1.10.5.14 Image Filter Gauss Border

1.10.5.14.1 FilterGaussBorder

Filters the image using a Gaussian filter kernel with border control. Use FilterGaussAdvancedBorder if you want to supply your own filter coefficients.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

Note that all FilterGaussBorder functions currently support mask sizes up to 15x15. Filter kernels for these functions are calculated using a sigma value of $0.4F + (\text{mask width} / 2) * 0.6F$.

1.10.5.16 Image Filter Gauss Pyramid Layer Down Border

1.10.5.16.1 FilterGaussPyramidLayerDownBorder

Filters the image using a separable Gaussian filter kernel with user supplied floating point coefficients with downsampling and border control.

If the downsampling rate is equivalent to an integer value then unnecessary source pixels are just skipped. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_MIRROR and NPP_BORDER_REPLICATE border type operations are supported.

1.10.5.16.1.1 Common parameters for nppiFilterGaussPyramidLayerDownBorder functions:

param pSrc

Source-Image Pointer.

param nSrcStep

Source-Image Line Step.

param oSrcSize

Source image width and height in pixels relative to pSrc.

param oSrcOffset

The pixel offset that pSrc points to relative to the origin of the source image.

param pDst

Destination-Image Pointer.

param nDstStep

Destination-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param nRate

The downsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be > 1.0F and <= 10.0F.

param nFilterTaps

The number of filter taps where $nFilterTaps = 2 * ((int)((float)ceil(radius) + 0.5F)) + 1$.

param pKernel

Pointer to an array of nFilterTaps kernel coefficients which sum to 1.0F.

param eBorderType

Functions

NppStatus **nppiGetFilterGaussPyramidLayerDownBorderDstROI** (int nSrcROIWidth, int nSrcROIHeight, *NppiSize* *pDstSizeROI, *Npp32f* nRate)

Calculate destination image SizeROI width and height from source image ROI width and height and downsampling rate.

It is highly recommended that this function be use to determine the destination image ROI for consistent results.

Parameters

- ▶ **nSrcROIWidth** – The desired source image ROI width, must be $\leq$ oSrc-Size.width.
- ▶ **nSrcROIHeight** – The desired source image ROI height, must be $\leq$ oSrc-Size.height.
- ▶ **pDstSizeROI** – Host memory pointer to the destination image roi_specification.
- ▶ **nRate** – The downsampling or upsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be $> 1.0F$ and $\leq 10.0F$.

1.10.5.17 Image Filter Gauss Pyramid Layer Up Border

1.10.5.17.1 FilterGaussPyramidLayerUpBorder

Filters the image using a separable Gaussian filter kernel with user supplied floating point coefficients with upsampling and border control.

If the upsampling rate is equivalent to an integer value then unnecessary source pixels are just skipped. If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_MIRROR and NPP_BORDER_REPLICATE border type operations are supported.

1.10.5.17.1.1 Common parameters for nppiFilterGaussPyramidLayerUpBorder functions:

param pSrc

Source-Image Pointer.

param nSrcStep

Source-Image Line Step.

param oSrcSize

Source image width and height in pixels relative to pSrc.

param oSrcOffset

The pixel offset that pSrc points to relative to the origin of the source image.

param pDst

Destination-Image Pointer.

param nDstStep

Destination-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param nRate

The upsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be > 1.0F and <= 10.0F.

param nFilterTaps

The number of filter taps where $nFilterTaps = 2 * ((int)((float)ceil(radius) + 0.5F)) + 1$.

param pKernel

Pointer to an array of nFilterTaps kernel coefficients which sum to 1.0F.

param eBorderType

The border type operation to be applied at source image border boundaries.

param nppStreamCtx

Application Managed Stream Context.

Functions

NppStatus **nppiGetFilterGaussPyramidLayerUpBorderDstROI** (int nSrcROIWidth, int nSrcROIHeight, *NppiSize* *pDstSizeROIMin, *NppiSize* *pDstSizeROIMax, *Npp32f* nRate)

Calculate destination image minimum and maximum SizeROI width and height from source image ROI width and height and upsampling rate.

It is highly recommended that this function be use to determine the best destination image ROI for consistent results.

Parameters

- ▶ **nSrcROIWidth** – The desired source image ROI width, must be $\leq$ oSrc-Size.width.
- ▶ **nSrcROIHeight** – The desired source image ROI height, must be $\leq$ oSrc-Size.height.
- ▶ **pDstSizeROImin** – Host memory pointer to the minimum recommended destination image roi_specification.
- ▶ **pDstSizeROImax** – Host memory pointer to the maximum recommended destination image roi_specification.
- ▶ **nRate** – The upsampling rate to be used. For integer equivalent rates unnecessary source pixels are just skipped. For non-integer rates the source image is bilinear interpolated. nRate must be $> 1.0F$ and $\leq 10.0F$.

1.10.5.18 Image Filter Bilateral Gauss Border

1.10.5.18.1 FilterBilateralGaussBorder

Filters the image using a bilateral Gaussian filter kernel with border control.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

For this filter the anchor point is always the central element of the kernel. Coefficients of the bilateral filter kernel depend on their position in the kernel and on the value of some source image pixels overlayed by the filter kernel. Only source image pixels with both coordinates divisible by nDistance-BetweenSrcPixels are used in calculations.

The value of an output pixel d is

$$d = \frac{\sum_{h=-nRadius}^{nRadius} \sum_{w=-nRadius}^{nRadius} W1(h, w) \cdot W2(h, w) \cdot S(h, w)}{\sum_{h=-nRadius}^{nRadius} \sum_{w=-nRadius}^{nRadius} W1(h, w) \cdot W2(h, w)}$$

where h and w are the corresponding kernel width and height indexes, $S(h, w)$ is the value of the source image pixel overlayed by filter kernel position (h, w) , $W1(h, w)$ is $\text{func}(\text{nValSquareSigma}, (S(h, w) - S(0, 0)))$ where $S(0, 0)$ is the value of the source image pixel at the center of the kernel, $W2(h, w)$ is $\text{func}(\text{nPosSquareSigma}, \text{sqrt}(h^2 + w^2))$, and func is the following formula

$$\text{func}(S, I) = \exp\left(-\frac{I^2}{2.0F \cdot S^2}\right)$$

Supported border types:

- ▶ NPP_BORDER_REPLICATE — edge pixel is repeated (clamp)
- ▶ NPP_BORDER_MIRROR (4) — IPP mirrored / OpenCV BORDER_REFLECT_101: gfedcb|abcdefgh|gfedcba (edge NOT repeated)
- ▶ NPP_BORDER_MIRROR_REFL (5) — IPP mirrored with replication / OpenCV BORDER_REFLECT: fedcba|abcdefgh|hgfedcba (edge IS repeated)

1.10.5.25 Image Filter Unsharp Border

1.10.5.25.1 FilterUnsharpBorder

Filters the image using a unsharp-mask sharpening filter kernel with border control.

The algorithm involves the following steps: Smooth the original image with a Gaussian filter, with the width controlled by the `nRadius`. Subtract the smoothed image from the original to create a high-pass filtered image. Apply any clipping needed on the high-pass image, as controlled by the `nThreshold`. Add a certain percentage of the high-pass filtered image to the original image, with the percentage controlled by the `nWeight`. In pseudocode this algorithm can be written as: $\text{HighPass} = \text{Image} - \text{Gaussian}(\text{Image})$ $\text{Result} = \text{Image} + \text{nWeight} * \text{HighPass} * (|\text{HighPass}| \geq \text{nThreshold})$ where `nWeight` is the amount, `nThreshold` is the threshold, and `>=` indicates a Boolean operation, 1 if true, or 0 otherwise.

If any portion of the mask overlaps the source image boundary, the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the `NPP_BORDER_REPLICATE` border type operation is supported.

1.10.5.26 Image Filter Wiener Border

1.10.5.26.1 FilterWienerBorder

Noise removal filtering of an image using an adaptive Wiener filter with border control.

Pixels under the source mask are used to generate statistics about the local neighborhood which are then used to control the amount of adaptive noise filtering locally applied.

Note that if the noise value for a particular channel is set to 0.0f then the output for that channel will contain the square of the variance of local pixels within aMaskSize surrounding each pixel in oSizeROI. Note that is unlikely to be useful unless the pixel data type is floating point due to result clamping. Output from these cases can then be passed through an nppiMean function call using the same oSizeROI. The square root for that channel from the nppiMean call result can then be used as a noise value for a future call to this function if there is no known preexisting noise value.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.10.5.26.1.1 Common parameters for nppiFilterWienerBorder functions:

For each pixel in the source image the function estimates the local mean and variance in the neighborhood defined by oMaskSize relative to the primary source pixel located at oAnchor.x and oAnchor.y. Given an oMaskSize with width W and height H , the mean, variance, and destination pixel value will be computed per channel as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

$$Variance^2 = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i)^2 - Mean^2)$$

$$pDst(j, i) = Mean + \frac{(Variance^2 - NoiseVariance^2)}{Variance^2} \cdot (pSrc(j, i) - Mean)$$

1.10.5.27 Image Filter Gradient Vector Prewitt Border

1.10.5.27.1 GradientVectorPrewittBorder

RGB Color to Prewitt Gradient Vector conversion using user selected fixed mask size and gradient distance method. Functions support up to 4 optional single channel output gradient vectors, X (vertical), Y (horizontal), magnitude, and angle with user selectable distance methods. Output for a particular vector is disabled by supplying a NULL pointer for that vector. X and Y gradient vectors are in cartesian form in the destination data type.

Magnitude vectors are polar gradient form in the destination data type, angle is always in floating point polar gradient format. Only fixed mask sizes of 3x3 are supported. Only nppiNormL1 (sum) and nppiNormL2 (sqrt of sum of squares) distance methods are currently supported.

Currently only the NPP_BORDER_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

1.10.5.27.1.1 Common parameters for nppiFilterGradientVectorPrewittBorder functions:

The following fixed kernel mask is used for producing the pDstX (vertical) output image.

$$\begin{pmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{pmatrix}$$

The following fixed kernel mask is used for producing the pDstY (horizontal) output image.

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{pmatrix}$$

For the C1R versions of the function the pDstMag output image value for L1 normalization consists of the absolute value of the pDstX value plus the absolute value of the pDstY value at that particular image pixel location. For the C1R versions of the function the pDstMag output image value for L2 normalization consists of the square root of the pDstX value squared plus the pDstY value squared at that particular image pixel location. For the C1R versions of the function the pDstAngle output image value consists of the arctangent (atan2) of the pDstY value and the pDstX value at that particular image pixel location.

For the C3C1R versions of the function, regardless of the selected normalization method, the L2 normalization value is first determined for each of the pDstX and pDstY values for each source channel then the largest L2 normalization value (largest gradient) is used to select which of the 3 pDstX channel values are output to the pDstX image or pDstY channel values are output to the pDstY image. For the C3C1R versions of the function the pDstMag output image value for L1 normalization consists of the same technique used for the C1R version for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 pDstMag channel values to output to the pDstMag image. For the C3C1R versions of the function the pDstMag output image value for L2 normalization consists of just outputting the largest per source channel L2 normalization value to the pDstMag image. For the C3C1R versions of the function the pDstAngle output image value consists of the same technique used for the C1R version calculated for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 angle values to output to the pDstAngle image.

1.10.5.28 Image Filter Gradient Vector Scharr Border

1.10.5.28.1 GradientVectorScharrBorder

RGB Color to Scharr Gradient Vector conversion using user selected fixed mask size and gradient distance method. Functions support up to 4 optional single channel output gradient vectors, X (vertical), Y (horizontal), magnitude, and angle with user selectable distance methods. Output for a particular vector is disabled by supplying a NULL pointer for that vector. X and Y gradient vectors are in cartesian form in the destination data type.

Magnitude vectors are polar gradient form in the destination data type, angle is always in floating

point polar gradient format. Only fixed mask sizes of 3x3 are supported. Only nppiNormL1 (sum) and nppiNormL2 (sqrt of sum of squares) distance methods are currently supported.

Currently only the NPP_BORDER_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

1.10.5.28.1.1 Common parameters for nppiFilterGradientVectorScharrBorder functions:

The following fixed kernel mask is used for producing the pDstX (vertical) output image.

$$\begin{pmatrix} 3 & 0 & -3 \\ 10 & 0 & -10 \\ 3 & 0 & -3 \end{pmatrix}$$

The following fixed kernel mask is used for producing the pDstY (horizontal) output image.

$$\begin{pmatrix} 3 & 10 & 3 \\ 0 & 0 & 0 \\ -3 & -10 & -3 \end{pmatrix}$$

For the C1R versions of the function the pDstMag output image value for L1 normalization consists of the absolute value of the pDstX value plus the absolute value of the pDstY value at that particular image pixel location. For the C1R versions of the function the pDstMag output image value for L2 normalization consists of the square root of the pDstX value squared plus the pDstY value squared at that particular image pixel location. For the C1R versions of the function the pDstAngle output image value consists of the arctangent (atan2) of the pDstY value and the pDstX value at that particular image pixel location.

For the C3C1R versions of the function, regardless of the selected normalization method, the L2 normalization value is first determined for each of the pDstX and pDstY values for each source channel then the largest L2 normalization value (largest gradient) is used to select which of the 3 pDstX channel values are output to the pDstX image or pDstY channel values are output to the pDstY image. For the C3C1R versions of the function the pDstMag output image value for L1 normalization consists of the same technique used for the C1R version for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 pDstMag channel values to output to the pDstMag image. For the C3C1R versions of the function the pDstMag output image value for L2 normalization consists of just outputting the largest per source channel L2 normalization value to the pDstMag image. For the C3C1R versions of the function the pDstAngle output image value consists of the same technique used for the C1R version calculated for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 angle values to output to the pDstAngle image.

1.10.5.29 Image Filter Gradient Vector Sobel Border

1.10.5.29.1 GradientVectorSobelBorder

RGB Color to Sobel Gradient Vector conversion using user selected fixed mask size and gradient distance method. Functions support up to 4 optional single channel output gradient vectors, X (vertical), Y (horizontal), magnitude, and angle with user selectable distance methods. Output for a particular vector is disabled by supplying a NULL pointer for that vector. X and Y gradient vectors are in cartesian form in the destination data type.

Magnitude vectors are polar gradient form in the destination data type, angle is always in floating point polar gradient format. Only fixed mask sizes of 3x3 and 5x5 are supported. Only nppiNormL1 (sum) and nppiNormL2 (sqrt of sum of squares) distance methods are currently supported.

Currently only the NPP_BORDER_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

1.10.5.29.1.1 Common parameters for nppiFilterGradientVectorSobelBorder functions:

One of the following fixed kernel masks are used for producing the 3x3 or 5x5 pDstX (vertical) output image depending on selected mask size.

$$\begin{pmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{pmatrix}$$

$$\begin{pmatrix} -1 & -2 & 0 & 2 & 1 \\ -4 & -8 & 0 & 8 & 4 \\ -6 & -12 & 0 & 12 & 6 \\ -4 & -8 & 0 & 8 & 4 \\ -1 & -2 & 0 & 2 & 1 \end{pmatrix}$$

One of the following fixed kernel masks are used for producing the 3x3 or 5x5 pDstY (horizontal) output image depending on selected mask size.

$$\begin{pmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 4 & 6 & 4 & 1 \\ 2 & 8 & 12 & 8 & 2 \\ 0 & 0 & 0 & 0 & 0 \\ -2 & -8 & -12 & -8 & -2 \\ -1 & -4 & -6 & -4 & -1 \end{pmatrix}$$

For the C1R versions of the function the pDstMag output image value for L1 normalization consists of the absolute value of the pDstX value plus the absolute value of the pDstY value at that particular image pixel location. For the C1R versions of the function the pDstMag output image value for L2 normalization consists of the square root of the pDstX value squared plus the pDstY value squared at that particular image pixel location. For the C1R versions of the function the pDstAngle output image value consists of the arctangent (atan2) of the pDstY value and the pDstX value at that particular image pixel location.

For the C3C1R versions of the function, regardless of the selected normalization method, the L2 normalization value is first determined for each of the pDstX and pDstY values for each source channel then the largest L2 normalization value (largest gradient) is used to select which of the 3 pDstX channel values are output to the pDstX image or pDstY channel values are output to the pDstY image. For the C3C1R versions of the function the pDstMag output image value for L1 normalization consists of the same technique used for the C1R version for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 pDstMag channel values to output to the pDstMag image. For the C3C1R versions of the function the pDstMag output image value for L2 normalization consists of just outputting the largest per source channel L2 normalization value to the pDstMag image. For the C3C1R versions of the function the pDstAngle output image value consists of the same technique used for the C1R version calculated for each source image channel. Then the largest L2 normalization value is again used to select which of the 3 angle values to output to the pDstAngle image.

1.10.6. Computer Vision Filtering Functions

1.10.6.1 Computer Vision

The set of computer vision functions available in the library.

1.10.6.2 Image Filter Distance Transform

1.10.6.2.1 FilterDistanceTransform

Performs Exact Euclidean Distance Transform function using the Parallel Banding Algorithm (PBA+) defined by Tiow-Seng Tan, et al paper named “Parallel Banding Algorithm to Compute Exact Distance Transform with the GPU” published dated August 8, 2019.

Output for these functions is an optional 16-bit signed integer voronoi diagram (pairs of signed 16 bit integer x, y distance values) and/or an optional true euclidean distance transform image generated from the internal voronoi diagram in either unsigned 16-bit truncated integer format or 32-bit floating point format. Additional optional output can include an signed 16-bit integer Voronoi diagram containing site indices and/or a signed 16-bit integer Voronoi diagram containing relative Manhattan distances to the closest sites. Minimum and maximum image ROI widths and heights are 64 and 32767.

Note that an input image that does not contain at least one site pixel is considered to be an invalid image. If you suspect that your input image may be invalid you can call an NPP function like `nppi_CountInRange()` first to confirm that the image is valid before calling the distance transform function.

The `nMinSiteValue` and `nMaxSiteValue` parameters can be used to control which source image pixels are considered sites (traditionally 0) and non-sites (everything else).

Antialiased true distance transform, when available, is only available as double precision floating point (`Npp64f`) output data only and is enabled by setting the `pAntialiasingDeviceBuffer` pointer parameter to a non-NULL value.

The algorithm used for antialiasing is derived from the `edtaa4` version from “Anti-aliased Euclidean distance transform” by Stefan Gustavson et. al. published in 2009 and is used under the permissions specified below.

Derived from `edtaa4.c` - compute the Euclidean distance transform of an image, with more accurate handling of 1 pixel wide anti-aliased edges.

This is a MEX-file for MATLAB. MATLAB is a product of The MathWorks, Inc.

Code in “`edtaa4func.c`” originally by Stefan Gustavson 1994, implemented from a verbal description in the PhD dissertation of Ingemar Ragnemalm, dept of EE, Linköping University.

1 channel 32-bit floating point grayscale to optional 1 channel 16-bit signed integer euclidean distance voronoi diagram and 32-bit floating point transform with optional sub-pixel shifts.

For this particular version of the function acceptable input pixel intensities are less than or equal to 0.0f for those fully outside of connected pixel regions, intensities with fractional parts between 0.0f and 1.0f representing the percentage of connected pixel region sub-pixel coverage within a particular pixel (region contour), and intensities greater than or equal to 1.0f for pixels that are fully contained within closed connected pixel regions. This function executes in two passes, the first pass prioritizes pixels outside of closed regions, the second pass prioritizes pixels within closed regions. The two passes are then merged on output. The function assumes that fully covered pixels have centers located at sub-pixel locations of .5,.5 . In general, object exterior distances are output as negative numbers and object interior distances are output as positive numbers.

Parameters

- ▶ **pSrc** – *Source-Image Pointer*.

1.10.6.3 Image Filter Canny Border

1.10.6.3.1 FilterCannyBorder

Performs Canny edge detection on a single channel 8-bit grayscale image and outputs a single channel 8-bit image consisting of 0x00 and 0xFF values with 0xFF representing edge pixels.

The algorithm consists of three phases. The first phase generates two output images consisting of a single channel 16-bit signed image containing magnitude values and a single channel 32-bit floating point image containing the angular direction of those magnitude values. This phase is accomplished by calling the appropriate GradientVectorBorder filter function based on the filter type, filter mask size, and norm type requested. The next phase uses those magnitude and direction images to suppress non-maximum magnitude values which are lower than the values of either of its two nearest neighbors in the same direction as the test magnitude pixel in the 3x3 surrounding magnitude pixel neighborhood. This phase outputs a new magnitude image with non-maximum pixel values suppressed. Finally, in the third phase, the new magnitude image is passed through a hysteresis threshold filter that filters out any magnitude values that are not connected to another edge magnitude value. In this phase, any magnitude value above the high threshold value is automatically accepted, any magnitude value below the low threshold value is automatically rejected. For magnitude values that lie between the low and high threshold, values are only accepted if one of their two neighbors in the same direction in the 3x3 neighborhood around them lies above the low threshold value. In other words, if they are connected to an active edge. J. Canny recommends that the ratio of high to low threshold limit be in the range two or three to one, based on predicted signal-to-noise ratios. The final output of the third phase consists of a single channel 8-bit unsigned image of 0x00 and 0xFF values based on whether they are accepted or rejected during threshold testing.

Currently only the NPP_BORDER_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

1.10.6.4 Image Filter Harris Corners Border

1.10.6.4.1 FilterHarrisCornersBorder

Performs Harris Corner detection on a single channel 8-bit grayscale image and outputs a single channel 32-bit floating point image consisting the corner response at each pixel of the image.

The algorithm consists of two phases. The first phase generates the floating point product of XX, YY, and XY gradients at each pixel in the image. The type of gradient used is controlled by the eFilterType and eMaskSize parameters. The second phase averages those products over a window of either 3x3 or 5x5 pixels around the center pixel then generates the Harris corner response at that pixel which is output in the destination image. The Harris response value is determined as $H = ((XX * YY - XY * XY) - (nK * ((XX + YY) * (XX + YY)))) * nScale$.

Currently only the NPP_BORDER_REPLICATE border type operation is supported. Borderless output can be accomplished by using a larger source image than the destination and adjusting oSrcSize and oSrcOffset parameters accordingly.

1.10.6.5 Image Filter Hough Line

1.10.6.5.1 FilterHoughLine

Extracts Hough lines from a single channel 8-bit binarized (0, 255) source feature (canny edges, etc.) image.

Outputs a list of lines in point polar format representing the length (rho) and angle (theta) of each line from the origin of the normal to the line using the formula $\rho = x \cos(\theta) + y \sin(\theta)$. The level of discretization, nDelta, is specified as an input parameter. The performance and effectiveness of this function highly depends on this parameter with higher performance for larger numbers and more detailed results for lower numbers. Also, lines are not guaranteed to be added to the pDeviceLines list in the same order from one call to the next. However, all of the same lines will still be generated as long as nMaxLineCount is set large enough so that they all can fit in the list. To convert lines in point polar format back to cartesian lines use the following formula:

```

Npp32f nHough = ((sqrt(2.0F) * static_cast<Npp32f>(oSizeROI.height > oSizeROI.width ?
↳oSizeROI.height
                                                    :

int nCenterX = oSizeROI.width >> 1;
int nCenterY = oSizeROI.height >> 1;
Npp32f nThetaRad = static_cast<Npp32f>(deviceline.theta) * 0.0174532925199433F;

1.10.6.6 Image Filter Histogram Of Oriented Gradients Border

1.10.6.6.1 HistogramOfOrientedGradientsBorder

Performs Histogram Of Oriented Gradients operation on source image generating separate windows of Histogram Descriptors for each requested location.

This function implements the simplest form of functionality described by N. Dalal and B. Triggs. Histograms of Oriented Gradients for Human Detection. INRIA, 2005. It supports overlapped contrast normalized block histogram output with L2 normalization only, no threshold clipping, and no pre or post gaussian smoothing of input images or histogram output values. It supports both single channel grayscale source images and three channel color images. For color images, the color channel with the highest magnitude value is used as that pixel's magnitude. Output is row order only. Descriptors are output consecutively with no separation padding if multiple descriptor output is requested (one descriptor per source image location). For example, common HOG parameters are 9 histogram bins per 8 by 8 pixel cell, 2 by 2 cells per block, with a descriptor window size of 64 horizontal by 128 vertical pixels yielding 7 by 15 overlapping blocks (1 cell overlap in both horizontal and vertical directions). This results in 9 bins * 4 cells * 7 horizontal overlapping blocks * 15 vertical overlapping blocks or 3780 32-bit floating point output values (bins) per descriptor window.

The number of horizontal overlapping block histogram bins per descriptor window width is determined by $((\text{oHOGConfig.detectionWindowSize.width} / \text{oHOGConfig.histogramBlockSize}) * 2) - 1) * \text{oHOGConfig.nHistogramBins}$. The number of vertical overlapping block histograms per descriptor window height is determined by $((\text{oHOGConfig.detectionWindowSize.height} / \text{oHOGConfig.histogramBlockSize}) * 2) - 1)$. The offset of each descriptor window in the descriptors output buffer is therefore horizontal histogram bins per descriptor window width * vertical histograms per descriptor window height 32-bit floating point values relative to the previous descriptor window output.

The algorithm uses a 1D centered derivative mask of [-1, 0, +1] when generating input magnitude and angle gradients. Magnitudes are added to the two nearest histogram bins of oriented gradients between 0 and 180 degrees using a weighted linear interpolation of each magnitude value across the 2 nearest angular bin orientations. 2D overlapping blocks of histogram bins consisting of the bins from 2D arrangements of cells are then contrast normalized using L2 normalization and output to the corresponding histogram descriptor window for that particular window location in the window locations list.

Some restrictions include:

```
#define NPP_HOG_MAX_CELL_SIZE                (16)
#define NPP_HOG_MAX_BLOCK_SIZE              (64)
#define NPP_HOG_MAX_BINS_PER_CELL          (16)

#define NPP_HOG_MAX_OVERLAPPING_BLOCKS_PER_DESCRIPTOR (256)
#define NPP_HOG_MAX_DESCRIPTOR_LOCATIONS_PER_CALL (128)
```

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

Parameters

- ▶ **oHOGConfig** – Requested HOG configuration parameters structure.
- ▶ **hpLocations** – Host pointer to array of *NppiPoint* source pixel starting locations of requested descriptor windows. Important: hpLocations is a *host pointer*.
- ▶ **nLocations** – Number of *NppiPoint* in pLocations array.

NppStatus **nppiHistogramOfGradientsBorderGetDescriptorsSize**(const *NppiHOGConfig* oHOGConfig, int nLocations, int *hpDescriptorsSize)

Validates requested HOG configuration and calculates output window descriptors buffer size needed for the HistogramOfGradientsBorder function based on requested HOG configuration, and number of descriptor window locations, one descriptor window is output for each location.

Descriptor windows are located sequentially and contiguously in the descriptors buffer.

The number of horizontal overlapping block histogram bins per descriptor window width is determined by $((\text{oHOGConfig.detectionWindowSize.width} / \text{oHOGConfig.histogramBlockSize}) * 2) - 1$ * oHOGConfig.nHistogramBins. The number of vertical overlapping block histograms per descriptor window height is determined by $((\text{oHOGConfig.detectionWindowSize.height} / \text{oHOGConfig.histogramBlockSize}) * 2) - 1$. The offset of each descriptor window in the descriptors output buffer is therefore horizontal histogram bins per descriptor window width * vertical histograms per descriptor window height floating point values relative to the previous descriptor window output.

Parameters

- ▶ **nLocations** – Number of *NppiPoint* in pLocations array.

1.10.7. Image Filter Flood Fill

1.10.7.1 FloodFill

Flood fill a connected region of an image with a specified new value.

FloodFillGetBufferSize

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer.

The application allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

NppStatus **nppiFloodFillGetBufferSize**(*NppiSize* oSizeROI, int *hpBufferSize)

Calculate scratch buffer size needed for the FloodFill function based on destination image oSizeROI width and height.

Parameters

- ▶ **oSizeROI** – *Region-Of-Interest (ROI)*.
- ▶ **hpBufferSize** – Required buffer size in bytes.

1.10.7.2 Flood Fill

1.10.7.2.1 FloodFill

In place flood fill of a region of pixels connected to the pixel at the seed pixel location in an image with a new pixel value.

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the pConnectedRegion *NppiConnectedRegion* structure in host memory. The oBoundingBox x and y will be set to the left and top coordinates and width and height will be set to the right bottom coordinates of the bounding box relative to pSrcDst. Set pConnectedRegion to NULL if not required. Requesting pConnectedRegion information may slightly degrade performance.

Functions

NppStatus **nppiFloodFill_8u_C1IR_Ctx**(*Npp8u* *pSrcDst, int nSrcDstStep, *NppiPoint* oSeed, const *Npp8u* nNewValue, *NppiNorm* eNorm, *NppiSize* oSizeROI, *NppiConnectedRegion* *pConnectedRegion, *Npp8u* *pBuffer, *NppStreamContext* nppStreamCtx)

1.10.7.7 Flood Fill Gradient Boundary

1.10.7.7.1 FloodFillGradientBoundary

In place flood fill of a region of pixels connected to the pixel at the seed pixel location and with an original pixel value including seed - Min to seed + Max in an image with a new pixel value. Also fill boundary of filled region with a specified color.

In place flood fill of a region of pixels connected to the pixel at the seed pixel location in an image with a new pixel value.

Before calling any of the FloodFill functions the application first needs to call the FloodFillGetBufferSize function to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding FloodFill function.

Optionally the function can return connected region information for the filled region in the pConnectedRegion *NppiConnectedRegion* structure in host memory. The oBoundingBox x and y will be set to

the left and top coordinates and width and height will be set to the right bottom coordinates of the bounding box relative to pSrcDst. Set pConnectedRegion to NULL if not required. Requesting pConnectedRegion information may slightly degrade performance.

1.10.8. Label Markers

1.10.8.1 LabelMarkers

Generate image connected region label markers to be used for later image segmentation.

These functions have been deprecated. Use LabelMarkersUF functions instead.

LabelMarkersUFGetBufferSize

Before calling any of the LabelMarkersUF functions the application first needs to call the LabelMarkersUFGetBufferSize function to determine the amount of device memory to allocate as a working buffer.

The application allocated device memory is then passed as the pBuffer parameter to the corresponding LabelMarkersUF function.

NppStatus **nppiLabelMarkersUFGetBufferSize_32u_C1R**(*NppiSize* oSizeROI, int *hpBufferSize)

Calculate scratch buffer size needed 1 channel 32-bit unsigned integer LabelMarkersUF function based on destination image oSizeROI width and height.

Parameters

- ▶ **oSizeROI** – *Region-Of-Interest (ROI)*.
- ▶ **hpBufferSize** – Required buffer size in bytes.

1.10.8.2 Label MarkersUF

1.10.8.2.1 LabelMarkersUF

Generate image connected region label markers to be used for later image segmentation.

A connected region is any pixel region where all pixels in the region have the same pixel value. Note that marker label IDs generally increase in value from image left to right and top to bottom they are not generated in any particular order and there may be numeric gaps between sequential marker IDs. To limit the number of marker IDs generated the application should pass the image through a threshold filter before calling this function. Doing so however does not necessarily limit the maximum marker ID value generated by this function. Note that these functions currently only support image ROI sizes up to 4 gigapixels. Also note that while these functions support destination image pitches that are not exactly equal to oSizeROI.width * sizeof(Npp32u) it can avoid a cudaMemcpyAsync() call to copy the final result from the working buffer to the destination image if the pitch exactly equals oSizeROI.width * sizeof(Npp32u).

Before calling any of the LabelMarkersUF functions the application first needs to call the LabelMarkersUFGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding LabelMarkersUF function.

The algorithm used in this implementation is based on the one described in “An Optimized Union-Find Algorithm for Connected Components Labeling Using GPUs” by Jun Chen and others.

Note that the destination image in these functions must be allocated with cudaMalloc() and NOT cudaMallocPitch(). Also the pitch of the output image MUST be set to oSizeROI.width * sizeof(Npp32u).

1.10.8.3 Label MarkersUF Batch

1.10.8.3.1 LabelMarkersUFBatch

Generate image connected region label markers to be used for later image segmentation for a batched list of images.

A connected region is any pixel region where all pixels in the region have the same pixel value. Note that marker label IDs generally increase in value from image left to right and top to bottom they are not generated in any particular order and there may be numeric gaps between sequential marker IDs. To limit the number of marker IDs generated the application should pass the image through a threshold filter before calling this function. Doing so however does not necessarily limit the maximum marker ID value generated by this function. Note that these functions currently only support image ROI sizes up to 4 gigapixels. Also note that these functions work directly in the destination image so destination pitch MUST be equal to destination ROI.width * sizeof(Npp32u) and even if destination pitch is greater than that the output will be in that format. If this doesn't work for you use the single image version of these functions or *cudaMemcpy2D* can be called for each output image to restore the original pitch. Note that all source and destination images in the batch list must contain enough device memory to support the full ROI size. ROIs in descriptor lists are ignored in these functions.

The algorithm used in this implementation is based on the one described in “An Optimized Union-Find Algorithm for Connected Components Labeling Using GPUs” by Jun Chen and others.

Note that the destination images in these functions must be allocated with *cudaMalloc()* and NOT *cudaMallocPitch()*. Also the pitch of the output image MUST be set to *oSizeROI.width * sizeof(Npp32u)*.

Returns*Image Data Related Error Codes, ROI Related Error Codes***1.10.8.4 Label MarkersUF Batch Advanced****1.10.8.4.1 LabelMarkersUFBatchAdvanced**

Generate image connected region label markers to be used for later image segmentation for a batched list of images.

A connected region is any pixel region where all pixels in the region have the same pixel value. Note that marker label IDs generally increase in value from image left to right and top to bottom they are not generated in any particular order and there may be numeric gaps between sequential marker IDs. To limit the number of marker IDs generated the application should pass the image through a threshold filter before calling this function. Doing so however does not necessarily limit the maximum marker ID value generated by this function. Note that these functions currently only support image ROI sizes up to 4 gigapixels. Also note that these functions work directly in the destination image so destination pitch MUST be equal to destination ROI.width * sizeof(Npp32u) for each destination image in the list and even if the destination image pitch is greater than that of the output will be in that format. If this doesn't work for you use the single image version of these functions or cudaMemcpy2D can be called for each output image to restore the original pitch. Note that all source and destination images in the batch list must contain enough device memory to contain their specified ROI size.

The algorithm used in this implementation is based on the one described in “An Optimized Union-Find Algorithm for Connected Components Labeling Using GPUs” by Jun Chen and others.

Note that the destination images in these functions must be allocated with cudaMalloc() and NOT cudaMallocPitch(). Also the pitch of the output image MUST be set to oSizeROI.width * sizeof(Npp32u).

1.10.8.5 Image Filter Compress Marker Labels

Removes sparseness between marker label IDs output from LabelMarkers call.

CompressMarkerLabelsGetBufferSize

Before calling any of the CompressMarkerLabels functions the application first needs to call the corresponding CompressMarkerLabelsGetBufferSize function to determine the amount of device memory to allocate as a working buffer.

The application allocated device memory is then passed as the pBuffer parameter to the corresponding CompressMarkerLabels function.

NppStatus **nppiCompressMarkerLabelsGetBufferSize_32u_C1R**(int nStartingNumber, int *hpBufferSize)

Calculate scratch buffer size needed for 1 channel 32-bit unsigned integer CompressMarkerLabels function based on the number returned in pNumber from a previous nppiLabelMarkers call.

Note that this is the only function that supports the nppiCompressMarkerLabelsUF_32u function and that nStartingNumber MUST be ROI width * ROI height when used with that function.

Parameters

- ▶ **nStartingNumber** – The value returned from a previous call to the nppiLabelMarkers_32u function or ROI width * ROI height for images generated by the nppiLabelMarkersUF function and those values MUST match the values used those used in that call.
- ▶ **hpBufferSize** – Required buffer size in bytes.

CompressMarkerLabels

NOTE: The previous versions of these functions have been deprecated.

Only nppiCompressMarkerLabelsUF_32u works with output from nppiLabelMarkersUF functions.

NppStatus **nppiCompressMarkerLabelsUF_32u_C1IR_Ctx**(*Npp32u* *pSrcDst, int nSrcDstStep, *NppiSize* oSizeROI, int nStartingNumber, int *pNewNumber, *Npp8u* *pBuffer, *NppStreamContext* nppStreamCtx)

1 channel 32-bit unsigned integer in place connected region marker label renumbering for output from nppiLabelMarkersUF functions only with numbering sparseness elimination.

Note that the image in this function must be allocated with cudaMalloc() and NOT cudaMallocPitch(). Also the pitch MUST be set to oSizeROI.width * sizeof(Npp32u). And the image pointer and oSizeROI values MUST match those used when nppiLabelMarkersUF was called.

Parameters

- ▶ **pSrcDst** – *In-Place Image Pointer*.
- ▶ **nSrcDstStep** – *Source-Image Line Step*. NOTE THAT THIS VALUE MUST BE EQUAL TO oSizeROI.width * sizeof(Npp32u).
- ▶ **oSizeROI** – *Region-Of-Interest (ROI)*.

- ▶ **nStartingNumber** – MUST be ROI width * ROI height and MUST match ROI values used in the label markers generation function call.
- ▶ **pNewNumber** – Pointer to host memory integer value where the maximum renumbered marker label ID will be returned.
- ▶ **pBuffer** – Pointer to device memory scratch buffer at least as large as value returned by the corresponding CompressMarkerLabelsGetBufferSize call.
- ▶ **nppStreamCtx** – *Application Managed Stream Context.*

1 channel integer coordinate based contours image to marching squares bilinear interpolated coordinates contours image.

Note that ALL input and output data for the function MUST be in device memory except where noted otherwise. Also nFirstContourID and nLastContourID allow only a portion of the contour geometry lists in the image to be output.

Note that the geometry list for each contour will begin at pContoursGeometryList-sHost[pContoursPixelStartingOffsetHost[nContourID] * sizeof(NppiContourPixelGeometryInfo).

Note that to significantly improve performance by default a contour that contains more than 256K pixels will be bypassed when generating the output geometry list. The contour ID and number of contour pixels will be output in the contour list however. You can still get this function to output the geometry of this size contour however by calling the function with a starting contour ID of that contour ID and ending contour ID of that contour ID + 1. Note that doing so for contours approaching a million pixels can take many minutes. Also, due to the structure of some images contour ID 0 can contain ALL contours in the image so setting the starting contour ID to 1 can significantly increase output preprocessing performance.

Also note that the ordered contour geometry list is contained in the oContourOrderedGeometry-Location object within the *NppiContourPixelGeometryInfo* object for each contour pixel and that this location information is the only valid information in the object relevant to that ordered pixel.

Note that for a particular contour geometry pixel list the bounding box for that contour will be contained in the following elements of first pixel (pixel 0) of the corresponding contour pixel list.

```
pixel[0].oContourPrevPixelLocation.x will contain pCurMarkerLabelsInfo->
↳oMarkerLabelBoundingBox.x      upper left x
pixel[0].oContourPrevPixelLocation.y will contain pCurMarkerLabelsInfo->
↳oMarkerLabelBoundingBox.y      upper left y
pixel[0].oContourNextPixelLocation.x will contain pCurMarkerLabelsInfo->
↳oMarkerLabelBoundingBox.width  lower right x
pixel[0].oContourNextPixelLocation.y will contain pCurMarkerLabelsInfo->
↳oMarkerLabelBoundingBox.height lower right y
```

Note that while the bounding box is relatively accurate occasionally a few contour pixels may extend beyond the bounding box limits. Additionally, bounding box coordinates may vary slightly between runs on the same input due to the parallel reduction used internally; pixel counts (nMarkerLabelPixelCount) remain deterministic. If exact reproducible bounding boxes are required, derive them from the contour pixel geometry lists instead.

1.11. Image Geometry Transforms Functions

Routines manipulating an image geometry.

These functions can be found in the nppig library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

1.11.1. Geometric Transform API Specifics

This section covers some of the unique API features common to the geometric transform primitives.

1.11.2. Geometric Transforms and ROIs

Geometric transforms operate on source and destination ROIs. The way these ROIs affect the processing of pixels differs from other (non geometric) image-processing primitives: Only pixels in the intersection of the destination ROI and the transformed source ROI are being processed.

The typical processing proceeds as follows:

1. Transform the rectangular source ROI (given in source image coordinates) into the destination image space. This yields a quadrilateral.
2. Write only pixels in the intersection of the transformed source ROI and the destination ROI.

1.11.3. Pixel Interpolation

The majority of image geometry transform operation need to perform a resampling of the source image as source and destination pixels are not coincident.

NPP supports the following pixel interpolation modes (in order from fastest to slowest and lowest to highest quality):

- ▶ nearest neighbor
- ▶ linear interpolation
- ▶ cubic convolution
- ▶ supersampling
- ▶ interpolation using Lanczos window function

1.11.4. Resize Error Codes

The resize primitives return the following error codes:

- NPP_WRONG_INTERSECTION_ROI_ERROR indicates an error condition if srcROIrect has no intersection with the source image.
- NPP_RESIZE_NO_OPERATION_ERROR if either destination ROI width or height is less than 1 pixel.
- NPP_RESIZE_FACTOR_ERROR Indicates an error condition if either nXFactor or nYFactor is less than or equal to zero or in the case of NPPI_INTER_SUPER are not both downscaling.
- NPP_INTERPOLATION_ERROR if eInterpolation has an illegal value.
- NPP_SIZE_ERROR if source size width or height is less than 2 pixels.
- NPP_RECTANGLE_ERROR if either destination ROI width or height is less than 1 pixel.

1.11.5. ResizeSqrPixel

ResizeSqrPixel functions attempt to choose source pixels that would approximately represent the center of the destination pixels. It does so by using the following scaling formula to select source pixels for interpolation:

```
nAdjustedXFactor = 1.0 / nXFactor;
nAdjustedYFactor = 1.0 / nYFactor;
nAdjustedXShift = nXShift * nAdjustedXFactor + ((1.0 - nAdjustedXFactor) * 0.5);
nAdjustedYShift = nYShift * nAdjustedYFactor + ((1.0 - nAdjustedYFactor) * 0.5);
nSrcX = nAdjustedXFactor * nDstX - nAdjustedXShift;
nSrcY = nAdjustedYFactor * nDstY - nAdjustedYShift;
```

ResizeSqrPixel functions support the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_CUBIC2P_BSPLINE
NPPI_INTER_CUBIC2P_CATMULLROM
NPPI_INTER_CUBIC2P_B05C03
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

In the ResizeSqrPixel functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

GetResizeRect

Returns *NppiRect* which represents the offset and size of the destination rectangle that would be generated by resizing the source *NppiRect* by the requested scale factors and shifts.

NppStatus **nppiGetResizeRect**(*NppiRect* oSrcROI, *NppiRect* *pDstRect, double nXFactor, double nYFactor, double nXShift, double nYShift, int eInterpolation)

Parameters

- ▶ **oSrcROI** – Region of interest in the source image.
- ▶ **pDstRect** – User supplied host memory pointer to an *NppiRect* structure that will be filled in by this function with the region of interest in the destination image.
- ▶ **nXFactor** – Factor by which x dimension is changed.
- ▶ **nYFactor** – Factor by which y dimension is changed.
- ▶ **nXShift** – Source pixel shift in x-direction.
- ▶ **nYShift** – Source pixel shift in y-direction.

Returns

Image Data Related Error Codes, ROI Related Error Codes, Resize Error Codes

1.11.8. Resize

Resize functions use scale factor automatically determined by the width and height ratios of input and output *Region-Of-Interest (ROI)*.

This simplified function replaces the previous version which was deprecated in an earlier release. In this function the resize scale factor is automatically determined by the width and height ratios of oSrcRectROI and oDstRectROI. If either of those parameters intersect their respective image sizes then pixels outside the image size width and height will not be processed.

Resize supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_SUPER
NPPI_INTER_LANCZOS
```

The resize primitives return the following error codes: *Resize Error Codes*.

GetResizeTiledSourceOffset

Helper function that can be used when tiling a destination image with a source image using multiple Resize calls.

oSrcRectROI and oDstRectROI widths and heights should remain unmodified even if they will overlap source and destination image sizes. oDstRectROI offsets should be set to the destination offset of the new tile. Resize function processing will stop when source or destination image sizes are reached, any unavailable source image pixels beyond source image size will be border replicated. There is no particular association assumed between source and destination image locations. The values of oSrcRectROI.x and oSrcRectROI.y are ignored during this function call.

NppStatus nppiGetResizeTiledSourceOffset(*NppiRect* oSrcRectROI, *NppiRect* oDstRectROI, *NppiPoint* *pNewSrcRectOffset)

Parameters

- ▶ **oSrcRectROI** – Region of interest in the source image (may overlap source image size width and height).
- ▶ **oDstRectROI** – Region of interest in the destination image (may overlap destination image size width and height).

1.11.11. ResizeBatch

Above is the diagram of batch resize functions for variable ROIs. Figure shows the flexibility that the API can handle. The ROIs for source and destination images can be any rectangular width and height that reflects the needed resize factors, inside or beyond the image boundary.

ResizeBatch functions use scale factor automatically determined by the width and height ratios for each pair of input / output images in provided batches.

In this function as in nppiResize the resize scale factor is automatically determined by the width and height ratios of oSrcRectROI and oDstRectROI. If either of those parameters intersect their respective image sizes then pixels outside the image size width and height will not be processed. Details of the resize operation are described above in the Resize section. ResizeBatch generally takes the same

Diagram of batch resize functions for variable ROIs

parameter list as `Resize` except that there is a list of N instances of those parameters ($N > 1$) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of `oSrcRectROI` and `oDstRectROI` values are applied to each source image and destination image in the batch in the `nppiResizeBatch` version of the function while per image specific `oSrcRectROI` and `oDstRectROI` values can be used in the `nppiResizeBatch_Advanced` version of the function. Source and destination image sizes may vary but `oSmallestSrcSize` and `oSmallestDstSize` must be set to the smallest source and destination image sizes in the batch. The parameters in the *`NppiResizeBatchCXR`* structure represent the corresponding per-image `nppiResize` parameters for each image in the `nppiResizeBatch` functions and the *`NppImageDescriptor`* and *`NppiResizeBatchROI_Advanced`* structures represent the corresponding per-image `nppiResize` parameters for the `nppiResizeBatch_Advanced` functions. The *`NppiResizeBatchCXR`* or *`NppImageDescriptor`* and *`NppiResizeBatchROI_Advanced`* arrays must be in device memory.

`ResizeBatch` supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
NPPI_INTER_SUPER
```

The resize primitives return the following error codes: *`Resize Error Codes`*.

1.11.12. Remap

Routines providing remap functionality.

Remap supports the following interpolation modes:

NPPI_INTER_NN NPPI_INTER_LINEAR NPPI_INTER_CUBIC NPPI_INTER_CUBIC2P_BSPLINE
NPPI_INTER_CUBIC2P_CATMULLROM NPPI_INTER_CUBIC2P_BO5C03 NPPI_INTER_LANCZOS

Remap chooses source pixels using pixel coordinates explicitly supplied in two 2D device memory image arrays pointed to by the pXMap and pYMap pointers. The pXMap array contains the X coordinated and the pYMap array contains the Y coordinate of the corresponding source image pixel to use as input. These coordinates are in floating point format so fraction pixel positions can be used. The coordinates of the source pixel to sample are determined as follows:

$nSrcX = pXMap[nDstX, nDstY]$ $nSrcY = pYMap[nDstX, nDstY]$

In the Remap functions below source image clip checking is handled as follows:

If the source pixel fractional x and y coordinates are greater than or equal to oSizeROI.x and less than oSizeROI.x + oSizeROI.width and greater than or equal to oSizeROI.y and less than oSizeROI.y + oSizeROI.height then the source pixel is considered to be within the source image clip rectangle and the source image is sampled. Otherwise the source image is not sampled and a destination pixel is not written to the destination image.

1.11.13. Error Codes

The remap primitives return the following error codes:

- NPP_WRONG_INTERSECTION_ROI_ERROR indicates an error condition if srcROIRect has no intersection with the source image.
- NPP_INTERPOLATION_ERROR if eInterpolation has an illegal value.

1.11.19. Affine Transforms

1.11.19.1 Affine Transforms

1.11.19.1.1 Affine Transform Error Codes

- **NPP_RECTANGLE_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- **NPP_WRONG_INTERSECTION_ROI_ERROR** Indicates an error condition if oSrcROI has no intersection with the source image
- **NPP_INTERPOLATION_ERROR** Indicates an error condition if interpolation has an illegal value
- **NPP_COEFFICIENT_ERROR** Indicates an error condition if coefficient values are invalid
- **NPP_WRONG_INTERSECTION_QUAD_WARNING** Indicates a warning that no operation is performed if the transformed source ROI has no intersection with the destination ROI

1.11.19.2 Affine Transform Utility Functions

The set of affine transform utility functions.

Functions

NppStatus **nppiGetAffineTransform**(*NppiRect* oSrcROI, const double aQuad[4][2], double aCoeffs[2][3])

Computes affine transform coefficients based on source ROI and destination quadrilateral.

The function computes the coefficients of an affine transformation that maps the given source ROI (axis aligned rectangle with integer coordinates) to a quadrilateral in the destination image.

An affine transform in 2D is fully determined by the mapping of just three vertices. This function's API allows for passing a complete quadrilateral effectively making the problem overdetermined. What this means in practice is, that for certain quadrilaterals it is not possible to find an affine transform that would map all four corners of the source ROI to the four vertices of that quadrilateral.

The function circumvents this problem by only looking at the first three vertices of the destination image quadrilateral to determine the affine transformation's coefficients. If the destination quadrilateral is indeed one that cannot be mapped using an affine transformation the functions informs the user of this situation by returning a NPP_AFFINE_QUAD_INCORRECT_WARNING.

Parameters

- ▶ **oSrcROI** – The source ROI. This rectangle needs to be at least one pixel wide and high. If either width or height are less than one an NPP_RECTANGLE_ERROR is returned.
- ▶ **aQuad** – Host memory array containing the destination quadrilateral.
- ▶ **aCoeffs** – Host memory array containing the resulting affine transform coefficients.

Returns

Error codes:

- ▶ NPP_SIZE_ERROR Indicates an error condition if any image dimension has zero or negative value
- ▶ NPP_RECTANGLE_ERROR Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ NPP_COEFFICIENT_ERROR Indicates an error condition if coefficient values are invalid
- ▶ NPP_AFFINE_QUAD_INCORRECT_WARNING Indicates a warning when quad does not conform to the transform properties. Fourth vertex is ignored, internally computed coordinates are used instead

NppStatus **nppiGetAffineQuad**(*NppiRect* oSrcROI, double aQuad[4][2], const double aCoeffs[2][3])

Compute shape of transformed image.

This method computes the quadrilateral in the destination image that the source ROI is transformed into by the affine transformation expressed by the coefficients array (aCoeffs).

Parameters

- ▶ **oSrcROI** – The source ROI.
- ▶ **aQuad** – Host memory array that receives the resulting destination quadrangle.
- ▶ **aCoeffs** – Host memory array containing the affine transform coefficients.

Returns

Error codes:

- ▶ **NPP_SIZE_ERROR** Indicates an error condition if any image dimension has zero or negative value
- ▶ **NPP_RECTANGLE_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ **NPP_COEFFICIENT_ERROR** Indicates an error condition if coefficient values are invalid

NppStatus **nppiGetAffineBound**(*NppiRect* oSrcROI, double aBound[2][2], const double aCoeffs[2][3])

Compute bounding-box of transformed image.

The method effectively computes the bounding box (axis aligned rectangle) of the transformed source ROI (see *nppiGetAffineQuad()*).

Parameters

- ▶ **oSrcROI** – The source ROI.
- ▶ **aBound** – The resulting bounding box.
- ▶ **aCoeffs** – Host memory array containing the affine transform coefficients.

Returns

Error codes:

- ▶ **NPP_SIZE_ERROR** Indicates an error condition if any image dimension has zero or negative value
- ▶ **NPP_RECTANGLE_ERROR** Indicates an error condition if width or height of the intersection of the oSrcROI and source image is less than or equal to 1
- ▶ **NPP_COEFFICIENT_ERROR** Indicates an error condition if coefficient values are invalid

1.11.19.3 Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a 2×3 matrix (**C**). A pixel location (x, y) in the source image is mapped to (x', y') in the destination image. The destination coordinates are:

$$\begin{aligned} x' &= c_{00} x + c_{01} y + c_{02} \\ y' &= c_{10} x + c_{11} y + c_{12} \end{aligned}$$

The transform matrix is

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}$$

Affine transforms decompose into a linear part and a shift. The 2×2 matrix

$$L = \begin{bmatrix} c_{00} & c_{01} \\ c_{10} & c_{11} \end{bmatrix}$$

represents the linear transform, and the vector

$$v = \begin{bmatrix} c_{02} \\ c_{12} \end{bmatrix}$$

is the post-transform translation; i.e., after applying L , translate by v .

1.11.19.4 Affine Transform Batch

Details of the warp affine operation are described above in the WarpAffine section. WarpAffineBatch generally takes the same parameter list as WarpAffine except that there is a list of N instances of those parameters ($N > 1$) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The aTransformedCoeffs array is for internal use only and should not be directly initialized by the application. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of oSrcRectROI and oDstRectROI values are applied to each source image and destination image in the batch. Source and destination image sizes may vary but oSmallestSrcSize must be set to the smallest source and image size in the batch. The parameters in the *NppiWarpAffineBatchCXR* structure represent the corresponding per-image nppiWarpAffine parameters for each image in the batch. The *NppiWarpAffineBatchCXR* array must be in device memory. The nppiWarpAffineBatchInit function MUST be called AFTER the application has initialized the array of *NppiWarpAffineBatchCXR* structures and BEFORE calling any of the nppiWarpAffineBatch functions so that the aTransformedCoeffs array can be internally pre-initialized for each image in the batch. The batch size passed to nppiWarpAffineBatchInit must match the batch size passed to the corresponding warp affine batch function.

WarpAffineBatch supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
```

1.11.19.4.1 Codes

The warp affine primitives return the following error codes:

- NPP_RECTANGLE_ERROR if either destination ROI width or height is less than 1 pixel.
- NPP_INTERPOLATION_ERROR if eInterpolation has an illegal value.
- NPP_SIZE_ERROR if source size width or height is less than 2 pixels.

1.11.19.6 Backwards Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is given as a 2×3 matrix (C). A pixel location (x, y) in the source image is mapped to (x', y') in the destination image. The destination coordinates satisfy:

$$\begin{aligned} x &= c_{00} x' + c_{01} y' + c_{02} \\ y &= c_{10} x' + c_{11} y' + c_{12} \end{aligned}$$

with

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \end{bmatrix}.$$

In other words, given C , the source coordinates are transformed to the destination using the inverse matrix C^{-1} :

$$M = C^{-1} = \begin{bmatrix} m_{00} & m_{01} & m_{02} \\ m_{10} & m_{11} & m_{12} \end{bmatrix}$$

and the forward mapping is

$$\begin{aligned}x' &= m_{00} x + m_{01} y + m_{02} \\y' &= m_{10} x + m_{11} y + m_{12}\end{aligned}$$

1.11.19.7 Quad-Based Affine Transform

Transforms (warps) an image based on an affine transform.

The affine transform is computed such that it maps a quadrilateral in source image space to a quadrilateral in destination image space.

An affine transform is fully determined by the mapping of 3 discrete points. The following primitives compute an affine transformation matrix that maps the first three corners of the source quad are mapped to the first three vertices of the destination image quad. If the fourth vertices do not match the transform, an NPP_AFFINE_QUAD_INCORRECT_WARNING is returned by the primitive.

1.11.20.3 Perspective Transform Batch

Details of the warp perspective operation are described above in the WarpPerspective section. WarpPerspectiveBatch generally takes the same parameter list as WarpPerspective except that there is a list of N instances of those parameters (N > 1) and that list is passed in device memory. A convenient data structure is provided that allows for easy initialization of the parameter lists. The aTransformedCoeffs array is for internal use only and should not be directly initialized by the application. The only restriction on these functions is that there is one single source ROI rectangle and one single destination ROI rectangle which are applied respectively to each image in the batch. The primary purpose of this function is to provide improved performance for batches of smaller images as long as GPU resources are available. Therefore it is recommended that the function not be used for very large images as there may not be resources available for processing several large images simultaneously.

A single set of oSrcRectROI and oDstRectROI values are applied to each source image and destination image in the batch. Source and destination image sizes may vary but oSmallestSrcSize must be set to the smallest source and image size in the batch. The parameters in the *NppiWarpPerspectiveBatchCXR* structure represent the corresponding per-image nppiWarpPerspective parameters for each image in the batch. The *NppiWarpPerspectiveBatchCXR* array must be in device memory. The nppiWarpPerspectiveBatchInit function MUST be called AFTER the application has initialized the array of *NppiWarpPerspectiveBatchCXR* structures and BEFORE calling any of the nppiWarpPerspectiveBatch functions to so that the aTransformedCoeffs array can be internally pre-initialized for each image in the batch.

The batch size passed to `nppiWarpPerspectiveBatchInit` must match the batch size passed to the corresponding warp perspective batch function.

`WarpPerspectiveBatch` supports the following interpolation modes:

```
NPPI_INTER_NN
NPPI_INTER_LINEAR
NPPI_INTER_CUBIC
```

1.11.20.4 Backwards Perspective Transform

Transforms (warps) an image based on a perspective transform.

The perspective (projective) transform is given by a 3×3 matrix (C). A pixel location (x, y) in the source image maps to (x', y') in the destination as:

$$\begin{aligned} x' &= \frac{c_{00}x + c_{01}y + c_{02}}{c_{20}x + c_{21}y + c_{22}}, \\ y' &= \frac{c_{10}x + c_{11}y + c_{12}}{c_{20}x + c_{21}y + c_{22}}. \end{aligned}$$

where

$$C = \begin{bmatrix} c_{00} & c_{01} & c_{02} \\ c_{10} & c_{11} & c_{12} \\ c_{20} & c_{21} & c_{22} \end{bmatrix}.$$

Conversely, if $M = C^{-1}$, the destination coordinates (x', y') map back to source:

$$\begin{aligned} x &= \frac{m_{00}x' + m_{01}y' + m_{02}}{m_{20}x' + m_{21}y' + m_{22}}, \\ y &= \frac{m_{10}x' + m_{11}y' + m_{12}}{m_{20}x' + m_{21}y' + m_{22}}. \end{aligned}$$

1.11.20.4.1 Common parameters for nppiWarpPerspectiveBack packed pixel functions:

1.11.20.4.2 Common parameters for nppiWarpPerspectiveBack planar pixel functions:

Note: The denominators must be nonzero (valid homogeneous coordinate): $c_{20}x + c_{21}y + c_{22} \neq 0$ and $m_{20}x' + m_{21}y' + m_{22} \neq 0$; also $\det(C) \neq 0$.

32-bit floating point complex to 32-bit floating point squared magnitude.

Converts complex-number pixel image to single channel image computing the result pixels as the squared magnitude of the complex values.

The squared magnitude is an intermediate result of magnitude computation and can thus be computed faster than actual magnitude. If magnitudes are required for sorting/comparing only, using this function instead of `nppiMagnitude_32fc32f_C1R` can be a worthwhile performance optimization.

1.13.1.2 Image Dilate Border

1.13.1.2.1 Dilation with border control

Dilation computes the output pixel as the maximum pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the maximum search. For gray scale dilation the mask contains signed mask values which are added to the corresponding source image sample value before determining the maximum value after clamping.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

param pSrc

param nSrcStep

param oSrcSize

param oSrcOffset

1.13.2.2 Image Erode Border

1.13.2.2.1 Erosion with border control

Erosion computes the output pixel as the minimum pixel value of the pixels under the mask. Pixels whose corresponding mask values are zero do not participate in the minimum search. For gray scale erosion the mask contains signed mask values which are added to the corresponding source image sample value before determining the minimum value after clamping.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

param nSrcStep

param pMask

1.13.3.2 Image Morph Get Buffer Size

1.13.3.2.1 MorphGetBufferSize

Before calling any of the MorphCloseBorder, MorphOpenBorder, MorphTopHatBorder, MorphBlackHatBorder, or MorphGradientBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. 1.13.3.3 Image Morph Close Border

1.13.3.3.1 MorphCloseBorder

Dilation followed by Erosion with border control.

Morphological close computes the output pixel as the maximum pixel value of the pixels under the mask followed by a second pass using the result of the first pass as input which outputs the minimum pixel value of the pixels under the same mask. Pixels whose corresponding mask values are zero do not participate in the maximum or minimum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphCloseBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphCloseBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

param pSrc

param nSrcStep

Source-Image Line Step.

param oSrcSize

param oSrcOffset

param oSizeROI

param pMask

param oMaskSize

Width and Height mask array.

param oAnchor

param pBuffer

Pointer to device memory scratch buffer at least as large as value returned by the corresponding MorphGetBufferSize call.

param eBorderType

The border type operation to be applied at source image border boundaries.

param nppStreamCtx

Application Managed Stream Context.

Pixels whose corresponding mask values are zero do not participate in the minimum or maximum search.

If any portion of the mask overlaps the source image boundary the requested border type operation is applied to all mask pixels which fall outside of the source image. The mask is centered over the source image pixel being tested.

Before calling any of the MorphOpenBorder functions the application first needs to call the corresponding MorphGetBufferSize to determine the amount of device memory to allocate as a working buffer. The allocated device memory is then passed as the pBuffer parameter to the corresponding MorphOpenBorder function.

Use the oSrcOffset and oSrcSize parameters to control where the border control operation is applied to the source image ROI borders.

Currently only the NPP_BORDER_REPLICATE border type operation is supported.

1.14. Image Statistics Functions

Primitives for computing the statistical properties of an image.

Some statistical primitives also require scratch buffer during the computation. For details, please refer to *Scratch Buffer and Host Pointer*.

These functions can be found in the nppist library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

1.14.1. CommonGetBufferHostSizeParameters

Common parameters for nppiGetBufferHostSize functions include:

param oSizeROI

Region-Of-Interest (ROI).

param hpBufferSize

Required buffer size. Important: hpBufferSize is a *host pointer*. *Scratch Buffer and Host Pointer*.

param nppStreamCtx

Application Managed Stream Context.

return

NPP_NULL_POINTER_ERROR if hpBufferSize is 0 (NULL), *ROI Related Error Codes*.

1.14.2. Image Sum

1.14.2.1 Sum

Primitives for computing the sum of all the pixel values in an image.

Sum

Given an image $pSrc$ with width W and height H , the sum will be computed as

$$Sum = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$

All the results are stored in a 64-bit double precision format, except for two primitives `nppiSum_8u64s_C1R_Ctx` and `nppiSum_8u64s_C4R_Ctx`. The sum functions require additional scratch buffer for computations.

1.14.2.2 Common parameters for nppiSum functions include:

param pSrc

Source-Image Pointer.

param nSrcStep

Source-Image Line Step.

param oSizeROI

Region-Of-Interest (ROI).

param pDeviceBuffer

Pointer to the required device memory allocation, *Scratch Buffer and Host Pointer*. Use `nppiSumGetBufferHostSize_XX_XXX` to determine the minimum number of bytes required.

param pSum

Device memory pointer to the computed sum.

param nppStreamCtx

Application Managed Stream Context.

1.14.9. Image Mean StdDev

1.14.9.1 Mean_StdDev

Primitives for computing both the arithmetic mean and the standard deviation of an image.

Mean_StdDev

Given an image $pSrc$ with width W and height H , the mean and the standard deviation will be computed as

$$Mean = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} pSrc(j, i)$$
$$StdDev = \sqrt{\frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} (pSrc(j, i) - Mean)^2}$$

The Mean_StdDev primitives require additional scratch buffer for computations.

1.14.10. Image Norms

1.14.10.1 Image Norms

Primitives for computing the norms of an image, the norms of difference, and the relative errors of two images. Given an image *pSrc* with width *W* and height *H*,

1. The infinity norm (Norm_Inf) is defined as the largest absolute pixel value of the image.
2. The L1 norm (Norm_L1) is defined as the sum of the absolute pixel value of the image, i.e.,

$$Norm\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|$$

3. The L2 norm (Norm_L2) is defined as the square root of the sum of the squared absolute pixel value of the image, i.e.,

$$Norm\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc(j, i)|^2}$$

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The infinity norm of difference (NormDiff_Inf) is defined as the largest absolute difference between pixels of two images.
2. The L1 norm of difference (NormDiff_L1) is defined as the sum of the absolute difference between pixels of two images, i.e.,

$$NormDiff\_L1 = \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

3. The L2 norm of difference (NormDiff_L2) is defined as the squared root of the sum of the squared absolute difference between pixels of two images, i.e.,

$$NormDiff\_L2 = \sqrt{\sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|^2}$$

Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*,

1. The relative error for the infinity norm of difference (NormRel_Inf) is defined as NormDiff_Inf divided by the infinity norm of the second image, i.e.,

$$NormRel\_Inf = \frac{NormDiff\_Inf}{Norm\_Inf_{src2}}$$

2. The relative error for the L1 norm of difference (NormRel_L1) is defined as NormDiff_L1 divided by the L1 norm of the second image, i.e.,

$$NormRel\_L1 = \frac{NormDiff\_L1}{Norm\_L1_{src2}}$$

3. The relative error for the L2 norm of difference (NormRel_L2) is defined as NormDiff_L2 divided by the L2 norm of the second image, i.e.,

$$NormRel\_L2 = \frac{NormDiff\_L2}{Norm\_L2_{src2}}$$

The norm functions require the addition device scratch buffer for the computations.

1.14.18. Image Histogram Even

1.14.18.1 HistogramEven

Primitives for computing the histogram of an image with evenly distributed bins.

HistogramEven

The *nLowerLevel* (inclusive) and *nUpperLevel* (exclusive) define the boundaries of the range, which are evenly segmented into *nLevel* - 1 bins.

The computed histogram is stored in *pHist*. The levels are calculated by another primitive *nppevenLevelsHost_32s* and are stored in a host pointer *hpLevels*. The number of levels is also *nLevel* - 1. The histogram *pHist[k]* is defined as the total number of pixels that fall into the range: *hpLevels[k]* ≤ *pSrc(j, i)* < *hpLevels[k + 1]*. The functions require additional scratch buffer for computations.

1.14.20. Image Proximity

1.14.20.1 Image Proximity

Primitives for computing the proximity measure between a source image and a template image.

1.14.20.1.1 General Introduction

There are basically two approaches to compute the proximity measure for template matching, Euclidean distance and the cross correlation.

1.

Euclidean distance computes the sum of the squared distance (SSD) between the corresponding pixels of the source image and the template image. The smaller the distance is, the more similar the source image and the template image is around the pixel. The anchor of the template

image is used during the computations, which always lies in the geometric center of the image. Given a source image $pSrc$ ($W_s \times H_s$) and a template image $pTpl$ ($W_t \times H_t$), the Euclidean distance $D_{st}(c, r)$ between two images at pixel in row r and column c is computed as (s stands for source image and t for template image for short):

$$D_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]^2$$

2. Cross correlation computes the sum of the product between the corresponding pixels of the source image and the template image. The cross correlation $R_{st}(c, r)$ is calculated as:

$$R_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) \cdot pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2})]$$

The larger the cross correlation value is, the more similar the source image and the template image is around the pixel.

3. The cross correlation $R_{st}(c, r)$ is affected by the brightness of the images which may vary due to the lighting and exposure conditions. Therefore, NPP computes the cross correlation coefficient to circumvent this dependence. This is typically done at every step by subtracting the mean from every pixel value, i.e.,

$$\tilde{R}_{st}(c, r) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t] \cdot [pSrc(j + c - \frac{H_t}{2}, i + r - \frac{W_t}{2}) - Mean_s]$$

NPP computes the normalized values of Euclidean distance, cross correlation and the cross correlation coefficient.

1. The normalized Euclidean distance $\sigma_{st}(c, r)$ is defined as:

$$\sigma_{st}(c, r) = \frac{D_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

2. The normalized cross correlation $\rho_{st}(c, r)$ is defined as:

$$\rho_{st}(c, r) = \frac{R_{st}(c, r)}{\sqrt{R_{ss}(c, r) \cdot R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The $R_{ss}(c, r)$ and $R_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$ denote the auto correlation of the source image and the template image individually. They are defined as:

$$R_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} pSrc(j, i)$$

$$R_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} pTpl(j, i)$$

3. Similarly, the normalized cross correlation coefficient $\gamma_{st}(c, r)$ is calculated as:

$$\gamma_{st}(c, r) = \frac{\tilde{R}_{st}(c, r)}{\sqrt{\tilde{R}_{ss}(c, r) \cdot \tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})}}$$

The $\tilde{R}_{ss}(c, r)$ and $\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2})$ are defined as:

$$\tilde{R}_{ss}(c, r) = \sum_{j=c-\frac{H_t}{2}}^{c+\frac{H_t}{2}} \sum_{i=r-\frac{W_t}{2}}^{r+\frac{W_t}{2}} [pSrc(j, i) - Mean_s]$$

$$\tilde{R}_{tt}(\frac{H_t}{2}, \frac{W_t}{2}) = \sum_{j=0}^{H_t-1} \sum_{i=0}^{W_t-1} [pTpl(j, i) - Mean_t]$$

where $Mean_t$ is the template mean minus the mean of the image in the region just under the template.

1.14.20.1.2 Categorizations

The Euclidean distance and the cross correlation are categorized into three types, full, same, and valid.

1. Full mode indicates that the anchor of the template image starts from the outside of the source image, assuming the out-of-boundary pixels are zero-padded. The size of the destination image is $(W_s + W_t - 1) \times (H_s + H_t - 1)$.
2. Same mode means that the anchor of the template image starts from the top left pixel of the source image. All the out-of-boundary pixels are also zero-padded. The size of the destination image is the same as the source one, i.e., $W_s \times H_s$.
3. Valid mode indicates that there are no out-of-boundary readings from the source image. The anchor of the template image starts from the inside of the source image. The size of the destination image is $(W_s - W_t + 1) \times (H_s - H_t + 1)$.

1.14.29. Image Cross Correlation Same Norm Level

1.14.29.1 CrossCorrSame_NormLevel

Primitives for computing the normalized cross correlation coefficient between two images with same mode.

CrossCorrSame_NormLevel

The functions compute the $\gamma_{st}(c, r)$ in *General Introduction* with same mode (see *Categorizations*).

The functions require additional scratch buffer for computations.

Note: For maximum performance oSrcRoiSize.width MUST be an integer multiple of 4.

1.14.32. Image Cross Correlation Same Norm Level Advanced

1.14.32.1 CrossCorrSame_NormLevelAdvanced

Primitives for computing the normalized cross correlation coefficient between two images with same mode with large image template sizes.

CrossCorrSame_NormLevelAdvanced

The functions compute the $\gamma_{st}(c, r)$ in *General Introduction* with same mode (see *Categorizations*).

The functions require an additional scratch buffer and advanced scratch buffer for computations.

Note: For maximum performance oSrcRoiSize.width MUST be an integer multiple of 4.

Primitives for computing the normalized cross correlation coefficient between two images with valid mode with large template sizes.

CrossCorrValid_NormLevelAdvanced

The functions compute the $\gamma_{st}(c, r)$ in *General Introduction* with valid mode (see *Categorizations*).

The functions require an additional scratch buffer and advanced scratch buffer for computations.

Note: For maximum performance oSrcRoiSize.width - oTplRoiSize + 1 MUST be an integer multiple of 4.

1.14.34. Image Quality Index

1.14.34.1 Image Quality Index

Primitives for computing the image quality index of two images.

QualityIndex

Given two images M and N (both $W \times H$), the mathematical formula to calculate the image quality index Q between them is expressed as:

$$Q = \frac{4\sigma_{MN}\tilde{M}\tilde{N}}{[(\tilde{M}^2) + (\tilde{N}^2)][(\sigma_M)^2 + (\sigma_N)^2]}$$

where

$$\tilde{M} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} M(j, i)$$

$$\tilde{N} = \frac{1}{W \cdot H} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} N(j, i)$$

$$\sigma_M = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}]^2}$$

$$\sigma_N = \sqrt{\frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [N(j, i) - \tilde{N}]^2}$$

$$\sigma_{MN} = \frac{1}{W \cdot H - 1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} [M(j, i) - \tilde{M}][N(j, i) - \tilde{N}]$$

1.14.36. Image Average Error

1.14.36.1 AverageError

Primitives for computing the average error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the average error is defined as:

$$AverageError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} |pSrc1(j, i) - pSrc2(j, i)|$$

where *N* stands for the number of channels. If the image is in complex format, the absolute value is used for computation.

1.14.37. Image Maximum Relative Error

1.14.37.1 MaximumRelativeError

Primitives for computing the maximum relative error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum relative error is defined as:

$$\text{MaximumRelativeError} = \max \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

If the image is in complex format, the absolute value is used for computation. For multiple channels, the maximum relative error of all the channels is returned.

1.14.38. Image Average Relative Error

1.14.38.1 AverageRelativeError

Primitives for computing the average relative error between two images. Given two images *pSrc1* and *pSrc2* both with width *W* and height *H*, the maximum relative error is defined as:

$$AverageRelativeError = \frac{1}{W \cdot H \cdot N} \sum_{n=0}^{N-1} \sum_{j=0}^{H-1} \sum_{i=0}^{W-1} \frac{|pSrc1(j, i) - pSrc2(j, i)|}{\max(|pSrc1(j, i)|, |pSrc2(j, i)|)}$$

where *N* is the number of channels. If the image is in complex format, the absolute value is used for computation.

1.15.2. Image Comparison Operations

1.15.2.1 Comparison Operations

Compare the pixels of two images or one image and a constant value and create a binary result image. In case of multi-channel image types, the condition must be fulfilled for all channels, otherwise the comparison is considered false. The “binary” result image is of type 8u_C1. False is represented by 0, true by NPP_MAX_8U.

1.16. Image Memory Management Functions

Routines for allocating and deallocating pitched image storage.

These methods are provided for convenience. They allocate memory that may contain additional padding bytes at the end of each line of pixels. Though padding is not necessary for any of the NPP image-processing primitives to work correctly, its absence may cause severe performance degradation compared to properly padded images.

These functions can be found in the nppisu library. Linking to only the sub-libraries that you use can significantly save link time, application load time, and CUDA runtime startup time when using dynamic libraries.

Image Memory Allocation

ImageAllocator methods for 2D arrays of data.

The allocators have width and height parameters to specify the size of the image data being allocated. They return a pointer to the newly created memory and return the numbers of bytes between successive lines.

If the memory allocation failed due to lack of free device memory or device memory fragmentation the routine returns 0.

All allocators return memory with line strides that are beneficial for performance. It is not mandatory to use these allocators. Any valid CUDA device-memory pointers can be used by the NPP primitives and there are no restrictions on line strides.

1.21.15. Signal Maximum Relative Error

1.21.15.1 MaximumRelativeError

Primitives for computing the MaximumRelative error between two signals. Given two signals $pSrc1$ and $pSrc2$ both with length N , the maximum relative error is defined as

If the signal is in complex format, the absolute value of the complex number is used.

1.21.16. Signal Average Relative Error

1.21.16.1 AverageRelativeError

Primitives for computing the AverageRelative error between two signals. Given two signals *pSrc1* and *pSrc2* both with length *N*, the average relative error is defined as

If the signal is in complex format, the absolute value of the complex number is used.

1.22. Signal Memory Management Functions

Functions that provide memory management functionality like malloc and free.

1.22.1. Malloc

Signal-allocator methods for allocating 1D arrays of data in device memory. All allocators have size parameters to specify the size of the signal (1D array) being allocated.

The allocator methods return a pointer to the newly allocated memory of appropriate type. If device-memory allocation is not possible due to resource constraints the allocators return 0 (i.e. NULL pointer).

All signal allocators allocate memory aligned such that it is beneficial to the performance of the majority of the signal-processing primitives. It is no mandatory however to use these allocators. Any valid CUDA device-memory pointers can be passed to NPP primitives.

Functions

Npp8u ***nppsMalloc_8u**(size_t nSize)

Parameters

- **nSize** – Number of unsigned chars in the new signal.
