.1 FilterHighPassBorder

Filters the image using a high-pass filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

## 1.9.5.22 Image Filter Low Pass Border

### 1.9.5.22.1 FilterLowPassBorder

Filters the image using a low-pass filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.9.5.22.1.1 Common parameters for nppiFilterLowPassBorder functions:

$$\begin{pmatrix} 1/9 & 1/9 & 1/9 \\ 1/9 & 1/9 & 1/9 \\ 1/9 & 1/9 & 1/9 \end{pmatrix} \begin{pmatrix} 1/25 & 1/25 & 1/25 & 1/25 & 1/25 \\ 1/25 & 1/25 & 1/25 & 1/25 & 1/25 \\ 1/25 & 1/25 & 1/25 & 1/25 & 1/25 \\ 1/25 & 1/25 & 1/25 & 1/25 & 1/25 \\ 1/25 & 1/25 & 1/25 & 1/25 & 1/25 \end{pmatrix}$$

### 1.9.5.25 Image Filter Unsharp Border

#### 1.9.5.25.1 FilterUnsharpBorder

Filters the image using a unsharp-mask sharpening filter kernel with border control.

The algorithm involves the following steps: Smooth the original image with a Gaussian filter, with the width controlled by the nRadius. Subtract the smoothed image from the original to create a high-pass filtered image. Apply any clipping needed on the high-pass image, as controlled by the nThreshold. Add a certain percentage of the high-pass filtered image to the original image, with the percentage controlled by the nWeight. In pseudocode this algorithm can be written as: HighPass = Image - Gaussian(Image) Result = Image + nWeight \* HighPass \* ( |HighPass| >= nThreshold ) where nWeight is the amount, nThreshold is the threshold, and >= indicates a Boolean operation, 1 if true, or 0 otherwise.

If any portion of the mask overlaps the source image boundary, the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

### 1.9.5.26 Image Filter Wiener Border

#### 1.9.5.26.1 FilterWienerBorder

Noise removal filtering of an image using an adaptive Wiener filter with border control.

Pixels under the source mask are used to generate statistics about the local neighborhood which are then used to control the amount of adaptive noise filtering locally applied.

Note that if the noise value for a particular channel is set to 0.0f then the output for that channel will contain the square of the variance of local pixels within `aMaskSize` surrounding each pixel in `oSizeROI`. Note that is unlikely to be useful unless the pixel data type is floating point due to result clamping. Output from these cases can then be passed through an `nppiMean` function call using the same `oSizeROI`. The square root for that channel from the `nppiMean` call result can then be used as a noise value for a future call to this function if there is no known preexisting noise value.

Currently only the `NPP_BORDER_REPLICATE` border type operation is supported.

### 1.9.5.26.1.1 Common parameters for nppiFilterWienerBorder functions:

For each pixel in the source image the function estimates the local mean and variance in the neighborhood defined by oMaskSize relative to the primary source pixel located at oAnchor.x and oAnchor.y. Given an oMaskSize with width  $W$  and height  $H$ , the mean, variance, and destination pixel value will be computed per channel as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

$$Variance^2 = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i)^2 - Mean^2)$$

$$pDst(j, i) = Mean + \frac{(Variance^2 - NoiseVariance^2)}{Variance^2} \cdot (pSrc(j, i) - Mean)$$

**param pSrc** Source-Image Pointer.

**param nSrcStep** Source-Image Line Step.

**param oSrcSize** Source image width and height in pixels relative to pSrc.

**param oSrcOffset** The pixel offset that pSrc points to relative to the origin of the source image.

**param pDst** Destination-Image Pointer.

**param nDstStep** Destination-Image Line Step.

**param oSizeROI** Region-Of-Interest (ROI).

**param oMaskSize** Pixel Width and Height of the rectangular region of interest surrounding the source pixel.

**param oAnchor** Positive X and Y relative offsets of primary pixel in region of interest surrounding the source pixel relative to bottom right of oMaskSize.

**param aNoise** Fixed size array of per-channel noise variance level value in range of 0.0F to 1.0F.

**param eBorderType** The border type operation to be applied at source image border boundaries.

**param nppStreamCtx** Application Managed Stream Context.

**return** Image Data Related Error Codes, ROI Related Error Codes

### 1.9.5.27 Image Filter Gradient Vector Prewitt Border

#### 1.9.5.27.1 GradientVectorPrewittBorder

RGB Color to Prewitt Gradient Vector conversion using user selected fixed mask size and gradient distance method. Functions support up to 4 optional single channel output gradient vectors, X (vertical), Y (horizontal), magnitude, and angle with user selectable distance methods. Output for a particular vector is disabled by supplying a NULL pointer for that vector. X and Y gradient vectors are in cartesian form in the destination data type.

Magnitude vectors are polar gradient form in the destination data type, angle is always in floating point polar gradient format. Only fixed mask sizes of 3x3 are supported. Only nppiNormL1 (sum) and nppiNormL2 (sqrt of sum of squares) distance methods are currently supported.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

### 1.9.5.27.1.1 Common parameters for nppiFilterGradientVectorPrewittBorder functions:

The following fixed kernel mask is used for producing the pDstX (vertical) output image.

$$\begin{pmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{pmatrix}$$

The following fixed kernel mask is used for producing the pDstY (horizontal) output image.

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{pmatrix}$$

For the C1R versions of the function the pDstMag output image value for L1 normalization consists of the absolute value of the pDstX value plus the absolute value of the pDstY value at that particular image pixel location. For the C1R versions of the function the pDstMag output image value for L2 normalization consists of the square root of the pDstX value squared plus the pDstY value squared at that particular image pixel location. For the C1R versions of the function the pDstAngle output image value consists of the arctangent (atan2) of the pDstY value and the pDstX value at that particular image pixel location.

For the C3C1R versions of the function, regardless of the selected normalization method, the L2 normalization value is first determined for each of the pDstX and pDstY values for each source channel then the largest L2 normalization value (largest gradient) is used to select which of the 3 pDstX channel values are output to the pDstX image or pDstY channel values are output to the pDstY image. For the C3C1R versions of the function the pDstMag output image value for L1 normalization consists of the same technique used for the C1R version for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 pDstMag channel values to output to the pDstMag image. For the C3C1R versions of the function the pDstMag output image value for L2 normalization consists of just outputting the largest per source channel L2 normalization value to the pDstMag image. For the C3C1R versions of the function the pDstAngle output image value consists of the same technique used for the C1R version calculated for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 angle values to output to the pDstAngle image.

The following fixed kernel mask is used for producing the `pDstX` (vertical) output image.

### 1.9.5.29 Image Filter Gradient Vector Sobel Border

#### 1.9.5.29.1 GradientVectorSobelBorder

RGB Color to Sobel Gradient Vector conversion using user selected fixed mask size and gradient distance method. Functions support up to 4 optional single channel output gradient vectors, X (vertical), Y (horizontal), magnitude, and angle with user selectable distance methods. Output for a particular vector is disabled by supplying a NULL pointer for that vector. X and Y gradient vectors are in cartesian form in the destination data type.

Magnitude vectors are polar gradient form in the destination data type, angle is always in floating point polar gradient format. Only fixed mask sizes of 3x3 and 5x5 are supported. Only nppiNormL1 (sum) and nppiNormL2 (sqrt of sum of squares) distance methods are currently supported.

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

##### 1.9.5.29.1.1 Common parameters for nppiFilterGradientVectorSobelBorder functions:

One of the following fixed kernel masks are used for producing the 3x3 or 5x5 pDstX (vertical) output image depending on selected mask size.

$$\begin{pmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{pmatrix}$$

$$\begin{pmatrix} -1 & -2 & 0 & 2 & 1 \\ -4 & -8 & 0 & 8 & 4 \\ -6 & -12 & 0 & 12 & 6 \\ -4 & -8 & 0 & 8 & 4 \\ -1 & -2 & 0 & 2 & 1 \end{pmatrix}$$

One of the following fixed kernel masks are used for producing the 3x3 or 5x5 pDstY (horizontal) output image depending on selected mask size.

$$\begin{pmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 4 & 6 & 4 & 1 \\ 2 & 8 & 12 & 8 & 2 \\ 0 & 0 & 0 & 0 & 0 \\ -2 & -8 & -12 & -8 & -2 \\ -1 & -4 & -6 & -4 & -1 \end{pmatrix}$$

For the C1R versions of the function the pDstMag output image value for L1 normalization consists of the absolute value of the pDstX value plus the absolute value of the pDstY value at that particular image pixel location. For the C1R versions of the function the pDstMag output image value for L2 normalization consists of the square root of the pDstX value squared plus the pDstY value squared at that particular image pixel location. For the C1R versions of the function the pDstAngle output image value consists of the arctangent (atan2) of the pDstY value and the pDstX value at that particular image pixel location.

For the C3C1R versions of the function, regardless of the selected normalization method, the L2 normalization value is first determined for each of the pDstX and pDstY values for each source channel then the largest L2 normalization value (largest gradient) is used to select which of the 3 pDstX channel values are output to the pDstX image or pDstY channel values are output to the pDstY image. For the C3C1R versions of the function the pDstMag output image value for L1 normalization consists of the same technique used for the C1R version for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 pDstMag channel values to output to the pDstMag image. For the C3C1R versions of the function the pDstMag output image value for L2 normalization consists of just outputting the largest per source channel L2 normalization value to the pDstMag image. For the C3C1R versions of the function the pDstAngle output image value consists of the same technique used for the C1R version calculated for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 angle values to output to the pDstAngle image.

## 1.9.6. Computer Vision Filtering Functions

### 1.9.6.1 Computer Vision

The set of computer vision functions available in the library.

## 1.9.6.2 Image Filter Distance Transform

### 1.9.6.2.1 FilterDistanceTransform

Performs Exact Euclidean Distance Transform function using the Parallel Banding Algorithm (PBA+) defined by Tiow-Seng Tan, et al paper named “Parallel Banding Algorithm to Compute Exact Distance Transform with the GPU” published dated August 8, 2019.

Output for these functions is an optional 16-bit signed integer voronoi diagram (pairs of signed 16 bit integer x, y distance values) and/or an optional true euclidean distance transform image generated from the internal voronoi diagram in either unsigned 16-bit truncated integer format or 32-bit floating point format. Additional optional output can include an signed 16-bit integer Voronoi diagram containing site indices and/or a signed 16-bit integer Voronoi diagram containing relative Manhattan distances to the closest sites. Minimum and maximum image ROI widths and heights are 64 and 32767.

Note that an input image that does not contain at least one site pixel is considered to be an invalid image. If you suspect that your input image may be invalid you can call an NPP function like `nppi_CountInRange()` first to confirm that the image is valid before calling the distance transform function.

The `nMinSiteValue` and `nMaxSiteValue` parameters can be used to control which source image pixels are considered sites (traditionally 0) and non-sites (everything else).

Antialiased true distance transform, when available, is only available as double precision floating point (`Npp64f`) output data only and is enabled by setting the `pAntialiasingDeviceBuffer` pointer parameter to a non-NULL value.

The algorithm used for antialiasing is derived from the `edtaa4` version from “Anti-aliased Euclidean distance transform” by Stefan Gustavson et. al. published in 2009 and is used under the permissions specified below.

Derived from `edtaa4.c` - compute the Euclidean distance transform of an image, with more accurate handling of 1 pixel wide anti-aliased edges.

This is a MEX-file for MATLAB. MATLAB is a product of The MathWorks, Inc.

Code in “`edtaa4func.c`” originally by Stefan Gustavson 1994, implemented from a verbal description in the PhD dissertation of Ingemar Ragnemalm, dept of EE, Linköping University.

1 channel 32-bit floating point grayscale to optional 1 channel 16-bit signed integer euclidean distance voronoi diagram and 32-bit floating point transform with optional sub-pixel shifts.

For this particular version of the function acceptable input pixel intensities are less than or equal to 0.0f for those fully outside of connected pixel regions, intensities with fractional parts between 0.0f and 1.0f representing the percentage of connected pixel region sub-pixel coverage within a particular pixel (region contour), and intensities greater than or equal to 1.0f for pixels that are fully contained within closed connected pixel regions. This function executes in two passes, the first pass prioritizes pixels outside of closed regions, the second pass prioritizes pixels within closed regions. The two passes are then merged on output. The function assumes that fully covered pixels have centers located at sub-pixel locations of .5,.5 . ### 1.9.6.3 Image Filter Harris Corners Border

#### 1.9.6.3.1 FilterHarrisCornersBorder

Performs Harris Corner detection on a single channel 8-bit grayscale image and outputs a single channel 32-bit floating point image consisting the corner response at each pixel of the image.

The algorithm consists of two phases. The first phase generates the floating point product of XX, YY, and XY gradients at each pixel in the image. The type of gradient used is controlled by the eFilterType and eMaskSize parameters. The second phase averages those products over a window of either 3x3 or 5x5 pixels around the center pixel then generates the Harris corner response at that pixel which is output in the destination image. The Harris response value is determined as  $H = ((XX * YY - XY * XY) - (nK * ((XX + YY) * (XX + YY)))) * nScale$ .

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

### Functions

### 1.9.6.4 Image Filter Hough Line

#### 1.9.6.4.1 FilterHoughLine

Extracts Hough lines from a single channel 8-bit binarized (0, 255) source feature (canny edges, etc.) image.

Outputs a list of lines in point polar format representing the length (rho) and angle (theta) of each line from the origin of the normal to the line using the formula  $\rho = x \cos(\theta) + y \sin(\theta)$ . The level of discretization, nDelta, is specified as an input parameter. The performance and effectiveness of this function highly depends on this parameter with higher performance for larger numbers and more detailed results for lower numbers. Also, lines are not guaranteed to be added to the pDeviceLines list in the same order from one call to the next. However, all of the same lines will still be generated as long as nMaxLineCount is set large enough so that they all can fit in the list. To convert lines in point polar format back to cartesian lines use the following formula:

```
Npp32f nHough = ((sqrt(2.0F) * static_cast<Npp32f>(oSizeROI.height > oSizeROI.width ?
↪oSizeROI.height
                                                                    :
↪oSizeROI.width)) / 2.0F);
int nAccumulatorsHeight = nDelta.rho > 1.0F ? static_cast<int>(ceil(nHough * 2.0F))
                                                                    : static_cast<int>(ceil((nHough * 2.0F) /
↪nDelta.rho));
int nCenterX = oSizeROI.width >> 1;
```

(continues on next page)

(continued from previous page)

```

int nCenterY = oSizeROI.height >> 1;
Npp32f nThetaRad = static_cast<Npp32f>(deviceline.theta) * 0.0174532925199433F;
Npp32f nSinTheta = sin(nThetaRad);
Npp32f nCosTheta = cos(nThetaRad);

### 1.9.6.5 Image Filter Histogram Of Oriented Gradients Border

#### 1.9.6.5.1 HistogramOfOrientedGradientsBorder

Performs Histogram Of Oriented Gradients operation on source image generating separate windows of Histogram Descriptors for each requested location.

This function implements the simplest form of functionality described by N. Dalal and B. Triggs. Histograms of Oriented Gradients for Human Detection. INRIA, 2005. It supports overlapped contrast normalized block histogram output with L2 normalization only, no threshold clipping, and no pre or post gaussian smoothing of input images or histogram output values. It supports both single channel grayscale source images and three channel color images. For color images, the color channel with the highest magnitude value is used as that pixel's magnitude. Output is row order only. Descriptors are output consecutively with no separation padding if multiple descriptor output is requested (one descriptor per source image location). For example, common HOG parameters are 9 histogram bins per 8 by 8 pixel cell, 2 by 2 cells per block, with a descriptor window size of 64 horizontal by 128 vertical pixels yielding 7 by 15 overlapping blocks (1 cell overlap in both horizontal and vertical directions). This results in 9 bins \* 4 cells \* 7 horizontal overlapping blocks \* 15 vertical overlapping blocks or 3780 32-bit floating point output values (bins) per descriptor window.

The number of horizontal overlapping block histogram bins per descriptor window width is determined by  $((oHOGConfig.detectionWindowSize.width / oHOGConfig.histogramBlockSize) * 2) - 1) * oHOGConfig.nHistogramBins$ . The number of vertical overlapping block histograms per descriptor window height is determined by  $((oHOGConfig.detectionWindowSize.height / oHOGConfig.histogramBlockSize) * 2) - 1)$ . The offset of each descriptor window in the descriptors output buffer is therefore horizontal histogram bins per descriptor window width \* vertical histograms per descriptor window height 32-bit floating point values relative to the previous descriptor window output.

The algorithm uses a 1D centered derivative mask of  $[-1, 0, +1]$  when generating input magnitude and angle gradients. Magnitudes are added to the two nearest histogram bins of oriented gradients between 0 and 180 degrees using a weighted linear interpolation of each magnitude value across the 2 nearest angular bin orientations. 2D overlapping blocks of histogram bins consisting of the bins from 2D arrangements of cells are then contrast normalized using L2 normalization and output to the corresponding histogram descriptor window for that particular window location in the window locations list.

Some restrictions include:

```
#define NPP_HOG_MAX_CELL_SIZE           (16)
#define NPP_HOG_MAX_BLOCK_SIZE         (64)
#define NPP_HOG_MAX_BINS_PER_CELL      (16)

#define NPP_HOG_MAX_OVERLAPPING_BLOCKS_PER_DESCRIPTOR (256)
#define NPP_HOG_MAX_DESCRIPTOR_LOCATIONS_PER_CALL (128)
```

Currently only the NPP\_BORDER\_REPLICATE border type operation is supported.

## Functions

`NppStatus nppiHistogramOfGradientsBorderGetBufferSize`(const `NppiHOGConfig` oHOGConfig, const `NppiPoint` \*hpLocations, int nLocations, `NppiSize` oSizeROI, int \*hpBufferSize)

Validates requested HOG configuration and calculates scratch buffer size needed for the HistogramOfGradientsBorder function based on requested HOG configuration, source image ROI, and number and locations of descriptor window locations.

### Parameters

- ▶ **oHOGConfig** – Requested HOG configuration parameters structure.
- ▶ **hpLocations** – Host pointer to array of NppiPoint source pixel starting locations of requested descriptor windows. Important: hpLocations is a *host pointer*.
- ▶ **nLocations** – Number of NppiPoint in pLocations array.
- ▶ **oSizeROI** – *Region-Of-Interest (ROI)* of source image.
- ▶ **hpBufferSize** – Required buffer size in bytes. Important: hpBufferSize is a *host pointer*. *Scratch Buffer and Host Pointer*.

**Returns** *Image Data Related Error Codes, ROI Related Error Codes*

*NppStatus* **nppiHistogramOfGradientsBorderGetDescriptorsSize**(const *NppiHOGConfig* oHOGConfig, int nLocations, int \*hpDescriptorsSize)

Validates requested HOG configuration and calculates output window descriptors buffer size needed for the HistogramOfGradientsBorder function based on requested HOG configuration, and number of descriptor window locations, one descriptor window is output for each location.

Descriptor windows are located sequentially and contiguously in the descriptors buffer.

The number of horizontal overlapping block histogram bins per descriptor window width is determined by  $((\text{oHOGConfig.detectionWindowSize.width} / \text{oHOGConfig.histogramBlockSize}) * 2) - 1$  \* oHOGConfig.nHistogramBins. The number of vertical overlapping block histograms per descriptor window height is determined by  $((\text{oHOGConfig.detectionWindowSize.height} / \text{oHOGConfig.histogramBlockSize}) * 2) - 1$ . The offset of each descriptor window in the descriptors output buffer is therefore horizontal histogram bins per descriptor window width \* vertical histograms per descriptor window height floating point values relative to the previous descriptor window output.

#### Parameters

- ▶ **oHOGConfig** – Requested HOG configuration parameters structure.
- ▶ **nLocations** – Number of *NppiPoint* in *pLocations* array.
- ▶ **hpDescriptorsSize** – Required buffer size in bytes of output windows descriptors for *nLocations* descriptor windows. Important: *hpDescriptorsSize* is a *host pointer*.

## 1.9.7. Image Filter Flood Fill

### 1.9.7.1 FloodFill

Flood fill a connected region of an image with a specified new value.

## FloodFillGetBufferSize

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer.

The application allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

*NppStatus* **nppiFloodFillGetBufferSize**(*NppiSize* oSizeROI, int \*hpBufferSize)

Calculate scratch buffer size needed for the FloodFill function based on destination image oSizeROI width and height.

### Parameters

- ▶ **oSizeROI** – *Region-Of-Interest (ROI)*.
- ▶ **hpBufferSize** – Required buffer size in bytes.

## 1.9.7.2 Flood Fill

### 1.9.7.2.1 FloodFill

In place flood fill of a region of pixels connected to the pixel at the seed pixel location in an image with a new pixel value.

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the pConnectedRegion *NppiConnectedRegion* structure in host memory. The oBoundingBox x and y will be set to the left and top coordinates and width and height will be set to the right bottom coordinates of the bounding box relative to pSrcDst. Set pConnectedRegion to NULL if not required. Requesting pConnectedRegion information may slightly degrade performance.

### 1.9.7.3 Flood Fill Boundary

#### 1.9.7.3.1 FloodFillBoundary

In place flood fill of a region of pixels connected to the pixel at the seed pixel location in an image with a new pixel value. Also fill boundary of filled region with a specified color.

Before calling any of the FloodFill functions the application first needs to call the `FloodFillGetBufferSize` function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the `pBuffer` parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the `pConnectedRegion` `NppiConnectedRegion` structure in host memory. The `oBoundingBox` `x` and `y` will be set to the left and top coordinates and `width` and `height` will be set to the right bottom coordinates of the bounding box relative to `pSrcDst`. Set `pConnectedRegion` to NULL if not required. Requesting `pConnectedRegion` information may slightly degrade performance.

### 1.9.7.4 Flood Fill Range

#### 1.9.7.4.1 FloodFillRange

In place flood fill of a region of pixels connected to the pixel at the seed pixel location and with a Pixel value  $\geq$  Min and  $\leq$  Max in an image with a new pixel value.

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the pConnectedRegion NppiConnectedRegion structure in host memory. The oBoundingBox x and y will be set to the left and top coordinates and width and height will be set to the right bottom coordinates of the bounding box relative to pSrcDst. Set pConnectedRegion to NULL if not required. Requesting pConnectedRegion information may slightly degrade performance.

### 1.9.7.5 Flood Fill Range Boundary

#### 1.9.7.5.1 FloodFillRangeBoundary

In place flood fill of a region of pixels connected to the pixel at the seed pixel location and with a Pixel value  $\geq$  Min and  $\leq$  Max in an image with a new pixel value. Also fill boundary of filled region with a specified color.

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the pConnectedRegion NppiConnectedRegion structure in host memory. The oBoundingBox x and y will be set to the left and top coordinates and width and height will be set to the right bottom coordinates of the bounding box relative to pSrcDst. Set pConnectedRegion to NULL if not required. Requesting pConnectedRegion information may slightly degrade performance.

### 1.9.7.6 Flood Fill Gradient

#### 1.9.7.6.1 FloodFillGradient

In place flood fill of a region of pixels connected to the pixel at the seed pixel location and with an original pixel value including seed - Min to seed + Max in an image with a new pixel value.

In place flood fill of a region of pixels connected to the pixel at the seed pixel location in an image with a new pixel value.

Before calling any of the FloodFill functions the application first needs to call the *FloodFillGetBufferSize* function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the *pBuffer* parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the *pConnectedRegion* *NppiConnectedRegion* structure in host memory. The *oBoundingBox* *x* and *y* will be set to the left and top coordinates and *width* and *height* will be set to the right bottom coordinates of the bounding box relative to *pSrcDst*. Set *pConnectedRegion* to NULL if not required. Requesting *pConnectedRegion* information may slightly degrade performance.

### 1.9.7.7 Flood Fill Gradient Boundary

#### 1.9.7.7.1 FloodFillGradientBoundary

In place flood fill of a region of pixels connected to the pixel at the seed pixel location and with an original pixel value including seed - Min to seed + Max in an image with a new pixel value. Also fill boundary of filled region with a specified color.

In place flood fill of a region of pixels connected to the pixel at the seed pixel location in an image with a new pixel value.

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the pConnectedRegion NppiConnectedRegion structure in host memory. The oBoundingBox x and y will be set to the left and top coordinates and width and height will be set to the right bottom coordinates of the bounding box relative to pSrcDst. Set pConnectedRegion to NULL if not required. Requesting pConnectedRegion information may slightly degrade performance.

## 1.9.8. Label Markers

### 1.9.8.1 LabelMarkers

Generate image connected region label markers to be used for later image segmentation.

These functions have been deprecated. Use LabelMarkersUF functions instead.

#### LabelMarkersUFGetBufferSize

Before calling any of the LabelMarkersUF functions the application first needs to call the LabelMarkersGetBufferSize function to determine the amount of device memory to allocate as a working buffer.

The application allocated device memory is then passed as the pBuffer parameter to the corresponding LabelMarkersUF function.

*NppStatus* **nppiLabelMarkersUFGetBufferSize\_32u\_C1R**(*NppiSize* oSizeROI, int \*hpBufferSize)

Calculate scratch buffer size needed 1 channel 32-bit unsigned integer LabelMarkersUF function based on destination image oSizeROI width and height.

#### Parameters

- ▶ **oSizeROI** – *Region-Of-Interest (ROI)*.
- ▶ **hpBufferSize** – Required buffer size in bytes.

## 1.9.8.2 LabelMarkersUF

### 1.9.8.2.1 LabelMarkersUF

Generate image connected region label markers to be used for later image segmentation.

A connected region is any pixel region where all pixels in the region have the same pixel value. Note that marker label IDs generally increase in value from image left to right and top to bottom they are not generated in any particular order and there may be numeric gaps between sequential marker IDs. To limit the number of marker IDs generated the application should pass the image through a threshold filter before calling this function. Doing so however does not necessarily limit the maximum marker ID value generated by this function. Note that these functions currently only support image ROI sizes up to 4 gigapixels. Also note that while these functions support destination image pitches that are not exactly equal to `oSizeROI.width * sizeof(Npp32u)` it can avoid a `cudaMemcpyAsync()` call to copy the final result from the working buffer to the destination image if the pitch exactly equals `oSizeROI.width * sizeof(Npp32u)`.

Before calling any of the LabelMarkersUF functions the application first needs to call the `LabelMarkersUFGetBufferSize` to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the `pBuffer` parameter to the corresponding LabelMarkersUF function.

The algorithm used in this implementation is based on the one described in “An Optimized Union-Find Algorithm for Connected Components Labeling Using GPUs” by Jun Chen and others.

Note that the destination image in these functions must be allocated with `cudaMalloc()` and NOT `cudaMallocPitch()`. Also the pitch of the output image MUST be set to `oSizeROI.width * sizeof(Npp32u)`.

### 1.9.8.3 Label MarkersUF Batch

#### 1.9.8.3.1 LabelMarkersUFBatch

Generate image connected region label markers to be used for later image segmentation for a batched list of images.

A connected region is any pixel region where all pixels in the region have the same pixel value. Note that marker label IDs generally increase in value from image left to right and top to bottom they are not generated in any particular order and there may be numeric gaps between sequential marker IDs. To limit the number of marker IDs generated the application should pass the image through a threshold filter before calling this function. Doing so however does not necessarily limit the maximum marker ID value generated by this function. Note that these functions currently only support image ROI sizes up to 4 gigapixels. Also note that these functions work directly in the destination image so destination pitch MUST be equal to destination ROI.width \* sizeof(Npp32u) and even if destination pitch is greater than that the output will be in that format. If this doesn't work for you use the single image version of these functions or cudaMemCopy2D can be called for each output image to restore the original pitch. Note that all source and destination images in the batch list must contain enough device memory to support the full ROI size. ROIs in descriptor lists are ignored in these functions.

The algorithm used in this implementation is based on the one described in "An Optimized Union-Find Algorithm for Connected Components Labeling Using GPUs" by Jun Chen and others.

Note that the destination images in these functions must be allocated with cudaMalloc() and NOT cudaMallocPitch(). Also the pitch of the output image MUST be set to oSizeROI.width \* sizeof(Npp32u).

### 1.9.8.4 LabelMarkersUF Batch Advanced

#### 1.9.8.4.1 LabelMarkersUFBatchAdvanced

Generate image connected region label markers to be used for later image segmentation for a batched list of images.

A connected region is any pixel region where all pixels in the region have the same pixel value. Note that marker label IDs generally increase in value from image left to right and top to bottom they are not generated in any particular order and there may be numeric gaps between sequential marker IDs. To limit the number of marker IDs generated the application should pass the image through a threshold filter before calling this function. Doing so however does not necessarily limit the maximum marker ID value generated by this function. Note that these functions currently only support image ROI sizes up to 4 gigapixels. Also note that these functions work directly in the destination image so destination pitch MUST be equal to destination ROI.width \* sizeof(Npp32u) for each destination image in the list and even if the destination image pitch is greater than that of the output will be in that format. If this doesn't work for you use the single image version of these functions or cudaMemCopy2D can be called for each output image to restore the original pitch. Note that all source and destination images in the batch list must contain enough device memory to contain their specified ROI size.

The algorithm used in this implementation is based on the one described in “An Optimized Union-Find Algorithm for Connected Components Labeling Using GPUs” by Jun Chen and others.

Note that the destination images in these functions must be allocated with cudaMalloc() and NOT cudaMallocPitch(). Also the pitch of the output image MUST be set to oSizeROI.width \* sizeof(Npp32u).

## 1.10. Image Geometry Transforms Functions

Routines manipulating an image geometry.

These functions can be found in the nppig library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

## 1.10.1. Geometric Transform API Specifics

This section covers some of the unique API features common to the geometric transform primitives.

## 1.10.2. Geometric Transforms and ROIs

Geometric transforms operate on source and destination ROIs. The way these ROIs affect the processing of pixels differs from other (non geometric) image-processing primitives: Only pixels in the intersection of the destination ROI and the transformed source ROI are being processed.

The typical processing proceeds as follows:

1. Transform the rectangular source ROI (given in source image coordinates) into the destination image space. This yields a quadrilateral.
2. Write only pixels in the intersection of the transformed source ROI and the destination ROI.

## 1.10.3. Pixel Interpolation

The majority of image geometry transform operation need to perform a resampling of the source image as source and destination pixels are not coincident.

NPP supports the following pixel interpolation modes (in order from fastest to slowest and lowest to highest quality):

- ▶ nearest neighbor
- ▶ linear interpolation
- ▶ cubic convolution
- ▶ supersampling
- ▶ interpolation using Lanczos window function

## 1.10.4. Resize Error Codes

The resize primitives return the following error codes:

- `NPP_WRONG_INTERSECTION_ROI_ERROR` indicates an error condition if `srcROIrect` has no intersection with the source image.
- `NPP_RESIZE_NO_OPERATION_ERROR` if either destination ROI width or height is less than 1 pixel.
- `NPP_RESIZE_FACTOR_ERROR` Indicates an error condition if either `nXFactor` or `nYFactor` is less than or equal to zero or in the case of `NPPI_INTER_SUPER` are ↪not both downscaling.
- `NPP_INTERPOLATION_ERROR` if `eInterpolation` has an illegal value.
- `NPP_SIZE_ERROR` if source size width or height is less than 2 pixels.
- `NPP_RECTANGLE_ERROR` if either destination ROI width or height is less than 1 pixel.

## 1.10.5. ResizeSqrPixel

ResizeSqrPixel functions attempt to choose source pixels that would approximately represent the center of the destination pixels. It does so by using the following scaling formula to select source pixels for interpolation:

```
nAdjustedXFactor = 1.0 / nXFactor;
nAdjustedYFactor = 1.0 / nYFactor;
nAdjustedXShift = nXShift * nAdjustedXFactor + ((1.0 - nAdjustedXFactor) * 0.5);
nAdjustedYShift = nYShift * nAdjustedYFactor + ((1.0 - nAdjustedYFactor) * 0.5);
nSrcX = nAdjustedXFactor * nDstX - nAdjustedXShift;
nSrcY = nAdjustedYFactor * nDstY - nAdjustedYShift;
```

ResizeSqrPixel functions support the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_CUBIC2P_BSPLINE
NPPI_INTER_CUBIC2P_CATMULLROM
NPPI_INTER_CUBIC2P_B05C03
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

In the ResizeSqrPixel functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

### GetResizeRect

Returns NppiRect which represents the offset and size of the destination rectangle that would be generated by resizing the source NppiRect by the requested scale factors and shifts.
