1.11.19.2 Affine Transform Utility Functions

The set of affine transform utility functions.

Functions

NppStatus **nppiGetAffineTransform**(*NppiRect* oSrcROI, const double aQuad[4][2], double aCoeffs[2][3])

Computes affine transform coefficients based on source ROI and destination quadrilateral.

The function computes the coefficients of an affine transformation that maps the given source ROI (axis aligned rectangle with integer coordinates) to a quadrilateral in the destination image.

An affine transform in 2D is fully determined by the mapping of just three vertices. This function's API allows for passing a complete quadrilateral effectively making the problem overdetermined. What this means in practice is, that for certain quadrilaterals it is not possible to find an affine transform that would map all four corners of the source ROI to the four vertices of that quadrilateral.

The function circumvents this problem by only looking at the first three vertices of the destination image quadrilateral to determine the affine transformation's coefficients. If the destination quadrilateral is indeed one that cannot be mapped using an affine transformation the function informs the user of this situation by returning a **NPP_AFFINE_QUAD_INCORRECT_WARNING**.

Parameters

- ▶ **oSrcROI** – The source ROI. This rectangle needs to be at least one pixel wide and high. If either width or height are less than one an NPP_RECTANGLE_ERROR is returned.
- ▶ **aQuad** – The destination quadrilateral.
- ▶ **aCoeffs** – The resulting affine transform coefficients.

Returns

Error codes:

- ▶ NPP_SIZE_ERROR Indicates an error condition if any image dimension has zero or negative value
- ▶ NPP_RECTANGLE_ERROR Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ NPP_COEFFICIENT_ERROR Indicates an error condition if coefficient values are invalid
- ▶ NPP_AFFINE_QUAD_INCORRECT_WARNING Indicates a warning when quad does not conform to the transform properties. Fourth vertex is ignored, internally computed coordinates are used instead

NppStatus **nppiGetAffineQuad**(*NppiRect* oSrcROI, double aQuad[4][2], const double aCoeffs[2][3])

Compute shape of transformed image.

This method computes the quadrilateral in the destination image that the source ROI is transformed into by the affine transformation expressed by the coefficients array (aCoeffs).

Parameters

- ▶ **oSrcROI** – The source ROI.
- ▶ **aQuad** – The resulting destination quadrangle.
- ▶ **aCoeffs** – The affine transform coefficients.

Returns

Error codes:

- ▶ NPP_SIZE_ERROR Indicates an error condition if any image dimension has zero or negative value
- ▶ NPP_RECTANGLE_ERROR Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ NPP_COEFFICIENT_ERROR Indicates an error condition if coefficient values are invalid

NppStatus **nppiGetAffineBound**(*NppiRect* oSrcROI, double aBound[2][2], const double aCoeffs[2][3])

Compute bounding-box of transformed image.

The method effectively computes the bounding box (axis aligned rectangle) of the transformed source ROI (see *nppiGetAffineQuad()*).

Parameters

- ▶ **oSrcROI** – The source ROI.
- ▶ **aBound** – The resulting bounding box.
- ▶ **aCoeffs** – The affine transform coefficients.

Returns

Error codes:

- ▶ **NPP_SIZE_ERROR** Indicates an error condition if any image dimension has zero or negative value
- ▶ **NPP_RECTANGLE_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ **NPP_COEFFICIENT_ERROR** Indicates an error condition if coefficient values are invalid

1.11.19.3 Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a 2×3 matrix C . A pixel location (x, y) in the source image is mapped to the location (x', y') in the destination image. The destination image coordinates are computed as follows:

$$x' = c_{00} * x + c_{01} * y + c_{02} \quad y' = c_{10} * x + c_{11} * y + c_{12} \quad C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

Affine transforms can be understood as a linear transformation (traditional matrix multiplication) and a shift operation. The 2×2 matrix

$$L = \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix}$$

represents the linear transform portion of the affine transformation. The vector

$$v = \begin{pmatrix} c_{02} \\ c_{12} \end{pmatrix}$$

represents the post-transform shift, i.e. after the pixel location is transformed by L it is translated by v .

1.11.19.4 Affine Transform Batch

Details of the warp affine operation are described above in the WarpAffine section. WarpAffineBatch generally takes the same parameter list as WarpAffine except that there is a list of N instances of those parameters ($N > 1$) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The `aTransformedCoeffs` array is for internal use only and should not be directly initialized by the application. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of `oSrcRectROI` and `oDstRectROI` values are applied to each source image and destination image in the batch. Source and destination image sizes may vary but `oSmallestSrcSize` must be set to the smallest source and image size in the batch. The parameters in the `NppiWarpAffineBatchCXR` structure represent the corresponding per-image `nppiWarpAffine` parameters for each image in the batch. The `NppiWarpAffineBatchCXR` array must be in device memory. The `nppiWarpAffineBatchInit` function MUST be called AFTER the application has initialized the array of `NppiWarpAffineBatchCXR` structures and BEFORE calling any of the `nppiWarpAffineBatch` functions to so that the `aTransformedCoeffs` array can be internally pre-initialized for each image in the batch. The batch size passed to `nppiWarpAffineBatchInit` must match the batch size passed to the corresponding warp affine batch function.

WarpAffineBatch supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
```

1.11.19.4.1 Codes

The warp affine primitives return the following error codes:

- `NPP_RECTANGLE_ERROR` if either destination ROI width or height is less than 1 pixel.
- `NPP_INTERPOLATION_ERROR` if `eInterpolation` has an illegal value.
- `NPP_SIZE_ERROR` if source size width or height is less than 2 pixels.

1.11.19.5 Common parameters for `nppiWarpAffineBatch` functions:

param `oSrcRectROI`

1.11.19.6 Backwards Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a 2×3 matrix C . A pixel location (x, y) in the source image is mapped to the location (x', y') in the destination image. The destination image coordinates fulfil the following properties:

$$\begin{aligned} x &= c_{00} * x' + c_{01} * y' + c_{02} & y &= c_{10} * x' + c_{11} * y' + c_{12} & C &= \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix} \end{aligned}$$

In other words, given matrix C the source image's shape is transformed to the destination image using the inverse matrix C^{-1} :

$$\begin{aligned} M &= C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \end{bmatrix} \\ m_{12}x' &= m_{00} * x + m_{01} * y + m_{02} & y' &= m_{10} * x + m_{11} * y + m_{12} \end{aligned}$$

1.11.19.7 Quad-Based Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is computed such that it maps a quadrilateral in source image space to a quadrilateral in destination image space.

An affine transform is fully determined by the mapping of 3 discrete points. The following primitives compute an affine transformation matrix that maps the first three corners of the source quad are mapped to the first three vertices of the destination image quad. If the fourth vertices do not match the transform, an NPP_AFFINE_QUAD_INCORRECT_WARNING is returned by the primitive.

1.11.20.2 Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective transform is given as a 3×3 matrix C . A pixel location (x, y) in the source image is mapped to the location (x', y') in the destination image. The destination image coordinates are computed as follows:

$$x' = \frac{c_{00} * x + c_{01} * y + c_{02}}{c_{20} * x + c_{21} * y + c_{22}} \quad y' = \frac{c_{10} * x + c_{11} * y + c_{12}}{c_{20} * x + c_{21} * y + c_{22}}$$

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}$$

1.11.20.3 Perspective Transform Batch

Details of the warp perspective operation are described above in the WarpPerspective section. WarpPerspectiveBatch generally takes the same parameter list as WarpPerspective except that there is a list of N instances of those parameters (N > 1) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The aTransformed-Coeffs array is for internal use only and should not be directly initialized by the application. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of `oSrcRectROI` and `oDstRectROI` values are applied to each source image and destination image in the batch. Source and destination image sizes may vary but `oSmallestSrcSize` must be set to the smallest source and image size in the batch. The parameters in the *NppiWarpPerspectiveBatchCXR* structure represent the corresponding per-image `nppiWarpPerspective` parameters for each image in the batch. The *NppiWarpPerspectiveBatchCXR* array must be in device memory. The `nppiWarpPerspectiveBatchInit` function MUST be called AFTER the application has initialized the array of *NppiWarpPerspectiveBatchCXR* structures and BEFORE calling any of the `nppiWarpPerspectiveBatch` functions to so that the `aTransformedCoeffs` array can be internally pre-initialized for each image in the batch. The batch size passed to `nppiWarpPerspectiveBatchInit` must match the batch size passed to the corresponding warp perspective batch function.

`WarpPerspectiveBatch` supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
```

1.11.20.3.1 Common parameters for `nppiWarpPerspectiveBatch` functions:

1.11.20.4 Backwards Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective transform is given as a 3×3 matrix C . A pixel location (x, y) in the source image is mapped to the location (x', y') in the destination image. The destination image coordinates fulfill the following properties:

$$x = \frac{c_{00} * x' + c_{01} * y' + c_{02}}{c_{20} * x' + c_{21} * y' + c_{22}} \quad y = \frac{c_{10} * x' + c_{11} * y' + c_{12}}{c_{20} * x' + c_{21} * y' + c_{22}}$$

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}$$

In other words, given matrix C the source image's shape is transformed to the destination image using

the inverse matrix C^{-1} :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \\ m_{20} & m_{21} & m_{22} \end{bmatrix}$$

$$m_{22}x' = \frac{c_{00} * x + c_{01} * y + c_{02}}{c_{20} * x + c_{21} * y + c_{22}} \quad y' = \frac{c_{10} * x + c_{11} * y + c_{12}}{c_{20} * x + c_{21} * y + c_{22}}$$

1.13.1.2 Image Dilate Border

1.13.1.2.1 Dilation with border control

Dilation computes the output pixel as the maximum pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum search. For gray scale dilation the mask contains signed mask values which are added to the corresponding source image sample value before determining the maximum value after clamping.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.13.2.2 Image Erode Border

1.13.2.2.1 Erosion with border control

Erosion computes the output pixel as the minimum pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the minimum search. For gray scale erosion the mask contains signed mask values which are added to the corresponding source image sample value before determining the minimum value after clamping.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.13.2.2.1.1 Common parameters for nppiErodeBorder functions:

param pSrc
Source-Image Pointer.

param nSrcStep
Source-Image Line Step.

param oSrcSize
Source image width and height in pixels relative to pSrc.

param oSrcOffset
Source image starting point relative to pSrc.

param pDst
Destination-Image Pointer.

param nDstStep
Destination-Image Line Step.

param oSizeROI
Region-Of-Interest (ROI).

param pMask
Pointer to the start address of the mask array

param oMaskSize
Width and Height mask array.

param oAnchor
X and Y offsets of the mask origin frame of reference w.r.t the source pixel.

param eBorderType
The border type operation to be applied at source image border boundaries.

param nppStreamCtx
Application Managed Stream Context.

return

1.13.3.3 Image Morph Close Border

1.13.3.3.1 MorphCloseBorder

Dilation followed by Erosion with border control.

Morphological close computes the output pixel as the maximum pixel value of the pixels under the mask followed by a second pass using the result of the first pass as input which outputs the minimum pixel value of the pixels under the same mask. Pixels who's corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphCloseBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphCloseBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.13.3.4 Image Morph Open Border

1.13.3.4.1 MorphOpenBorder

Erosion followed by Dilation with border control.

Morphological open computes the output pixel as the minimum pixel value of the pixels under the mask followed by a second pass using the result of the first pass as input which outputs the maximum pixel value of the pixels under the same mask. Pixels whose corresponding mask values are zero do not participate in the minimum or maximum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphOpenBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphOpenBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.13.3.5 Image Morph Top Hat Border

1.13.3.5.1 MorphToHatBorder

Source pixel minus the morphological open pixel result with border control.

Morphological top hat computes the output pixel as the source pixel minus the morphological open result of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphTopHatBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphTopHatBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.13.3.7 Image Morph Gradient Border

1.13.3.7.1 MorphGradientBorder

Morphological dilated pixel result minus morphological eroded pixel result with border control.

Morphological gradient computes the output pixel as the morphological dilated pixel value of the pixels under the mask minus the morphological eroded pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphGradientBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphGradientBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.14.2. Image Sum

1.14.2.1 Sum

Primitives for computing the sum of all the pixel values in an image.

Sum

Given an image $pSrc$ with width W and height H , the sum will be computed as

$$Sum = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

All the results are stored in a 64-bit double precision format, except for two primitives $nppiSum\_8u64s\_C1R$ and $nppiSum\_8u64s\_C4R$. The sum functions require additional scratch buffer for computations.

param nSrcStep

Source-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param pDeviceBuffer

1.14.8. Image Mean

1.14.8.1 Mean

Primitives for computing the arithmetic mean of all the pixel values in an image.

Mean

Given an image *pSrc* with width *W* and height *H*, the arithmetic mean will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

The mean functions require additional scratch buffer for computations.

param oSizeROI

param pDeviceBuffer

1.14.9. Image Mean StdDev

1.14.9.1 Mean_StdDev

Primitives for computing both the arithmetic mean and the standard deviation of an image.

Mean_StdDev

Given an image *pSrc* with width *W* and height *H*, the mean and the standard deviation will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$
$$StdDev = \sqrt{\frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i) - Mean)^2}$$

The Mean_StdDev primitives require additional scratch buffer for computations.

1.14.10. Image Norms

1.14.10.1 Image Norms

Primitives for computing the norms of an image, the norms of difference, and the relative errors of two images. Given an image *pSrc* with width *W* and height *H*,

1. The infinity norm (Norm_Inf) is defined as the largest absolute pixel value of the image.
2. The L1 norm (Norm_L1) is defined as the sum of the absolute pixel value of the image, i.e.,

$$Norm\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|$$

.

3. The L2 norm (Norm_L2) is defined as the square root of the sum of the squared absolute pixel value of the image, i.e.,

$$Norm\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|^2}$$

.

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The infinity norm of difference (NormDiff_Inf) is defined as the largest absolute difference between pixels of two images.

2. The L1 norm of difference (NormDiff_L1) is defined as the sum of the absolute difference between pixels of two images, i.e.,

$$NormDiff\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

3. The L2 norm of difference (NormDiff_L2) is defined as the squared root of the sum of the squared absolute difference between pixels of two images, i.e.,

$$NormDiff\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|^2}$$

Given two images $pSrc1$ and $pSrc2$ both with width W and height H ,

1. The relative error for the infinity norm of difference (NormRel_Inf) is defined as NormDiff_Inf divided by the infinity norm of the second image, i.e.,

$$NormRel\_Inf = \frac{NormDiff\_Inf}{Norm\_Inf_{src2}}$$

2. The relative error for the L1 norm of difference (NormRel_L1) is defined as NormDiff_L1 divided by the L1 norm of the second image, i.e.,

$$NormRel\_L1 = \frac{NormDiff\_L1}{Norm\_L1_{src2}}$$

3. The relative error for the L2 norm of difference (NormRel_L2) is defined as NormDiff_L2 divided by the L2 norm of the second image, i.e.,

$$NormRel\_L2 = \frac{NormDiff\_L2}{Norm\_L2_{src2}}$$

The norm functions require the addition device scratch buffer for the computations.

1.14.11. Image DotProd

1.14.11.1 DotProd

Primitives for computing the dot product of two images.

DotProd

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the dot product will be computed as

$$DotProd = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [pSrc1(j, i) \cdot pSrc2(j, i)]$$

The functions require additional scratch buffer for computations.

1.14.11.2 Common parameters for nppiDotProd functions include:

- param pSrc1**
Source-Image Pointer.
- param nSrc1Step**
Source-Image Line Step.
- param pSrc2**
Source-Image Pointer.
- param nSrc2Step**
Source-Image Line Step.
- param oSizeROI**
Region-Of-Interest (ROI).

param pDp

Pointer to the computed dot product of the two images.

param pDeviceBuffer

Pointer to the required device memory allocation, *Scratch Buffer and Host Pointer*.

param nppStreamCtx

Application Managed Stream Context.

1.14.17. Image RectStdDev

1.14.17.1 RectStdDev

Primitives for computing the standard deviation of the integral images. The function computes the standard deviation of the pixel in the rectangular window with the integral image *pSrc* and the squared integral image *pSqr*, which can be obtained by calling *Integral* and *SqrIntegral*.

The standard deviation of the pixel (j, i) can be computed using the formula:

$$pDst(j, i) = \sqrt{\max(0, \frac{\sum(SqrIntegral) \cdot N - (\sum(Integral))^2}{N^2})}$$

where $\sum(SqrIntegral) = pSqr[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSqr[j + oRect.y, i + oRect.x + oRect.width] - pSqr[j + oRect.y + oRect.height, i + oRect.x] + pSqr[j + oRect.y, i + oRect.x]$,

$$\sum(Integral) = pSrc[j + oRect.y + oRect.height, i + oRect.x + oRect.width] - pSrc[j + oRect.y, i + oRect.x + oRect.width] - pSrc[j + oRect.y + oRect.height, i + oRect.x] + pSrc[j + oRect.y, i + oRect.x], N = oRect.width \cdot oRect.height.$$

The size of the *pSrc* and *pSqr* should be $(oSizeROI.width + oRect.x + oRect.width, oSizeROI.height + oRect.y + oRect.height)$.

1.14.18. Image Histogram Even

1.14.18.1 HistogramEven

Primitives for computing the histogram of an image with evenly distributed bins.

HistogramEven

The $nLowerLevel$ (inclusive) and $nUpperLevel$ (exclusive) define the boundaries of the range, which are evenly segmented into $nLevel - 1$ bins.

The computed histogram is stored in $pHist$. The levels are calculated by another primitive $nppiEvenLevelsHost_32s$ and are stored in a host pointer $hpLevels$. The number of levels is also $nLevel - 1$. The histogram $pHist[k]$ is defined as the total number of pixels that fall into the range: $hpLevels[k] \leq pSrc(j, i) < hpLevels[k + 1]$. The functions require additional scratch buffer for computations.

1.14.18.2 Common parameters for nppiHistogramEven functions include:

param pSrc

Source-Image Pointer.

param nSrcStep

Source-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param pHist

param nLevels

Number of levels.

param nLowerLevel

Lower boundary of lowest level bin.

param nUpperLevel

Upper boundary of highest level bin.

param pBuffer

Pointer to appropriately sized scratch buffer.

param nppStreamCtx

Application Managed Stream Context.

return

1.14.19. Image Histogram Range

1.14.19.1 HistogramRange

Primitives for computing the histogram of an image within specified ranges.

HistogramRange

The histogram is computed according to the ranges provided in *pLevels*.

The histogram $pHist[k]$ is defined as the total number of pixels that fall into the range: $pLevels[k] \leq pSrc(j, i) < pLevels[k + 1]$. The number of the histogram bins is $nLevel - 1$. The functions require additional scratch buffer for computations.

1.14.19.2 Common parameters for nppiHistogramRange functions include:

param pSrc

Source-Image Pointer.

param nSrcStep

Source-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param pHist

Pointer to array that receives the computed histogram. The array must be of size $nLevels - 1$.

param pLevels

Pointer to array containing the level sizes of the bins. The array must be of size $nLevels$.

param nLevels

Number of levels in histogram.

param pBuffer

Pointer to appropriately sized (`nppiHistogramRangeGetBufferSize_XX_XXX`) scratch buffer.

param nppStreamCtx

Application Managed Stream Context.

1.14.20. Image Proximity

1.14.20.1 Image Proximity

Primitives for computing the proximity measure between a source image and a template image.

1.14.20.1.1 General Introduction

There are basically two approaches to compute the proximity measure for template matching, Euclidean distance and the cross correlation.

1.

Euclidean distance computes the sum of the squared distance (SSD) between the corresponding pixels of the source image and the template image. The smaller the distance is, the more similar the source image and the template image is around the pixel. The anchor of the template

image is used during the computations, which always lies in the geometric center of the image. Given a source image $pSrc (W_s \times H_s)$ and a template image $pTpl (W_t \times H_t)$, the Euclidean distance $D_{st}(c, r)$ between two images at pixel in row r and column c is computed as (s stands for source image and t for template image for short):

$$D_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]^2$$

2. Cross correlation computes the sum of the product between the corresponding pixels of the source image and the template image. The cross correlation $R_{st}(c, r)$ is calculated as:

$$R_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) \cdot pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]$$

The larger the cross correlation value is, the more similar the source image and the template image is around the pixel.

3. The cross correlation $R_{st}(c, r)$ is affected by the brightness of the images which may vary due to the lighting and exposure conditions. Therefore, NPP computes the cross correlation coefficient to circumvent this dependence. This is typically done at every step by subtracting the mean from every pixel value, i.e.,

$$\tilde{R}_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t] \cdot [pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2}) - Mean_s]$$

NPP computes the normalized values of Euclidean distance, cross correlation and the cross correlation coefficient.

1. The normalized Euclidean distance $\sigma_{st}(c, r)$ is defined as:

$$\sigma_{st}(c, r) = \frac{D_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

2. The normalized cross correlation $\rho_{st}(c, r)$ is defined as:

$$\rho_{st}(c, r) = \frac{R_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The $R_{ss}(c, r)$ and $R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$ denote the auto correlation of the source image and the template image individually. They are defined as:

$$R_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} pSrc(j, i)$$

$$R_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} pTpl(j, i)$$

3. Similarly, the normalized cross correlation coefficient $\gamma_{st}(c, r)$ is calculated as:

$$\gamma_{st}(c, r) = \frac{\tilde{R}_{st}(c, r)}{\sqrt{\tilde{R}_{ss}(c, r) \cdot \tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The $\tilde{R}_{ss}(c, r)$ and $\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$ are defined as:

$$\tilde{R}_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} [pSrc(j, i) - Mean_s]$$

$$\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t]$$

where $Mean_t$ is the template mean minus the mean of the image in the region just under the template.

1.14.20.1.2 Categorizations

The Euclidean distance and the cross correlation are categorized into three types, full, same, and valid.

1. Full mode indicates that the anchor of the template image starts from the outside of the source image, assuming the out-of-boundary pixels are zero-padded. The size of the destination image is $(W_s + W_t - 1) \times (H_s + H_t - 1)$.
2. Same mode means that the anchor of the template image starts from the top left pixel of the source image. All the out-of-boundary pixels are also zero-padded. The size of the destination image is the same as the source one, i.e., $W_s \times H_s$.
3. Valid mode indicates that there are no out-of-boundary readings from the source image. The anchor of the template image starts from the inside of the source image. The size of the destination image is $(W_s - W_t + 1) \times (H_s - H_t + 1)$.

1.14.29. Image Cross Correlation Same Norm Level

1.14.29.1 CrossCorrSame_NormLevel

Primitives for computing the normalized cross correlation coefficient between two images with same mode.

CrossCorrSame_NormLevel

The functions compute the $\gamma_{st}(c, r)$ in *General Introduction* with same mode (see *Categorizations*).

The functions require additional scratch buffer for computations.

Note: For maximum performance oSrcRoiSize.width MUST be an integer multiple of 4.

1.14.34.1 Image Quality Index

Primitives for computing the image quality index of two images.

QualityIndex

Given two images M and N (both $W \times H$), the mathematical formula to calculate the image quality index Q between them is expressed as:

$$Q = \frac{4\sigma_{MN}\tilde{M}\tilde{N}}{[(\tilde{M}^2) + (\tilde{N}^2)][(\sigma_M)^2 + (\sigma_N)^2]}$$

where

$$\tilde{M} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} M(j, i)$$

$$\tilde{N} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} N(j, i)$$

$$\sigma_M = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}]^2}$$

$$\sigma_N = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [N(j, i) - \tilde{N}]^2}$$

$$\sigma_{MN} = \frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}][N(j, i) - \tilde{N}]$$

1.14.35. Image Maximum Error

1.14.35.1 MaximumError

Primitives for computing the maximum error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum error is defined as the largest absolute difference between pixels of two images. If the image is in complex format, the absolute value of the complex number is provided.

1.14.36.1 AverageError

Primitives for computing the average error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the average error is defined as:

$$AverageError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

where N stands for the number of channels. If the image is in complex format, the absolute value is used for computation.

1.14.37. Image Maximum Relative Error

1.14.37.1 MaximumRelativeError

Primitives for computing the maximum relative error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum relative error is defined as:

$$\text{MaximumRelativeError} = \max \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

If the image is in complex format, the absolute value is used for computation. For multiple channels, the maximum relative error of all the channels is returned.

1.14.38. Image Average Relative Error

1.14.38.1 AverageRelativeError

Primitives for computing the average relative error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum relative error is defined as:

$$AverageRelativeError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

where *N* is the number of channels. If the image is in complex format, the absolute value is used for computation.

Methods for pixel-wise threshold and compare operations.

These functions can be found in the *nppitc* library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

1.15.1. Image Threshold Operations

1.15.1.1 Threshold Operations

Threshold image pixels.

1.15.1.1.1 Common parameters for *nppiThreshold* non-inplace and inplace functions:

Source-Image Pointer for non-inplace functions.

param nSrcStep

Source-Image Line Step for non-inplace functions.

param pDst

Destination-Image Pointer for non-inplace functions.

param nDstStep

1.15.2. Image Comparison Operations

1.15.2.1 Comparison Operations

Compare the pixels of two images or one image and a constant value and create a binary result image. In case of multi-channel image types, the condition must be fulfilled for all channels, otherwise the comparison is considered false. The “binary” result image is of type 8u_C1. False is represented by 0, true by NPP_MAX_8U.

1.15.2.3 Compare Image With Constant Operations

1.15.2.3.1 Compare Image With Constant Operations

Compare the pixels of an image with a constant value and create a binary result image. In case of multi-channel image types, the condition must be fulfilled for all channels, otherwise the comparison is considered false. The "binary" result image is of type 8u_C1. False is represented by 0, true by NPP_MAX_8U.

1.15.2.3.1.1 Common parameters for nppiCompareC functions:

param pSrc

Source-Image Pointer.

param nSrcStep

Source-Image Line Step.

param nConstant

constant value for single channel functions.

param pConstants

pointer to a list of constant values, one per color channel for multi-channel functions.

param pDst

Destination-Image Pointer.

param nDstStep

Destination-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param eComparisonOperation

1.15.2.5 Compare Image Difference To Constant With Epsilon Operations

1.15.2.5.1 Compare Image Difference With Constant Within Epsilon Operations

Compare differences between image pixels and constant within an epsilon value and create a binary result image. 1.16. Image Memory Management Functions

Routines for allocating and deallocating pitched image storage.

These methods are provided for convenience. They allocate memory that may contain additional padding bytes at the end of each line of pixels. Though padding is not necessary for any of the NPP image-processing primitives to work correctly, its absence may cause severe performance degradation compared to properly padded images.

These functions can be found in the nppisu library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

Image Memory Allocation

ImageAllocator methods for 2D arrays of data.

The allocators have width and height parameters to specify the size of the image data being allocated. They return a pointer to the newly created memory and return the numbers of bytes between successive lines.

If the memory allocation failed due to lack of free device memory or device memory fragmentation the routine returns 0.

All allocators return memory with line strides that are beneficial for performance. It is not mandatory to use these allocators. Any valid CUDA device-memory pointers can be used by the NPP primitives and there are no restrictions on line strides.

1.21.15. Signal Maximum Relative Error

1.21.15.1 MaximumRelativeError

Primitives for computing the MaximumRelative error between two signals. Given two signals *pSrc1* and *pSrc2* both with length *N*, the maximum relative error is defined as

1.22. Signal Memory Management Functions

Functions that provide memory management functionality like malloc and free.

1.22.1. Malloc

Signal-allocator methods for allocating 1D arrays of data in device memory. All allocators have size parameters to specify the size of the signal (1D array) being allocated.

The allocator methods return a pointer to the newly allocated memory of appropriate type. If device-memory allocation is not possible due to resource constraints the allocators return 0 (i.e. NULL pointer).

All signal allocators allocate memory aligned such that it is beneficial to the performance of the majority of the signal-processing primitives. It is no mandatory however to use these allocators. Any valid CUDA device-memory pointers can be passed to NPP primitives.

Functions

Npp8u ***nppsMalloc_8u**(size_t nSize)

8-bit unsigned signal allocator.

Parameters

- **nSize** – Number of unsigned chars in the new signal.

Returns

A pointer to the new signal. 0 (NULL-pointer) indicates that an error occurred during allocation.

Npp8s ***nppsMalloc_8s**(size_t nSize)

8-bit signed signal allocator.

Parameters

- **nSize** – Number of (signed) chars in the new signal.

Returns
