Chapter 1.
INTRODUCTION

The cuSolver library is a high-level package based on the cuBLAS and cuSPARSE libraries. It consists of two modules corresponding to two sets of API:

1. The cuSolver API on a single GPU
2. The cuSolverMG API on a single node multiGPU

Each of which can be used independently or in concert with other toolkit libraries. To simplify the notation, cuSolver denotes single GPU API and cuSolverMg denotes multiGPU API.

The intent of cuSolver is to provide useful LAPACK-like features, such as common matrix factorization and triangular solve routines for dense matrices, a sparse least-squares solver and an eigenvalue solver. In addition cuSolver provides a new refactorization library useful for solving sequences of matrices with a shared sparsity pattern.

cuSolver combines three separate components under a single umbrella. The first part of cuSolver is called cuSolverDN, and deals with dense matrix factorization and solve routines such as LU, QR, SVD and LDLT, as well as useful utilities such as matrix and vector permutations.

Next, cuSolverSP provides a new set of sparse routines based on a sparse QR factorization. Not all matrices have a good sparsity pattern for parallelism in factorization, so the cuSolverSP library also provides a CPU path to handle those sequential-like matrices. For those matrices with abundant parallelism, the GPU path will deliver higher performance. The library is designed to be called from C and C++.

The final part is cuSolverRF, a sparse re-factorization package that can provide very good performance when solving a sequence of matrices where only the coefficients are changed but the sparsity pattern remains the same.

The GPU path of the cuSolver library assumes data is already in the device memory. It is the responsibility of the developer to allocate memory and to copy data between GPU memory and CPU memory using standard CUDA runtime API routines, such as cudaMemcpy(), cudaMemcpyAsync().
cuSolverMg is GPU-accelerated ScaLAPACK. By now, cuSolverMg supports 1-D column block cyclic layout and provides symmetric eigenvalue solver.

The cuSolver library requires hardware with a CUDA compute capability (CC) of at least 2.0 or higher. Please see the CUDA C++ Programming Guide for a list of the compute capabilities corresponding to all NVIDIA GPUs.

1.1. cuSolverDN: Dense LAPACK

The cuSolverDN library was designed to solve dense linear systems of the form

\[ Ax = b \]

where the coefficient matrix \( A \in \mathbb{R}^{m \times n} \), right-hand-side vector \( b \in \mathbb{R}^n \) and solution vector \( x \in \mathbb{R}^n \).

The cuSolverDN library provides QR factorization and LU with partial pivoting to handle a general matrix \( A \), which may be non-symmetric. Cholesky factorization is also provided for symmetric/Hermitian matrices. For symmetric indefinite matrices, we provide Bunch-Kaufman (LDL) factorization.

The cuSolverDN library also provides a helpful bidiagonalization routine and singular value decomposition (SVD).

The cuSolverDN library targets computationally-intensive and popular routines in LAPACK, and provides an API compatible with LAPACK. The user can accelerate these time-consuming routines with cuSolverDN and keep others in LAPACK without a major change to existing code.

1.2. cuSolverSP: Sparse LAPACK

The cuSolverSP library was mainly designed to solve sparse linear system

\[ Ax = b \]

and the least-squares problem

\[ x = \arg \min \| Ax - b \| \]

where sparse matrix \( A \in \mathbb{R}^{m \times n} \), right-hand-side vector \( b \in \mathbb{R}^m \) and solution vector \( x \in \mathbb{R}^n \).

For a linear system, we require \( m = n \).

The core algorithm is based on sparse QR factorization. The matrix \( A \) is accepted in CSR format. If matrix \( A \) is symmetric/Hermitian, the user has to provide a full matrix, ie fill missing lower or upper part.

If matrix \( A \) is symmetric positive definite and the user only needs to solve \( Ax = b \), Cholesky factorization can work and the user only needs to provide the lower triangular part of \( A \).
On top of the linear and least-squares solvers, the cuSolverSP library provides a simple
eigenvalue solver based on shift-inverse power method, and a function to count the
number of eigenvalues contained in a box in the complex plane.

1.3. cuSolverRF: Refactorization

The cuSolverRF library was designed to accelerate solution of sets of linear systems by
fast re-factorization when given new coefficients in the same sparsity pattern

$$A_i x_i = f_i$$

where a sequence of coefficient matrices $A_i \in \mathbb{R}^{m \times n}$, right-hand-sides $f_i \in \mathbb{R}^n$ and solutions $x_i \in \mathbb{R}^n$ are given for $i=1, \ldots, k$.

The cuSolverRF library is applicable when the sparsity pattern of the coefficient matrices
$A_i$ as well as the reordering to minimize fill-in and the pivoting used during the LU
factorization remain the same across these linear systems. In that case, the first linear
system ($i=1$) requires a full LU factorization, while the subsequent linear systems
($i=2, \ldots, k$) require only the LU re-factorization. The later can be performed using the
cuSolverRF library.

Notice that because the sparsity pattern of the coefficient matrices, the reordering and
pivoting remain the same, the sparsity pattern of the resulting triangular factors
and also remains the same. Therefore, the real difference between the full LU factorization
and LU re-factorization is that the required memory is known ahead of time.

1.4. Naming Conventions

The cuSolverDN library provides two different APIs; legacy and generic.

The functions in the legacy API are available for data types float, double, cuComplex,
and cuDoubleComplex. The naming convention for the legacy API is as follows:

```
cusolverDn<t><operation>
```

where $<t>$ can be S, D, C, Z, or X, corresponding to the data types float, double,
cuComplex, cuDoubleComplex, and the generic type, respectively. $<operation>$ can
be Cholesky factorization (potrf), LU with partial pivoting (getrf), QR factorization
(geqrf) and Bunch-Kaufman factorization (sytrf).

The functions in the generic API provide a single entry point for each routine and
support for 64-bit integers to define matrix and vector dimensions. The naming
convention for the generic API is data-agnostic and is as follows:

```
cusolverDn<operation>
```

where $<operation>$ can be Cholesky factorization (potrf), LU with partial pivoting
(getrf) and QR factorization (geqrf).
The cuSolverSP library functions are available for data types \texttt{float}, \texttt{double}, \texttt{cuComplex}, and \texttt{cuDoubleComplex}. The naming convention is as follows:

\begin{verbatim}
cusolverSp[Host]<t>[<matrix data format>]<operation>[<output matrix data format>]<based on>
\end{verbatim}

where \texttt{cusolverSp} is the GPU path and \texttt{cusolverSpHost} is the corresponding CPU path. \texttt{<t>} can be \texttt{S}, \texttt{D}, \texttt{C}, \texttt{Z}, or \texttt{X}, corresponding to the data types \texttt{float}, \texttt{double}, \texttt{cuComplex}, \texttt{cuDoubleComplex}, and the generic type, respectively.

The \texttt{<matrix data format>} is \texttt{csr}, compressed sparse row format.

The \texttt{<operation>} can be \texttt{ls}, \texttt{lsq}, \texttt{eig}, \texttt{eigs}, corresponding to linear solver, least-square solver, eigenvalue solver and number of eigenvalues in a box, respectively.

The \texttt{<output matrix data format>} can be \texttt{v} or \texttt{m}, corresponding to a vector or a matrix.

\texttt{<based on>} describes which algorithm is used. For example, \texttt{qr} (sparse QR factorization) is used in linear solver and least-square solver.

All of the functions have the return type \texttt{cusolverStatus_t} and are explained in more detail in the chapters that follow.

The cuSolverRF library routines are available for data type \texttt{double}. Most of the routines follow the naming convention:

\begin{verbatim}
cusolverRf_<operation>[[Host]](...)
\end{verbatim}
where the trailing optional Host qualifier indicates the data is accessed on the host versus on the device, which is the default. The `<operation>` can be Setup, Analyze, Refactor, Solve, ResetValues, AccessBundledFactors and ExtractSplitFactors.

Finally, the return type of the cuSolverRF library routines is `cusolverStatus_t`.

### 1.5. Asynchronous Execution

The cuSolver library functions prefer to keep asynchronous execution as much as possible. Developers can always use the `cudaDeviceSynchronize()` function to ensure that the execution of a particular cuSolver library routine has completed.

A developer can also use the `cudaMemcpy()` routine to copy data from the device to the host and vice versa, using the `cudaMemcpyDeviceToHost` and `cudaMemcpyHostToDevice` parameters, respectively. In this case there is no need to add a call to `cudaDeviceSynchronize()` because the call to `cudaMemcpy()` with the above parameters is blocking and completes only when the results are ready on the host.

### 1.6. Library Property

The `libraryPropertyType` data type is an enumeration of library property types. (ie. CUDA version X.Y.Z would yield `MAJOR_VERSION=X, MINOR_VERSION=Y, PATCH_LEVEL=Z`)

```c
typedef enum libraryPropertyType_t
{
    MAJOR_VERSION,
    MINOR_VERSION,
    PATCH_LEVEL
} libraryPropertyType;
```

The following code can show the version of cusolver library.

```c
int major=-1,minor=-1,patch=-1;
cusolverGetProperty(MAJOR_VERSION, &major);
cusolverGetProperty(MINOR_VERSION, &minor);
cusolverGetProperty(PATCH_LEVEL, &patch);
printf("CUSOLVER Version (Major,Minor,PatchLevel): %d.%d.%d\n", major,minor,patch);
```

### 1.7. high precision package

The `cusolver` library uses high precision for iterative refinement when necessary.
Chapter 2.
USING THE CUSOLVER API

2.1. General description

This chapter describes how to use the cuSolver library API. It is not a reference for the cuSolver API data types and functions; that is provided in subsequent chapters.

2.1.1. Thread Safety

The library is thread-safe, and its functions can be called from multiple host threads.

2.1.2. Scalar Parameters

In the cuSolver API, the scalar parameters can be passed by reference on the host.

2.1.3. Parallelism with Streams

If the application performs several small independent computations, or if it makes data transfers in parallel with the computation, then CUDA streams can be used to overlap these tasks.

The application can conceptually associate a stream with each task. To achieve the overlap of computation between the tasks, the developer should:

1. Create CUDA streams using the function `cudaStreamCreate()`, and
2. Set the stream to be used by each individual cuSolver library routine by calling, for example, `cusolverDnSetStream()`, just prior to calling the actual cuSolverDN routine.

The computations performed in separate streams would then be overlapped automatically on the GPU, when possible. This approach is especially useful when the computation performed by a single task is relatively small, and is not enough to fill the GPU with work, or when there is a data transfer that can be performed in parallel with the computation.
2.1.4. Link Third-party LAPACK Library

Starting with CUDA 10.1 update 2, NVIDIA LAPACK library `liblapack_static.a` is a subset of LAPACK and only contains GPU accelerated `stedc` and `bdsqr`. The user has to link `libcusolver_static.a` with `liblapack_static.a` in order to build the application successfully. Prior to CUDA 10.1 update 2, the user can replace `liblapack_static.a` with a third-party LAPACK library, for example, MKL. In CUDA 10.1 update 2, the third-party LAPACK library no longer affects the behavior of cusolver library, neither functionality nor performance. Furthermore the user cannot use `liblapack_static.a` as a standalone LAPACK library because it is only a subset of LAPACK.

The `liblapack_static.a` library, which is the binary of CLAPACK-3.2.1, is a new feature of CUDA 10.0.

- If you use `libcusolver_static.a`, then you must link with `liblapack_static.a` explicitly, otherwise the linker will report missing symbols. No conflict of symbols between `liblapack_static.a` and other third-party LAPACK library, you are free to link the latter to your application.
- The `liblapack_static.a` is built inside `libcusolver.so`. Hence, if you use `libcusolver.so`, then you don’t need to specify a LAPACK library. The `libcusolver.so` will not pick up any routines from the third-party LAPACK library even you link the application with it.

2.1.5. convention of info

Each LAPACK routine returns an `info` which indicates the position of invalid parameter. If `info = -i`, then i-th parameter is invalid. To be consistent with base-1 in LAPACK, cusolver does not report invalid handle into `info`. Instead, cusolver returns `CUSOLVER_STATUS_NOT_INITIALIZED` for invalid handle.

2.1.6. usage of _bufferSize

There is no cudaMalloc inside cuSolver library, the user must allocate the device workspace explicitly. The routine `xyz_bufferSize` is to query the size of workspace of the routine `xyz`, for example `xyz = potrf`. To make the API simple, `xyz_bufferSize` follows almost the same signature of `xyz` even it only depends on some parameters, for example, device pointer is not used to decide the size of workspace. In most cases, `xyz_bufferSize` is called in the beginning before actual device data (pointing by a device pointer) is prepared or before the device pointer is allocated. In such case, the user can pass null pointer to `xyz_bufferSize` without breaking the functionality.
2.2. cuSolver Types Reference

2.2.1. cuSolverDN Types

The float, double, cuComplex, and cuDoubleComplex data types are supported. The first two are standard C data types, while the last two are exported from cuComplex.h. In addition, cuSolverDN uses some familiar types from cuBlas.

2.2.1.1. cuSolverDNHandle_t

This is a pointer type to an opaque cuSolverDN context, which the user must initialize by calling cusolverDnCreate() prior to calling any other library function. An un-initialized Handle object will lead to unexpected behavior, including crashes of cuSolverDN. The handle created and returned by cusolverDnCreate() must be passed to every cuSolverDN function.

2.2.1.2. cublasFillMode_t

The type indicates which part (lower or upper) of the dense matrix was filled and consequently should be used by the function. Its values correspond to Fortran characters ‘L’ or ‘l’ (lower) and ‘U’ or ‘u’ (upper) that are often used as parameters to legacy BLAS implementations.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUBLAS_FILL_MODE_LOWER</td>
<td>the lower part of the matrix is filled</td>
</tr>
<tr>
<td>CUBLAS_FILL_MODE_UPPER</td>
<td>the upper part of the matrix is filled</td>
</tr>
</tbody>
</table>

2.2.1.3. cublasOperation_t

The cublasOperation_t type indicates which operation needs to be performed with the dense matrix. Its values correspond to Fortran characters ‘N’ or ‘n’ (non-transpose), ‘T’ or ‘t’ (transpose) and ‘C’ or ‘c’ (conjugate transpose) that are often used as parameters to legacy BLAS implementations.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUBLAS_OP_N</td>
<td>the non-transpose operation is selected</td>
</tr>
<tr>
<td>CUBLAS_OP_T</td>
<td>the transpose operation is selected</td>
</tr>
<tr>
<td>CUBLAS_OP_C</td>
<td>the conjugate transpose operation is selected</td>
</tr>
</tbody>
</table>

2.2.1.4. cusolverEigType_t

The cusolverEigType_t type indicates which type of eigenvalue solver is. Its values correspond to Fortran integer 1 (A*x = lambda*B*x), 2 (A*B*x = lambda*x), 3 (B*A*x = lambda*x), used as parameters to legacy LAPACK implementations.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
</table>
CUSOLVER_EIG_TYPE_1
CUSOLVER_EIG_TYPE_2
CUSOLVER_EIG_TYPE_3

2.2.1.5. cusolverEigMode_t

The **cusolverEigMode_t** type indicates whether or not eigenvectors are computed. Its values correspond to Fortran character 'N' (only eigenvalues are computed), 'V' (both eigenvalues and eigenvectors are computed) used as parameters to legacy LAPACK implementations.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_EIG_MODE_NOVECTOR</td>
<td>only eigenvalues are computed</td>
</tr>
<tr>
<td>CUSOLVER_EIG_MODE_VECTOR</td>
<td>both eigenvalues and eigenvectors are computed</td>
</tr>
</tbody>
</table>

2.2.1.6. cusolverIRSRefinement_t

The **cusolverIRSRefinement_t** type indicates which solver type would be used for the specific cusolver function. Most of our experimentation shows that CUSOLVER_IRS_REFINE_GMRES is the best option.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_IRS_REFINE_NOT_SET</td>
<td>Solver is not set, this value is what is set when creating the params structure. IRS solver will return error.</td>
</tr>
<tr>
<td>CUSOLVER_IRS_REFINE_NONE</td>
<td>No refinement solver, the IRS solver performs a factorisation followed by a solve without any refinement. For example if the IRS solver was cusolverDnIRSXgesv(), this is equivalent to a Xgesv routine without refinement and where the factorisation is carried out in the lowest precision. If for example the main precision was CUSOLVER_R_64F and the lowest was CUSOLVER_R_64F as well, then this is equivalent to a call to cusolverDnDgesv().</td>
</tr>
<tr>
<td>CUSOLVER_IRS_REFINE_CLASSICAL</td>
<td>Classical iterative refinement solver. Similar to the one used in LAPACK routines.</td>
</tr>
<tr>
<td>CUSOLVER_IRS_REFINE_GMRES</td>
<td>GMRES (Generalized Minimal Residual) based iterative refinement solver. In recent study, the GMRES method has drawn the scientific community attention for its ability to be used as refinement solver that outperforms the classical iterative refinement method. Based on our experimentation, we recommend this setting.</td>
</tr>
</tbody>
</table>
CUSOLVER_IRS_REFINE_CLASSICAL_GMRES

Classical iterative refinement solver that uses the GMRES (Generalized Minimal Residual) internally to solve the correction equation at each iteration. We call the **classical refinement iteration** the outer iteration while the GMRES is called inner iteration. Note that if the tolerance of the inner GMRES is set very low, let say to machine precision, then the outer classical refinement iteration will performs only one iteration and thus this option will behaves like CUSOLVER_IRS_REFINE_GMRES.

CUSOLVER_IRS_REFINE_GMRES_GMRES

Similar to CUSOLVER_IRS_REFINE_CLASSICAL_GMRES which consists of classical refinement process that uses GMRES to solve the inner correction system, here it is a GMRES (Generalized Minimal Residual) based iterative refinement solver that uses another GMRES internally to solve the preconditionned system.

### 2.2.1.7. cusolverDnIRSParams_t

This is a pointer type to an opaque cusolverDnIRSParams_t structure, which holds parameters for the iterative refinement linear solvers such as cusolverDnXgesv(). Use corresponding helper functions described below to either Create/Destroy this structure or Set/Get solver parameters.

### 2.2.1.8. cusolverDnIRSInfos_t

This is a pointer type to an opaque cusolverDnIRSInfos_t structure, which holds information about the performed call to an iterative refinement linear solver (e.g., cusolverDnXgesv()). Use corresponding helper functions described below to either Create/Destroy this structure or retrieve solve information.

### 2.2.1.9. cusolverDnFunction_t

The **cusolverDnFunction_t** type indicates which routine needs to be configured by cusolverDnSetAdvOptions(). The value CUSOLVERDN_GETRF corresponds to the routine Getrf.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVERDN_GETRF</td>
<td>corresponds to Getrf</td>
</tr>
</tbody>
</table>

### 2.2.1.10. cusolverAlgMode_t

The **cusolverAlgMode_t** type indicates which algorithm is selected by cusolverDnSetAdvOptions(). The set of algorithms supported for each routine is described in detail along with the routine documentation.

The default algorithm is **CUSOLVER_ALG_0**. The user can also provide **NULL** to use the default algorithm.
2.2.1.11. cusolverStatus_t
This is the same as cusolverStatus_t in the sparse LAPACK section.

2.2.2. cuSolverSP Types
The float, double, cuComplex, and cuDoubleComplex data types are supported. The first two are standard C data types, while the last two are exported from cuComplex.h.

2.2.2.1. cusolverSpHandle_t
This is a pointer type to an opaque cuSolverSP context, which the user must initialize by calling cusolverSpCreate() prior to calling any other library function. An un-initialized Handle object will lead to unexpected behavior, including crashes of cuSolverSP. The handle created and returned by cusolverSpCreate() must be passed to every cuSolverSP function.

2.2.2.2. cusparseMatDescr_t
We have chosen to keep the same structure as exists in cuSparse to describe the shape and properties of a matrix. This enables calls to either cuSparse or cuSolver using the same matrix description.

```c
typedef struct {
    cusparseMatrixType_t MatrixType;
    cusparseFillMode_t FillMode;
    cusparseDiagType_t DiagType;
    cusparseIndexBase_t IndexBase;
} cusparseMatDescr_t;
```

Please read documentation of CUSPARSE Library to understand each field of cusparseMatDescr_t.

2.2.2.3. cusolverStatus_t
This is a status type returned by the library functions and it can have the following values.

<table>
<thead>
<tr>
<th>cusolverStatus_t</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>The operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INIT</td>
<td>The cuSolver library was not initialized. This is usually caused by the lack</td>
</tr>
<tr>
<td></td>
<td>of a prior call, an error in the CUDA Runtime API called by the cuSolver</td>
</tr>
<tr>
<td></td>
<td>routine, or an error in the hardware setup.</td>
</tr>
<tr>
<td></td>
<td><strong>To correct:</strong> call cusolverCreate() prior to the function call; and check</td>
</tr>
<tr>
<td></td>
<td>that the hardware, an appropriate version of the driver, and the cuSolver</td>
</tr>
<tr>
<td></td>
<td>library are correctly installed.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_ALLOC_FAILED</td>
<td>Resource allocation failed inside the cuSolver library. This is usually</td>
</tr>
<tr>
<td></td>
<td>caused by a cudaMalloc() failure.</td>
</tr>
<tr>
<td></td>
<td><strong>To correct:</strong> prior to the function call, deallocate previously allocated</td>
</tr>
<tr>
<td></td>
<td>memory as much as possible.</td>
</tr>
</tbody>
</table>
CUSOLVER_STATUS_INVALID_VALUE
An unsupported value or parameter was passed to the function (a negative vector size, for example).
To correct: ensure that all the parameters being passed have valid values.

CUSOLVER_STATUS_ARCH_MISMATCH
The function requires a feature absent from the device architecture; usually caused by the lack of support for atomic operations or double precision.
To correct: compile and run the application on a device with compute capability 2.0 or above.

CUSOLVER_STATUS_EXECUTION_FAILED
The GPU program failed to execute. This is often caused by a launch failure of the kernel on the GPU, which can be caused by multiple reasons.
To correct: check that the hardware, an appropriate version of the driver, and the cuSolver library are correctly installed.

CUSOLVER_STATUS_INTERNAL_ERROR
An internal cuSolver operation failed. This error is usually caused by a cudaMemcpyAsync() failure.
To correct: check that the hardware, an appropriate version of the driver, and the cuSolver library are correctly installed. Also, check that the memory passed as a parameter to the routine is not being deallocated prior to the routine's completion.

CUSOLVER_STATUS_MATRIX_TYPE_NOT_SUPPORTED
The matrix type is not supported by this function. This is usually caused by passing an invalid matrix descriptor to the function.
To correct: check that the fields in descrA were set correctly.

2.2.3. cuSolverRF Types

cuSolverRF only supports double.

2.2.3.1. cusolverRfHandle_t
The cusolverRfHandle_t is a pointer to an opaque data structure that contains the cuSolverRF library handle. The user must initialize the handle by calling cusolverRfCreate() prior to any other cuSolverRF library calls. The handle is passed to all other cuSolverRF library calls.

2.2.3.2. cusolverRfMatrixFormat_t
The cusolverRfMatrixFormat_t is an enum that indicates the input/output matrix format assumed by the cusolverRfSetupDevice(), cusolverRfSetupHost(), cusolverRfResetValues(), cusolveRfExtractBundledFactorsHost() and cusolverRfExtractSplitFactorsHost() routines.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_MATRIX_FORMAT_CSR</td>
<td>matrix format CSR is assumed. (default)</td>
</tr>
</tbody>
</table>
CUSOLVER_MATRIX_FORMAT_CSC | matrix format CSC is assumed.

2.2.3.3. cusolverRfNumericBoostReport_t

The `cusolverRfNumericBoostReport_t` is an enum that indicates whether numeric boosting (of the pivot) was used during the `cusolverRfRefactor()` and `cusolverRfSolve()` routines. The numeric boosting is disabled by default.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_NUMERIC_BOOST_NOT_USED</td>
<td>numeric boosting not used. (default)</td>
</tr>
<tr>
<td>CUSOLVER_NUMERIC_BOOST_USED</td>
<td>numeric boosting used.</td>
</tr>
</tbody>
</table>

2.2.3.4. cusolverRfResetValuesFastMode_t

The `cusolverRfResetValuesFastMode_t` is an enum that indicates the mode used for the `cusolverRfResetValues()` routine. The fast mode requires extra memory and is recommended only if very fast calls to `cusolverRfResetValues()` are needed.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_RESET_VALUES_FAST_MODE_OFF</td>
<td>fast mode disabled. (default)</td>
</tr>
<tr>
<td>CUSOLVER_RESET_VALUES_FAST_MODE_ON</td>
<td>fast mode enabled.</td>
</tr>
</tbody>
</table>

2.2.3.5. cusolverRfFactorization_t

The `cusolverRfFactorization_t` is an enum that indicates which (internal) algorithm is used for refactorization in the `cusolverRfRefactor()` routine.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_FACTORIZATION_ALG0</td>
<td>algorithm 0. (default)</td>
</tr>
<tr>
<td>CUSOLVER_FACTORIZATION_ALG1</td>
<td>algorithm 1.</td>
</tr>
<tr>
<td>CUSOLVER_FACTORIZATION_ALG2</td>
<td>algorithm 2. Domino-based scheme.</td>
</tr>
</tbody>
</table>

2.2.3.6. cusolverRfTriangularSolve_t

The `cusolverRfTriangularSolve_t` is an enum that indicates which (internal) algorithm is used for triangular solve in the `cusolverRfSolve()` routine.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_TRIANGULAR_SOLVE_ALG1</td>
<td>algorithm 1. (default)</td>
</tr>
<tr>
<td>CUSOLVER_TRIANGULAR_SOLVE_ALG2</td>
<td>algorithm 2. Domino-based scheme.</td>
</tr>
</tbody>
</table>

2.2.3.7. cusolverRfUnitDiagonal_t

The `cusolverRfUnitDiagonal_t` is an enum that indicates whether and where the unit diagonal is stored in the input/output triangular factors.
in the `cusolverRfSetupDevice()`, `cusolverRfSetupHost()` and `cusolverRfExtractSplitFactorsHost()` routines.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_UNIT_DIAGONAL_STORED_L</td>
<td>unit diagonal is stored in lower triangular factor. (default)</td>
</tr>
<tr>
<td>CUSOLVER_UNIT_DIAGONAL_STORED_U</td>
<td>unit diagonal is stored in upper triangular factor.</td>
</tr>
<tr>
<td>CUSOLVER_UNIT_DIAGONAL_ASSUMED_L</td>
<td>unit diagonal is assumed in lower triangular factor.</td>
</tr>
<tr>
<td>CUSOLVER_UNIT_DIAGONAL_ASSUMED_U</td>
<td>unit diagonal is assumed in upper triangular factor.</td>
</tr>
</tbody>
</table>

2.2.3.8. `cusolverStatus_t`

The `cusolverStatus_t` is an enum that indicates success or failure of the cuSolverRF library call. It is returned by all the cuSolver library routines, and it uses the same enumerated values as the sparse and dense Lapack routines.

2.3. cuSolver Formats Reference

2.3.1. Index Base Format

The CSR or CSC format requires either zero-based or one-based index for a sparse matrix $A$. The GLU library supports only zero-based indexing. Otherwise, both one-based and zero-based indexing are supported in cuSolver.

2.3.2. Vector (Dense) Format

The vectors are assumed to be stored linearly in memory. For example, the vector

$$ x = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} $$

is represented as

$$ (x_1 \ x_2 \ \ldots \ x_n) $$

2.3.3. Matrix (Dense) Format

The dense matrices are assumed to be stored in column-major order in memory. The sub-matrix can be accessed using the leading dimension of the original matrix. For example, the $m \times n$ (sub-)matrix

$$ \begin{bmatrix} a_{1,1} & \ldots & a_{1,n} \\ a_{2,1} & \ldots & a_{2,n} \\ \vdots & \ddots & \vdots \\ a_{m,1} & \ldots & a_{m,n} \end{bmatrix} $$
is represented as

\[
\begin{pmatrix}
a_{1,1} & \ldots & a_{1,n} \\
a_{2,1} & \ldots & a_{2,n} \\
\vdots & \ddots & \vdots \\
a_{m,1} & \ldots & a_{m,n} \\
a_{l_{da,1}} & \ldots & a_{l_{da,n}}
\end{pmatrix}
\]

with its elements arranged linearly in memory as

\[
(a_{1,1} \ a_{2,1} \ \ldots \ a_{m,1} \ \ldots \ a_{l_{da,1}} \ \ldots \ a_{1,n} \ a_{2,n} \ \ldots \ a_{m,n} \ \ldots \ a_{l_{da,n}})
\]

where \( l_{da} \geq m \) is the leading dimension of \( A \).

### 2.3.4. Matrix (CSR) Format

In CSR format the matrix is represented by the following parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>type</th>
<th>size</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>( n )</td>
<td>(int)</td>
<td></td>
<td>the number of rows (and columns) in the matrix.</td>
</tr>
<tr>
<td>( \text{nnz} )</td>
<td>(int)</td>
<td></td>
<td>the number of non-zero elements in the matrix.</td>
</tr>
<tr>
<td>( \text{csrRowPtr} )</td>
<td>(int *)</td>
<td>( n+1 )</td>
<td>the array of offsets corresponding to the start of each row in the arrays ( \text{csrColInd} ) and ( \text{csrVal} ). This array has also an extra entry at the end that stores the number of non-zero elements in the matrix.</td>
</tr>
<tr>
<td>( \text{csrColInd} )</td>
<td>(int *)</td>
<td>( \text{nnz} )</td>
<td>the array of column indices corresponding to the non-zero elements in the matrix. It is assumed that this array is sorted by row and by column within each row.</td>
</tr>
<tr>
<td>( \text{csrVal} )</td>
<td>(S</td>
<td>D</td>
<td>C</td>
</tr>
</tbody>
</table>

Note that in our CSR format sparse matrices are assumed to be stored in row-major order, in other words, the index arrays are first sorted by row indices and then within each row by column indices. Also it is assumed that each pair of row and column indices appears only once.

For example, the \( 4 \times 4 \) matrix

\[
A = \begin{bmatrix}
1.0 & 3.0 & 0.0 & 0.0 \\
0.0 & 4.0 & 6.0 & 0.0 \\
2.0 & 5.0 & 7.0 & 8.0 \\
0.0 & 0.0 & 0.0 & 9.0
\end{bmatrix}
\]

is represented as

\[
\text{csrRowPtr} = (0 \ 2 \ 4 \ 8 \ 9)
\]
2.3.5. Matrix (CSC) Format

In CSC format the matrix is represented by the following parameters:

<table>
<thead>
<tr>
<th>parameter</th>
<th>type</th>
<th>size</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>(int)</td>
<td></td>
<td>the number of rows (and columns) in the matrix.</td>
</tr>
<tr>
<td>nnz</td>
<td>(int)</td>
<td></td>
<td>the number of non-zero elements in the matrix.</td>
</tr>
<tr>
<td>cscColPtr</td>
<td>(int *)</td>
<td>n+1</td>
<td>the array of offsets corresponding to the start of each column in the</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>arrays cscRowInd and cscVal. This array has also an extra entry at the</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>end that stores the number of non-zero elements in the matrix.</td>
</tr>
<tr>
<td>cscRowInd</td>
<td>(int *)</td>
<td>nnz</td>
<td>the array of row indices corresponding to the non-zero elements in the</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>matrix. It is assumed that this array is sorted by column and by row</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>within each column.</td>
</tr>
<tr>
<td>cscVal</td>
<td>(S</td>
<td>D</td>
<td>C</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>It is assumed that this array is sorted by column and by row within each</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>column.</td>
</tr>
</tbody>
</table>

Note that in our CSC format sparse matrices are assumed to be stored in column-major order, in other words, the index arrays are first sorted by column indices and then within each column by row indices. Also it is assumed that each pair of row and column indices appears only once.

For example, the 4x4 matrix

$$
A = \begin{pmatrix}
1.0 & 3.0 & 0.0 & 0.0 \\
0.0 & 4.0 & 6.0 & 0.0 \\
2.0 & 5.0 & 7.0 & 8.0 \\
0.0 & 0.0 & 0.0 & 9.0 \\
\end{pmatrix}
$$

2.4. cuSolverDN: dense LAPACK Function Reference

This chapter describes the API of cuSolverDN, which provides a subset of dense LAPACK functions.

2.4.1. cuSolverDN Helper Function Reference

The cuSolverDN helper functions are described in this section.

2.4.1.1. cuSolverDnCreate()

```
cusolverStatus_t
cusolverDnCreate(cusolverDnHandle_t *handle);
```

This function initializes the cuSolverDN library and creates a handle on the cuSolverDN context. It must be called before any other cuSolverDN API function is invoked. It allocates hardware resources necessary for accessing the GPU.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>output</td>
<td>the pointer to the handle to the cuSolverDN context.</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the initialization succeeded.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the CUDA Runtime initialization failed.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_ALLOC_FAILED</td>
<td>the resources could not be allocated.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_ARCH_MISMATCH</td>
<td>the device only supports compute capability 2.0 and above.</td>
</tr>
</tbody>
</table>

2.4.1.2. cuSolverDnDestroy()

```
cusolverStatus_t
cusolverDnDestroy(cusolverDnHandle_t handle);
```

This function releases CPU-side resources used by the cuSolverDN library.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>handle to the cuSolverDN library context.</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the shutdown succeeded.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
</tbody>
</table>
2.4.1.3. cusolverDnSetStream()

```c
 cusolverStatus_t
cusolverDnSetStream(cusolverDnHandle_t handle, cudaStream_t streamId)
```

This function sets the stream to be used by the cuSolverDN library to execute its routines.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>handle to the cuSolverDN library context.</td>
</tr>
<tr>
<td>streamId</td>
<td>host</td>
<td>input</td>
<td>the stream to be used by the library.</td>
</tr>
</tbody>
</table>

**Status Returned**

<table>
<thead>
<tr>
<th>Status Returned</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the stream was set successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
</tbody>
</table>

2.4.1.4. cusolverDnGetStream()

```c
 cusolverStatus_t
cusolverDnGetStream(cusolverDnHandle_t handle, cudaStream_t *streamId)
```

This function sets the stream to be used by the cuSolverDN library to execute its routines.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>handle to the cuSolverDN library context.</td>
</tr>
<tr>
<td>streamId</td>
<td>host</td>
<td>output</td>
<td>the stream to be used by the library.</td>
</tr>
</tbody>
</table>

**Status Returned**

<table>
<thead>
<tr>
<th>Status Returned</th>

</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the stream was set successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
</tbody>
</table>

2.4.1.5. cusolverDnCreateSyevjInfo()

```c
 cusolverStatus_t
cusolverDnCreateSyevjInfo(
    syevjInfo_t *info);
```

This function creates and initializes the structure of syevj, syevjBatched and sygvj to default values.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>output</td>
<td>the pointer to the structure of syevj.</td>
</tr>
</tbody>
</table>

**Status Returned**

<table>
<thead>
<tr>
<th>Status Returned</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the structure was initialized successfully.</td>
</tr>
</tbody>
</table>
CUSOLVER_STATUS_ALLOC_FAILED the resources could not be allocated.

2.4.1.6. cusolverDnDestroySyevjInfo()

cusolverStatus_t
cusolverDnDestroySyevjInfo(
    syevjInfo_t info);

This function destroys and releases any memory required by the structure.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>input</td>
<td>the structure of syevj.</td>
</tr>
</tbody>
</table>

Status Returned

CUSOLVER_STATUS_SUCCESS the resources are released successfully.

2.4.1.7. cusolverDnXsyevjSetTolerance()

cusolverStatus_t
cusolverDnXsyevjSetTolerance(
    syevjInfo_t info,
    double tolerance);

This function configures tolerance of syevj.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>in/out</td>
<td>the pointer to the structure of syevj.</td>
</tr>
<tr>
<td>tolerance</td>
<td>host</td>
<td>input</td>
<td>accuracy of numerical eigenvalues.</td>
</tr>
</tbody>
</table>

Status Returned

CUSOLVER_STATUS_SUCCESS the operation completed successfully.

2.4.1.8. cusolverDnXsyevjSetMaxSweeps()

cusolverStatus_t
cusolverDnXsyevjSetMaxSweeps(
    syevjInfo_t info,
    int max_sweeps);

This function configures maximum number of sweeps in syevj. The default value is 100.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>in/out</td>
<td>the pointer to the structure of syevj.</td>
</tr>
<tr>
<td>max_sweeps</td>
<td>host</td>
<td>input</td>
<td>maximum number of sweeps.</td>
</tr>
</tbody>
</table>

Status Returned

CUSOLVER_STATUS_SUCCESS the operation completed successfully.
### 2.4.1.9. cusolverDnXsyevjSetSortEig()

```c
 cusolverStatus_t
cusolverDnXsyevjSetSortEig(
    syevjInfo_t info,
    int sort_eig)
```

if `sort_eig` is zero, the eigenvalues are not sorted. This function only works for `syevjBatched`, `syevj` and `sygvj` always sort eigenvalues in ascending order. By default, eigenvalues are always sorted in ascending order.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>in/out</td>
<td>the pointer to the structure of syevj.</td>
</tr>
<tr>
<td>sort_eig</td>
<td>host</td>
<td>input</td>
<td>if <code>sort_eig</code> is zero, the eigenvalues are not sorted.</td>
</tr>
</tbody>
</table>

#### Status Returned

- **CUSOLVER_STATUS_SUCCESS**
  - the operation completed successfully.

### 2.4.1.10. cusolverDnXsyevjGetResidual()

```c
 cusolverStatus_t
cusolverDnXsyevjGetResidual(
    cusolverDnHandle_t handle,
    syevjInfo_t info,
    double *residual)
```

This function reports residual of `syevj` or `sygvj`. It does not support `syevjBatched`. If the user calls this function after `syevjBatched`, the error `CUSOLVER_STATUS_NOT_SUPPORTED` is returned.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>handle to the cuSolverDN library context.</td>
</tr>
<tr>
<td>info</td>
<td>host</td>
<td>input</td>
<td>the pointer to the structure of syevj.</td>
</tr>
<tr>
<td>residual</td>
<td>host</td>
<td>output</td>
<td>residual of syevj.</td>
</tr>
</tbody>
</table>

#### Status Returned

- **CUSOLVER_STATUS_SUCCESS**
  - the operation completed successfully.
- **CUSOLVER_STATUS_NOT_SUPPORTED**
  - does not support batched version

### 2.4.1.11. cusolverDnXsyevjGetSweeps()

```c
 cusolverStatus_t
cusolverDnXsyevjGetSweeps(
    cusolverDnHandle_t handle,
    syevjInfo_t info,
    int *executed_sweeps)
```
This function reports number of executed sweeps of `syevj` or `sygvj`. It does not support `syevjBatched`. If the user calls this function after `syevjBatched`, the error `CUSOLVER_STATUS_NOT_SUPPORTED` is returned.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>handle to the cuSolverDN library context.</td>
</tr>
<tr>
<td>info</td>
<td>host</td>
<td>input</td>
<td>the pointer to the structure of <code>syevj</code>.</td>
</tr>
<tr>
<td>executed_sweeps</td>
<td>host</td>
<td>output</td>
<td>number of executed sweeps.</td>
</tr>
</tbody>
</table>

### Status Returned

<table>
<thead>
<tr>
<th>Status Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CUSOLVER_STATUS_SUCCESS</code></td>
</tr>
<tr>
<td>the operation completed successfully.</td>
</tr>
<tr>
<td><code>CUSOLVER_STATUS_NOT_SUPPORTED</code></td>
</tr>
<tr>
<td>does not support batched version</td>
</tr>
</tbody>
</table>

#### 2.4.1.12. `cusolverDnCreateGesvdjInfo()`

```c
 cusolverStatus_t
cusolverDnCreateGesvdjInfo(  
gesvdjInfo_t *info);
```

This function creates and initializes the structure of `gesvdj` and `gesvdjBatched` to default values.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>output</td>
<td>the pointer to the structure of <code>gesvdj</code>.</td>
</tr>
</tbody>
</table>

### Status Returned

<table>
<thead>
<tr>
<th>Status Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CUSOLVER_STATUS_SUCCESS</code></td>
</tr>
<tr>
<td>the structure was initialized successfully.</td>
</tr>
<tr>
<td><code>CUSOLVER_STATUS_ALLOC_FAILED</code></td>
</tr>
<tr>
<td>the resources could not be allocated.</td>
</tr>
</tbody>
</table>

#### 2.4.1.13. `cusolverDnDestroyGesvdjInfo()`

```c
 cusolverStatus_t
cusolverDnDestroyGesvdjInfo(  
gesvdjInfo_t info);
```

This function destroys and releases any memory required by the structure.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>input</td>
<td>the structure of <code>gesvdj</code>.</td>
</tr>
</tbody>
</table>

### Status Returned

<table>
<thead>
<tr>
<th>Status Returned</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CUSOLVER_STATUS_SUCCESS</code></td>
</tr>
<tr>
<td>the resources are released successfully.</td>
</tr>
</tbody>
</table>
2.4.1.14. cusolverDnXgesvdjSetTolerance()

```c
 cusolverStatus_t
cusolverDnXgesvdjSetTolerance(
    gesvdjInfo_t info,
    double tolerance)
```

This function configures tolerance of *gesvdj*.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>in/out</td>
<td>the pointer to the structure of gesvdj.</td>
</tr>
<tr>
<td>tolerance</td>
<td>host</td>
<td>input</td>
<td>accuracy of numerical singular values.</td>
</tr>
</tbody>
</table>

**Status Returned**

- **CUSOLVER_STATUS_SUCCESS** the operation completed successfully.

2.4.1.15. cusolverDnXgesvdjSetMaxSweeps()

```c
 cusolverStatus_t
cusolverDnXgesvdjSetMaxSweeps(
    gesvdjInfo_t info,
    int max_sweeps)
```

This function configures maximum number of sweeps in *gesvdj*. The default value is 100.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>in/out</td>
<td>the pointer to the structure of gesvdj.</td>
</tr>
<tr>
<td>max_sweeps</td>
<td>host</td>
<td>input</td>
<td>maximum number of sweeps.</td>
</tr>
</tbody>
</table>

**Status Returned**

- **CUSOLVER_STATUS_SUCCESS** the operation completed successfully.

2.4.1.16. cusolverDnXgesvdjSetSortEig()

```c
 cusolverStatus_t
cusolverDnXgesvdjSetSortEig(
    gesvdjInfo_t info,
    int sort_svd)
```

if `sort_svd` is zero, the singular values are not sorted. This function only works for *gesvdjBatched*. *gesvdj* always sorts singular values in descending order. By default, singular values are always sorted in descending order.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>info</td>
<td>host</td>
<td>in/out</td>
<td>the pointer to the structure of gesvdj.</td>
</tr>
<tr>
<td>sort_svd</td>
<td>host</td>
<td>input</td>
<td>if <code>sort_svd</code> is zero, the singular values are not sorted.</td>
</tr>
</tbody>
</table>
Status Returned

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the operation completed successfully.</td>
</tr>
</tbody>
</table>

2.4.1.17. cusolverDnXgesvdjGetResidual()

cusolverStatus_t
cusolverDnXgesvdjGetResidual(
    cusolverDnHandle_t handle,
    gesvdjInfo_t info,
    double *residual)

This function reports residual of gesvdj. It does not support gesvdjBatched. If the user calls this function after gesvdjBatched, the error CUSOLVER_STATUS_NOT_SUPPORTED is returned.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>handle to the cuSolverDN library context.</td>

</tbody>
</table>

2.4.1.18. cusolverDnXgesvdjGetSweeps()

cusolverStatus_t
cusolverDnXgesvdjGetSweeps(
    cusolverDnHandle_t handle,
    gesvdjInfo_t info,
    int *executed_sweeps)

This function reports number of executed sweeps of gesvdj. It does not support gesvdjBatched. If the user calls this function after gesvdjBatched, the error CUSOLVER_STATUS_NOT_SUPPORTED is returned.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Memory</th>
<th>In/out</th>

<td>does not support batched version</td>
</tr>
</tbody>
</table>
2.4.1.19. cusolverDnIRSParamsCreate()
cusolverStatus_t
cusolverDnIRSParamsCreate(cusolverDnIRSParams_t *params);

This function creates and initializes the structure of parameters for an IRS solver such as the cusolverDnIRSXgesv() or the cusolverDnIRSXgels() functions to default values. The params structure created by this function can be used by one or more call to the same or to a different IRS solver. Note that, in CUDA-10.2, the behavior was different and a new params structure was needed to be created per each call to an IRS solver. Also note that, the user can also change configurations of the params then call a new IRS instance, but be careful that the previous call was done because any change to the configuration before that the previous call was done could affect it.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>

<td>The resources could not be allocated.</td>
</tr>
</tbody>
</table>

2.4.1.20. cusolverDnIRSParamsDestroy()
cusolverStatus_t
cusolverDnIRSParamsDestroy(cusolverDnIRSParams_t params);

This function destroys and releases any memory required by the Params structure.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>params</td>
<td>host</td>

</tr>
</tbody>
</table>

2.4.1.21. cusolverDnIRSParamsSetSolverPrecisions()
cusolverStatus_t
cusolverDnIRSParamsSetSolverPrecisions(
  cusolverDnIRSParams_t params,
  cusolverPrecType_t solver_main_precision,
  cusolverPrecType_t solver_lowest_precision );
This function set both, the main and the lowest precision for the Iterative Refinement Solver (IRS). By main precision, we mean the precision of the Input and Output datatype. By lowest precision, we mean the solver is allowed to use as lowest computational precision during the LU factorization process. Note that, the user has to set both the main and lowest precision before a first call to the IRS solver because they are NOT set by default with the params structure creation, as it depends on the Input/Output data type and user request. It is a wrapper to both `cusolverDnIRSParamsSetSolverMainPrecision()` and `cusolverDnIRSParamsSetSolverLowestPrecision()`. All possible combinations of main/lowest precision are described in the table below. Usually the lowest precision defines the speedup that can be achieved. The ratio of the performance of the lowest precision over the main precision (e.g., Inputs/Outputs datatype) define somehow the upper bound of the speedup that could be obtained. More precisely, it depends on many factors, but for large matrices sizes, it is the ratio of the matrix-matrix rank-k product (e.g., Gemm where K is 256 and M=N=size of the matrix) that define the possible speedup. For instance, if the inout precision is real double precision `CUSOLVER_R_64F` and the lowest precision is `CUSOLVER_R_32F`, then we can expect a speedup of at most 2X for large problem sizes. If the lowest precision was `CUSOLVER_R_16F`, then we can expect 3X-4X. A reasonable strategy should take the number of right-hand sides, the size of the matrix as well as the convergence rate into account.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>

2.4.1.22. cusolverDnIRSParamsSetSolverMainPrecision()

cusolverStatus_t
cusolverDnIRSParamsSetSolverMainPrecision(
    cusolverDnIRSParams_t params,
    cusolverPrecType_t solver_main_precision);

This function sets the main precision for the Iterative Refinement Solver (IRS). By main precision, we mean, the type of the Input and Output data. Note that, the user has to set both the main and lowest precision before a first call to the IRS solver because they are NOT set by default with the params structure creation, as it depends on the Input Output data type and user request. user can set it by either calling this function or by calling cusolverDnIRSParamsSetSolverPrecisions() which set both the main and the lowest precision together. All possible combinations of main/lowest precision are described in the table in the cusolverDnIRSParamsSetSolverPrecisions() section above.

<table>

2.4.1.23. cusolverDnIRSParamsSetSolverLowestPrecision()

cusolverStatus_t
cusolverDnIRSParamsSetSolverLowestPrecision(
    cusolverDnIRSParams_t params,
    cusolverPrecType_t lowest_precision_type);

This function sets the lowest precision that will be used by Iterative Refinement Solver. By lowest precision, we mean the solver is allowed to use as lowest computational precision during the LU factorization process. Note that, the user has to set both the main and lowest precision before a first call to the IRS solver because they are NOT set by default with the params structure creation, as it depends on the Input Output data type and user request. Usually the lowest precision defines the speedup that can be achieved. The ratio of the performance of the lowest precision over the main precision (e.g., Inputs/Outputs datatype) define somehow the upper bound of the speedup that
could be obtained. More precisely, it depends on many factors, but for large matrices sizes, it is the ratio of the matrix-matrix rank-k product (e.g., GEMM where K is 256 and M=N=size of the matrix) that define the possible speedup. For instance, if the in/out precision is real double precision CUSOLVER_R_64F and the lowest precision is CUSOLVER_R_32F, then we can expect a speedup of at most 2X for large problem sizes. If the lowest precision was CUSOLVER_R_16F, then we can expect 3X-4X. A reasonable strategy should take the number of right-hand sides, the size of the matrix as well as the convergence rate into account.

2.4.1.24. cusolverDnIRSParamsSetRefinementSolver()

cusolverStatus_t
cusolverDnIRSParamsSetRefinementSolver(  
cusolverDnIRSParams_t params,  
cusolverIRSRefinement_t solver);  

This function sets the refinement solver to be used in the Iterative Refinement Solver functions such as the cusolverDnIRSXgesv() or the cusolverDnIRSXgels() functions. Note that, the user has to set the refinement algorithm before a first call to the IRS solver because it is NOT set by default with the creating of params. Details about values that can be set to and theirs meaning are described in the table below.

<table>

</tr>
<tr>
<td>CUSOLVER_InRS_REFINE_GMRES</td>
<td>GMRES (Generalized Minimal Residual) based iterative refinement solver. In recent study, the GMRES method has drawn the scientific community attention for its ability to be used as refinement solver that outperforms the classical iterative refinement method. Based on our experimentation, we recommend this setting.</td>
</tr>
<tr>
<td>CUSOLVER_InRS_REFINE_CLASSICAL_GMRES</td>
<td>Classical iterative refinement solver that uses the GMRES (Generalized Minimal Residual) internally to solve the correction equation at each iteration. We call the classical refinement iteration the outer iteration while the GMRES is called inner iteration. Note that if the tolerance of the inner GMRES is set very low, let say to machine precision, then the outer classical refinement iteration will perform only one iteration and thus this option will behaves like CUSOLVER_InRS_REFINE_GMRES.</td>
</tr>
<tr>
<td>CUSOLVER_InRS_REFINE_GMRES_GMRES</td>
<td>Similar to CUSOLVER_InRS_REFINE_CLASSICAL_GMRES which consists of classical refinement process that uses GMRES to solve the inner correction system, here it is a GMRES (Generalized Minimal Residual) based iterative refinement solver that uses another GMRES internally to solve the preconditioned system.</td>
</tr>
</tbody>
</table>

### 2.4.1.25. cusolverDnIRSParamsSetTol()

```c
 cusolverStatus_t
 cusolverDnIRSParamsSetTol(  
   cusolverDnIRSParams_t params,  
   double val );
```

This function sets the tolerance for the refinement solver. By default it is such that, all the RHS satisfy:

\[ R \leq \sqrt{N} \times \text{XNRM} \times \text{ANRM} \times \text{EPS} \times \text{BWDMAX} \]
- RNRM is the infinity-norm of the residual
- XNRM is the infinity-norm of the solution
- ANRM is the infinity-operator-norm of the matrix A
- EPS is the machine epsilon for the Inputs/Outputs datatype that matches LAPACK `<X>LAMCH('Epsilon')`
- BWDMAX, the value BWDMAX is fixed to 1.0

The user can use this function to change the tolerance to a lower or higher value. Our goal is to give the user more control such a way he can investigate and control every detail of the IRS solver. Note the, the tolerance value is always in real double precision whatever the Inputs/Outputs datatype is.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>

<th>The operation completed successfully.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_IRS_PARAMS_NOT_INITIALIZED</td>
<td>The Params structure was not created.</td>
</tr>
</tbody>
</table>

### 2.4.1.26. cusolverDnIRSParamsSetTolInner()

```c
 cusolverStatus_t
cusolverDnIRSParamsSetTolInner(
    cusolverDnIRSParams_t params,
    double val);
```

This function sets the tolerance for the inner refinement solver when the refinement solver consists of two-levels solver (e.g., CUSOLVER_IRS_REFINE_CLASSICAL_GMRES or CUSOLVER_IRS_REFINE_GMRES_GMRES cases). It is not referenced in case of one level refinement solver such as CUSOLVER_IRS_REFINE_CLASSICAL or CUSOLVER_IRS_REFINE_GMRES. It is set to 1e-4 by default. This function set the tolerance for the inner solver (e.g. the inner GMRES). For example, if the Refinement Solver was set to CUSOLVER_IRS_REFINE_CLASSICAL_GMRES, setting this tolerance mean that the inner GMRES solver will converge to that tolerance at each outer iteration of the classical refinement solver. Our goal is to give the user more control such a way he can investigate and control every detail of the IRS solver. Note the, the tolerance value is always in real double precision whatever the Inputs/Outputs datatype is.

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>The operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_IRS_PARAMS_NOT_INITIALIZED</td>
<td>The Params structure was not created.</td>
</tr>
</tbody>
</table>

### 2.4.1.27. cusolverDnIRSParamsSetMaxIters()

```c
 cusolverStatus_t
 cusolverDnIRSParamsSetMaxIters(
    cusolverDnIRSParams_t params,
    int max_iters);
```

This function sets the total number of allowed refinement iterations after which the solver will stop. Total means any iteration which means the sum of the outer and the inner iterations (inner is meaningful when two-levels refinement solver is set). Default value is set to 50. Our goal is to give the user more control such a way he can investigate and control every detail of the IRS solver.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>params</td>
<td>host</td>
<td>in/out</td>
<td>The cusolverDnIRSParams_t Params structure</td>
</tr>
<tr>
<td>max_iters</td>
<td>host</td>
<td>input</td>
<td>Maximum total number of iterations allowed for the refinement solver</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>Status Returned</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>The operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_IRS_PARAMS_NOT_INITIALIZED</td>
<td>The Params structure was not created.</td>
</tr>
</tbody>
</table>

### 2.4.1.28. cusolverDnIRSParamsSetMaxItersInner()

```c
 cusolverStatus_t
 cusolverDnIRSParamsSetMaxItersInner(
    cusolverDnIRSParams_t params,
    cusolver_int_t maxiters_inner);
```

This function sets the maximal number of iterations allowed for the inner refinement solver. It is not referenced in case of one level refinement solver such as CUSOLVER_IRS_REFINE_CLASSICAL or CUSOLVER_IRS_REFINE_GMRES. The inner refinement solver will stop after reaching either the inner tolerance or the MaxItersInner value. By default, it is set to 50. Note that this value could not be larger than the MaxIters since MaxIters is the total number of allowed iterations. Note that, if the user call cusolverDnIRSParamsSetMaxIters after calling this function, the SetMaxIters has priority and will overwrite MaxItersInner to the minimum value of (MaxIters, MaxItersInner).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>params</td>
<td>host</td>
<td>in/out</td>
<td>The cusolverDnIRSParams_t Params structure</td>
</tr>
<tr>
<td>maxiters_inner</td>
<td>host</td>
<td>input</td>
<td>Maximum number of allowed inner iterations for the inner refinement</td>
</tr>
</tbody>
</table>
solver. Meaningful when the refinement solver is a two-levels solver such as CUSOLVER_IRS_REFINE_CLASSICAL_GMRES or CUSOLVER_IRS_REFINE_GMRES_GMRES. Value should be less or equal to MaxIters.

<table>
<thead>
<tr>
<th>Status Returned</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>The operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_IRS_PARAMS_NOT_INITIALIZED</td>
<td>The Params structure was not created.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_IRS_PARAMS_INVALID</td>
<td>if the value was larger than MaxIters.</td>
</tr>
</tbody>
</table>

### 2.4.1.29. cusolverDnIRSParamsEnableFallback()

cusolverStatus_t
    cusolverDnIRSParamsEnableFallback(
        cusolverDnIRSParams_t params);

This function enable the fallback to the main precision in case the Iterative Refinement Solver (IRS) failed to converge. In other term, if the IRS solver failed to converge, the solver will return a no convergence code (e.g., niter < 0), but can either return the non-convergent solution as it is (e.g., disable fallback) or can fallback (e.g., enable fallback) to the main precision (which is the precision of the Inputs/Outputs data) and solve the problem from scratch returning the good solution. This is the behavior by default, and it will guarantee that the IRS solver always provide the good solution. This function is provided because we provided `cusolverDnIRSParamsDisableFallback` which allow the user to disable the fallback and thus this function allow him to re-enable it.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>params</td>
<td>host</td>
<td>in/out</td>
<td>The cusolverDnIRSParams_t Params structure</td>
</tr>
</tbody>
</table>

### Status Returned

| CUSOLVER_STATUS_SUCCESS                  | The operation completed successfully.             |
| CUSOLVER_STATUS_IRS_PARAMS_NOT_INITIALIZED | The Params structure was not created.             |

### 2.4.1.30. cusolverDnIRSParamsDisableFallback()

cusolverStatus_t
    cusolverDnIRSParamsDisableFallback(
        cusolverDnIRSParams_t params);

This function disables the fallback to the main precision in case the Iterative Refinement Solver (IRS) failed to converge. In other term, if the IRS solver failed to converge, the solver will return a no convergence code (e.g., niter < 0), but can either return the non-convergent solution as it is (e.g., disable fallback) or can fallback (e.g., enable fallback) to the main precision (which is the precision of the Inputs/Outputs data) and solve the problem from scratch returning the good solution. This function
disables the fallback and the returned solution is whatever the refinement solver was able to reach before it returns. Disabling fallback does not guarantee that the solution is the good one. However, for some users, who want to keep getting the solution of the lower precision, in case the IRS did not converge after certain number of iterations, they need to disable the fallback. The user can re-enable it by calling \texttt{cusolverDnIRSParamsEnableFallback}.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>params</td>
<td>host</td>

</tr>
</tbody>
</table>

### 2.4.1.31. \texttt{cusolverDnIRSParamsGetMaxIters()}

```c

cusolverStatus_t
cusolverDnIRSParamsGetMaxIters(
    cusolverDnIRSParams_t params,
    cusolver_int_t *maxiters);
```

This function returns the current setting in the params structure for the maximal allowed number of iterations (e.g., either the default MaxIters, or the one set by the user in case he set it using \texttt{cusolverDnIRSParamsSetMaxIters}). Note that, this function returns the current setting in the params configuration and not to be confused with the \texttt{cusolverDnIRSInfosGetMaxIters} which return the maximal allowed number of iterations for a particular call to an IRS solver. To be clearer, the params structure can be used for many calls to an IRS solver. A user can change the allowed MaxIters between calls while the Infos structure in \texttt{cusolverDnIRSInfosGetMaxIters} contains information about a particular call and cannot be reused for different call, and thus, \texttt{cusolverDnIRSInfosGetMaxIters} return the allowed MaxIters for that call.

<table>
<thead>
<tr>
<th>parameter</th>

</tr>
<tr>
<td>\texttt{CUSOLVER_STATUS_IRS_PARAMS_NOT_INITIALIZED}</td>
</tr>
</tbody>
</table>
2.4.1.32. cusolverDnIRSInfosCreate()

cusolverStatus_t
cusolverDnIRSInfosCreate(
    cusolverDnIRSInfos_t* infos )

This function creates and initializes the Infos structure that will hold the refinement information of an Iterative Refinement Solver (IRS) call. Such information includes the total number of iterations that was needed to converge (Niters), the outer number of iterations (meaningful when two-levels preconditioner such as CUSOLVER_IRS_REFINE_CLASSICAL_GMRES is used), the maximal number of iterations that was allowed for that call, and a pointer to the matrix of the convergence history residual norms. The Infos structure need to be created before a call to an IRS solver. The Infos structure is valid for only one call to an IRS solver, since it holds info about that solve and thus each solve will requires its own Infos structure.

<table>
<thead>
<tr>

</tr>
<tr>
<td>CUSOLVER_STATUS_ALLOC_FAILED</td>
</tr>
</tbody>
</table>

2.4.1.33. cusolverDnIRSInfosDestroy()

cusolverStatus_t
cusolverDnIRSInfosDestroy(
    cusolverDnIRSInfos_t infos )

This function destroys and releases any memory required by the Infos structure. This function destroys all the informations (e.g., Niters performed, OuterNiters performed, residual history etc) about a solver call, thus, a user is supposed to call it once he is done from the informations he need.

<table>
<thead>
<tr>
<th>parameter</th>

2.4.1.34. cusolverDnIRSInfosGetMaxIters()

cusolverStatus_t
cusolverDnIRSInfosGetMaxIters(
    cusolverDnIRSInfos_t infos,
    cusolver_int_t *maxiters );
This function returns the maximal allowed number of iterations that was set for the corresponding call to the IRS solver. Note that, this function returns the setting that was set when that call happened and not to be confused with the \texttt{cusolverDnIRSParamsGetMaxIters} which return the current setting in the params configuration structure. To be clearer, the params structure can be used for many calls to an IRS solver. A user can change the allowed MaxIters between calls while the Infos structure in \texttt{cusolverDnIRSInfosGetMaxIters} contains information about a particular call and cannot be reused for different call, and thus \texttt{cusolverDnIRSInfosGetMaxIters} return the allowed MaxIters for that call.

2.4.1.35. \texttt{cusolverDnIRSInfosGetNiters()}

\begin{verbatim}
cusolverStatus_t cusolverDnIRSInfosGetNiters(  
cusolverDnIRSInfos_t infos,  
cusolver_int_t *niters );
\end{verbatim}

This function returns the total number of iterations performed by the IRS solver. If it was negative it means that the IRS solver did not converge and if the user did not disable the fallback to full precision, then the fallback to a full precision solution happened and solution is good. Please refer to the description of negative niters values in the corresponding IRS linear solver functions such as \texttt{cusolverDnXgesv()} or \texttt{cusolverDnXgels()}

<table>
<thead>
<tr>

2.4.1.36. \texttt{cusolverDnIRSInfosGetOuterNiters()}

\begin{verbatim}
cusolverStatus_t cusolverDnIRSInfosGetOuterNiters(  
cusolverDnIRSInfos_t infos,  
cusolver_int_t *outer_niters );
\end{verbatim}
This function returns the number of iterations performed by the outer refinement loop of the IRS solver. When the refinement solver consists of a one level solver such as CUSOLVER_IRS_REFINE_CLASSICAL or CUSOLVER_IRS_REFINE_GMRES, it is the same as Niters. When the refinement solver consists of a two-levels solver such as CUSOLVER_IRS_REFINE_CLASSICAL_GMRES or CUSOLVER_IRS_REFINE_GMRES_GMRES, it is the number of iterations of the outer loop. See description of cusolverIRSRefinementSolver_t section for more details.

<table>
<thead>

</tbody>
</table>

**Status Returned**

| CUSOLVER_STATUS_SUCCESS               | The operation completed successfully. |
| CUSOLVER_STATUS_IRS_INFOS_NOT_INITIALIZED | The Infos structure was not created. |

### 2.4.1.37. cusolverDnIRSInfosRequestResidual()

```c
 cusolverStatus_t cusolverDnIRSInfosRequestResidual(
     cusolverDnIRSInfos_t infos );
```

This function, once called, tell the IRS solver to store the convergence history (residual norms) of the refinement phase in a matrix, that could be accessed via a pointer returned by the `cusolverDnIRSInfosGetResidualHistory()` function.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>infos</td>
<td>host</td>
<td>in</td>
<td>The cusolverDnIRSInfos_t Infos structure</td>
</tr>
</tbody>
</table>

**Status Returned**

| CUSOLVER_STATUS_SUCCESS               | The operation completed successfully. |
| CUSOLVER_STATUS_IRS_INFOS_NOT_INITIALIZED | The Infos structure was not created. |

### 2.4.1.38. cusolverDnIRSInfosGetResidualHistory()

```c
 cusolverStatus_t
cusolverDnIRSInfosGetResidualHistory(
     cusolverDnIRSInfos_t infos, 
     void **residual_history );
```

If the user called `cusolverDnIRSInfosRequestResidual()` before the call to the IRS function, then the IRS solver will store the convergence history (residual norms) of the refinement phase in a matrix, that could be accessed via a pointer returned by this function. The datatype of the residual norms depends on the input and output data type. If the Inputs/Outputs datatype is double precision real or complex (CUSOLVER_R_FP64 or CUSOLVER_C_FP64), this residual will be of type real double precision (FP64) double, otherwise if the Inputs/Outputs datatype is single precision real or complex
(CUSOLVER_R_FP32 or CUSOLVER_C_FP32), this residual will be real single precision FP32 float.

The residual history matrix consists of two columns (even for the multiple right-hand side case NRHS) of MaxIters+1 row, thus a matrix of size (MaxIters+1,2). Only the first OuterNiters+1 rows contains the residual norms the other (e.g., OuterNiters +2:Maxiters+1) are garbage. On the first column, each row “i” specify the total number of iterations happened till this outer iteration “i” and on the second columns the residual norm corresponding to this outer iteration “i”. Thus, the first row (e.g., outer iteration “0”) consists of the initial residual (e.g., the residual before the refinement loop start) then the consecutive rows are the residual obtained at each outer iteration of the refinement loop. Note, it only consists of the history of the outer loop.

If the refinement solver was CUSOLVER_IRS_REFINE_CLASSICAL or CUSOLVER_IRS_REFINE_GMRES, then OuterNiters=Niters (Niters is the total number of iterations performed) and there is Niters+1 rows of norms that correspond to the Niters outer iterations.

If the refinement solver was CUSOLVER_IRS_REFINE_CLASSICAL_GMRES or CUSOLVER_IRS_REFINE_GMRES_GMRES, then OuterNiters <= Niters corresponds to the outer iterations performed by the outer refinement loop. Thus, there is OuterNiters +1 residual norms where row “i” correspond to the outer iteration “i” and the first column specify the total number of iterations (outer and inner) that were performed till this step the second columns correspond to the residual norm at this step.

For example, let say the user specify CUSOLVER_IRS_REFINE_CLASSICAL_GMRES as a refinement solver and let say it needed 3 outer iterations to converge and 4,3,3 inner iterations at each outer respectively. This consists of 10 total iterations. Row 0 correspond to the first residual before the refinement start, so it has 0 in its first column. On row 1 which correspond to the outer iteration 1, it will be shown 4 (4 is the total number of iterations that were performed till now) on row 2, it will be 7 and on row 3 it will be 10.

As summary, let define ldh=Maxiters+1, the leading dimension of the residual matrix. then residual_history[i] shows the total number of iterations performed at the outer iteration “i” and residual_history[i+ldh] correspond to the norm of the residual at this outer iteration.

2.4.2. Dense Linear Solver Reference

This chapter describes linear solver API of cuSolverDN, including Cholesky factorization, LU with partial pivoting, QR factorization and Bunch-Kaufman (LDLT) factorization.

2.4.2.1. cusolverDn<t>potrf()

These helper functions calculate the necessary size of work buffers.

```c
cusolverStatus_t
cusolverDnSpotrf_bufferSize(cusolverDnHandle_t handle,
                           cublasFillMode_t uplo,
                           int n,
                           float *A,
                           int lda,
                           int *Lwork);

cusolverStatus_t
cusolverDnDpotrf_bufferSize(cusolveDnHandle_t handle,
                           cublasFillMode_t uplo,
                           int n,
                           double *A,
                           int lda,
                           int *Lwork);

cusolverStatus_t
cusolverDnCpotrf_bufferSize(cusolverDnHandle_t handle,
                           cublasFillMode_t uplo,
                           int n,
                           cuComplex *A,
                           int lda,
                           int *Lwork);

cusolverStatus_t
cusolverDnZpotrf_bufferSize(cusolverDnHandle_t handle,
                           cublasFillMode_t uplo,
                           int n,
                           cuDoubleComplex *A,
                           int lda,
                           int *Lwork);```
The S and D data types are real valued single and double precision, respectively.

cusolverStatus_t
cusolverDnSpotrf(cusolverDnHandle_t handle,  
cublasFillMode_t uplo,  
    int n,  
    float *A,  
    int lda,  
    float *Workspace,  
    int Lwork,  
    int *devInfo );

cusolverStatus_t
cusolverDnDpotrf(cusolverDnHandle_t handle,  
cublasFillMode_t uplo,  
    int n,  
    double *A,  
    int lda,  
    double *Workspace,  
    int Lwork,  
    int *devInfo );

The C and Z data types are complex valued single and double precision, respectively.

cusolverStatus_t
cusolverDnCpotrf(cusolverDnHandle_t handle,  
cublasFillMode_t uplo,  
    int n,  
    cuComplex *A,  
    int lda,  
    cuComplex *Workspace,  
    int Lwork,  
    int *devInfo );

cusolverStatus_t
cusolverDnZpotrf(cusolverDnHandle_t handle,  
cublasFillMode_t uplo,  
    int n,  
    cuDoubleComplex *A,  
    int lda,  
    cuDoubleComplex *Workspace,  
    int Lwork,  
    int *devInfo );

This function computes the Cholesky factorization of a Hermitian positive-definite matrix.

\( A \) is a \( n \times n \) Hermitian matrix, only lower or upper part is meaningful. The input parameter \( \text{uplo} \) indicates which part of the matrix is used. The function would leave other part untouched.

If input parameter \( \text{uplo} \) is \text{CUBLAS_FILL_MODE_LOWER}, only lower triangular part of \( A \) is processed, and replaced by lower triangular Cholesky factor \( L \).

\[ A = L \cdot L^H \]

If input parameter \( \text{uplo} \) is \text{CUBLAS_FILL_MODE_UPPER}, only upper triangular part of \( A \) is processed, and replaced by upper triangular Cholesky factor \( U \).
The user has to provide working space which is pointed by input parameter `Workspace`. The input parameter `Lwork` is size of the working space, and it is returned by `potrf_bufferSize()`.

If Cholesky factorization failed, i.e. some leading minor of \( A \) is not positive definite, or equivalently some diagonal elements of \( L \) or \( U \) is not a real number. The output parameter `devInfo` would indicate smallest leading minor of \( A \) which is not positive definite.

If output parameter `devInfo = -i` (less than zero), the \( i \)-th parameter is wrong (not counting handle).

2.4.2.2. cusolverDnPotrf()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
 cusolverStatus_t
cusolverDnPotrf_bufferSize(    cusolverDnHandle_t handle,    cusolverDnParams_t params,    cublasFillMode_t uplo,    int64_t n,    cudaDataType dataTypeA,    const void *A,    int64_t lda,    cudaDataType computeType,    size_t *workspaceInBytes )
```

The routine below

```c
 cusolverStatus_t
cusolverDnPotrf(    cusolverDnHandle_t handle,    cusolverDnParams_t params,    cublasFillMode_t uplo,    int64_t n,    cudaDataType dataTypeA,    void *A,    int64_t lda,    cudaDataType computeType,    void *pBuffer,    size_t workspaceInBytes,    int *info )
```

computes the Cholesky factorization of a Hermitian positive-definite matrix using the generic API interface.

**A** is a \( n \times n \) Hermitian matrix, only lower or upper part is meaningful. The input parameter **uplo** indicates which part of the matrix is used. The function would leave other part untouched.

If input parameter **uplo** is **CUBLAS_FILL_MODE_LOWER**, only lower triangular part of \( A \) is processed, and replaced by lower triangular Cholesky factor \( L \).

\[
A = LL^H
\]

If input parameter **uplo** is **CUBLAS_FILL_MODE_UPPER**, only upper triangular part of \( A \) is processed, and replaced by upper triangular Cholesky factor \( U \).

\[
A = U^H U
\]

The user has to provide working space which is pointed by input parameter **pBuffer**. The input parameter **workspaceInBytes** is size in bytes of the working space, and it is returned by **cusolverDnPotrf_bufferSize()**.

If Cholesky factorization failed, i.e. some leading minor of \( A \) is not positive definite, or equivalently some diagonal elements of \( L \) or \( U \) is not a real number. The output
Using the CUSOLVER API

parameter `info` would indicate smallest leading minor of `A` which is not positive definite.

If output parameter `info = -i` (less than zero), the `i-th` parameter is wrong (not counting handle).

Currently, `cusolverDnPotrf` supports only the default algorithm.

**Table of algorithms supported by cusolverDnPotrf**

    int *Lwork );
cusolverStatus_t
 cusolverDnCpotri_bufferSize(cusolverDnHandle_t handle,
    _cublasFillMode_t uplo,
    int n,
    cuComplex *A,
    int lda,
    int *Lwork );
cusolverStatus_t
 cusolverDnZpotri_bufferSize(cusolverDnHandle_t handle,
    _cublasFillMode_t uplo,
    int n,
    cuDoubleComplex *A,
    int lda,
    int *Lwork );

The S and D data types are real valued single and double precision, respectively.

cusolverStatus_t
 cusolverDnSpotri(cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    float *A,
    int lda,
    float *Workspace,
    int Lwork,
    int *devInfo );
cusolverStatus_t
 cusolverDnDpotri(cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    double *A,
    int lda,
    double *Workspace,
    int Lwork,
    int *devInfo );
The C and Z data types are complex valued single and double precision, respectively.

```c
cusolverStatus_t
cusolverDnCpotri(cusolverDnHandle_t handle,
cublasFillMode_t uplo,
int n,
cuComplex *A,
int lda,
cuComplex *Workspace,
int Lwork,
int *devInfo );
```

```c
cusolverStatus_t
cusolverDnZpotri(cusolverDnHandle_t handle,
cublasFillMode_t uplo,
int n,
cuDoubleComplex *A,
int lda,
cuDoubleComplex *Workspace,
int Lwork,
int *devInfo );
```

This function computes the inverse of a positive-definite matrix $A$ using the Cholesky factorization

$$A = L^* L^H = U^H U$$

computed by `potrf()`.

$A$ is a $n \times n$ matrix containing the triangular factor $L$ or $U$ computed by the Cholesky factorization. Only lower or upper part is meaningful and the input parameter `uplo` indicates which part of the matrix is used. The function would leave the other part untouched.

If the input parameter `uplo` is `CUBLAS_FILL_MODE_LOWER`, only lower triangular part of $A$ is processed, and replaced by the lower triangular part of the inverse of $A$.

If the input parameter `uplo` is `CUBLAS_FILL_MODE_UPPER`, only upper triangular part of $A$ is processed, and replaced by the upper triangular part of the inverse of $A$.

The user has to provide the working space which is pointed to by input parameter `Workspace`. The input parameter `Lwork` is the size of the working space, returned by `potri_bufferSize()`.

If the computation of the inverse fails, i.e. some leading minor of $L$ or $U$, is null, the output parameter `devInfo` would indicate the smallest leading minor of $L$ or $U$ which is not positive definite.

If the output parameter `devInfo = -i` (less than zero), the $i$-th parameter is wrong (not counting the handle).

  int m,
  int n,
  cuDoubleComplex *A,
  int lda,
  int *Lwork );
```

The S and D data types are real single and double precision, respectively.

```c
cusolverStatus_t
cusolverDnSgetrf(cusolverDnHandle_t handle,
  int m,
  int n,
  float *A,
  int lda,
  float *Workspace,
  int *devIpiv,
  int *devInfo );

cusolverStatus_t
cusolverDnDgetrf(cusolverDnHandle_t handle,
  int m,
  int n,
  double *A,
  int lda,
  double *Workspace,
  int *devIpiv,
  int *devInfo );
```
The C and Z data types are complex valued single and double precision, respectively.

```c
cusolverStatus_t
cusolverDnCgetrf(cusolverDnHandle_t handle,
    int m,
    int n,
    cuComplex *A,
    int lda,
    cuComplex *Workspace,
    int *devIpiv,
    int *devInfo );
```

```c
cusolverStatus_t
cusolverDnZgetrf(cusolverDnHandle_t handle,
    int m,
    int n,
    cuDoubleComplex *A,
    int lda,
    cuDoubleComplex *Workspace,
    int *devIpiv,
    int *devInfo );
```

This function computes the LU factorization of a \(m \times n\) matrix

\[ P^*A = L^*U \]

where \(A\) is a \(m \times n\) matrix, \(P\) is a permutation matrix, \(L\) is a lower triangular matrix with unit diagonal, and \(U\) is an upper triangular matrix.

The user has to provide working space which is pointed by input parameter \(\text{Workspace}\). The input parameter \(\text{Lwork}\) is size of the working space, and it is returned by \(\text{getrf_bufferSize()}\).

If LU factorization failed, i.e. matrix \(A\) (\(U\)) is singular, The output parameter \(\text{devInfo}=i\) indicates \(U(i,i) = 0\).

If output parameter \(\text{devInfo} = -i\) (less than zero), the \(i\)-th parameter is wrong (not counting handle).

If \(\text{devIpiv}\) is null, no pivoting is performed. The factorization is \(A=L^*U\), which is not numerically stable.

No matter LU factorization failed or not, the output parameter \(\text{devIpiv}\) contains pivoting sequence, row \(i\) is interchanged with row \(\text{devIpiv}(i)\).

The user can combine \(\text{getrf}\) and \(\text{getrs}\) to complete a linear solver. Please refer to appendix D.1.

Remark: \(\text{getrf}\) uses fastest implementation with large workspace of size \(m^*n\). The user can choose the legacy implementation with minimal workspace by \(\text{Getrf}\) and \(\text{cusolverDnSetAdvOptions(params, CUSOLVERDN_GETRF, CUSOLVER_ALG_1)}\).

#### 2.4.2.7. `cusolverDnGetrf()`

The helper function below can calculate the sizes needed for pre-allocated buffer.

```c
cusolverStatus_t
cusolverDnGetrf_bufferSize(
    cusolverDnHandle_t handle,
    cusolverDnParams_t params,
    int64_t m,
    int64_t n,
    cudaDataType dataTypeA,
    const void *A,
    int64_t lda,
    cudaDataType computeType,
    size_t *workspaceInBytes )
```
The function below

```c
  cusolverStatus_t
  cusolverDnGetrf(
    cusolverDnHandle_t handle,
    cusolverDnParams_t params,
    int64_t m,
    int64_t n,
    cudaDataType dataTypeA,
    void *A,
    int64_t lda,
    int64_t *ipiv,
    cudaDataType computeType,
    void *pBuffer,
    size_t workspaceInBytes,
    int *info )
```

computes the LU factorization of a \( m \times n \) matrix

\[
P*A = L*U
\]

where \( A \) is a \( m \times n \) matrix, \( P \) is a permutation matrix, \( L \) is a lower triangular matrix with unit diagonal, and \( U \) is an upper triangular matrix using the generic API interface.

If LU factorization failed, i.e. matrix \( A \) (U) is singular, The output parameter \( info = i \) indicates \( U(i,i) = 0 \).

If output parameter \( info = -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle).

If \( ipiv \) is null, no pivoting is performed. The factorization is \( A = L*U \), which is not numerically stable.

No matter LU factorization failed or not, the output parameter \( ipiv \) contains pivoting sequence, row \( i \) is interchanged with row \( ipiv(i) \).

The user has to provide working space which is pointed by input parameter \( pBuffer \). The input parameter \( workspaceInBytes \) is size in bytes of the working space, and it is returned by \( cusolverDnGetrf_bufferSize() \).

The user can combine \( cusolverDnGetrf \) and \( cusolverDnGetrs \) to complete a linear solver.

Currently, \( cusolverDnGetrf \) supports two algorithms. To select legacy implementation, the user has to call \( cusolverDnSetAdvOptions \).

**Table of algorithms supported by cusolverDnGetrf**

2.4.2.8. cusolverDn<t>getrs()

```c
 cusolverStatus_t
cusolverDnSgetrs(cusolverDnHandle_t handle,
                 cublasOperation_t trans,
                 int n,
                 int nrhs,
                 const float *A,
                 int lda,
                 const int *devIpiv,
                 float *B,
                 int ldb,
                 int *devInfo );

 cusolverStatus_t
cusolverDnDgetrs(cusolverDnHandle_t handle,
                 cublasOperation_t trans,
                 int n,
                 int nrhs,
                 const double *A,
                 int lda,
                 const int *devIpiv,
                 double *B,
                 int ldb,
                 int *devInfo );

 cusolverStatus_t
cusolverDnCgetrs(cusolverDnHandle_t handle,
                 cublasOperation_t trans,
                 int n,
                 int nrhs,
                 const cuComplex *A,
                 int lda,
                 const int *devIpiv,
                 cuComplex *B,
                 int ldb,
                 int *devInfo );

 cusolverStatus_t
cusolverDnZgetrs(cusolverDnHandle_t handle,
                 cublasOperation_t trans,
                 int n,
                 int nrhs,
                 const cuDoubleComplex *A,
                 int lda,
                 const int *devIpiv,
                 cuDoubleComplex *B,
                 int ldb,
                 int *devInfo );
```

This function solves a linear system of multiple right-hand sides

\[ \text{op}(A)X = B \]
where \( A \) is a \( n \times n \) matrix, and was LU-factored by \texttt{getrf}, that is, lower triangular part of \( A \) is \( L \), and upper triangular part (including diagonal elements) of \( A \) is \( U \). \( B \) is a \( n \times nrhs \) right-hand side matrix.

The input parameter \texttt{trans} is defined by

\[
\text{op}(A) = \begin{cases} 
A & \text{if } \text{trans} == \text{CUBLAS\_OP\_N} \\
A^T & \text{if } \text{trans} == \text{CUBLAS\_OP\_T} \\
A^H & \text{if } \text{trans} == \text{CUBLAS\_OP\_C}
\end{cases}
\]

The input parameter \texttt{devIpiv} is an output of \texttt{getrf}. It contains pivot indices, which are used to permute right-hand sides.

If output parameter \texttt{devInfo} = -i (less than zero), the i-th parameter is wrong (not counting handle).

The user can combine \texttt{getrf} and \texttt{getrs} to complete a linear solver. Please refer to appendix D.1.

2.4.2.10. `cusolverDn<t1><t2>gesv()`

These functions are modelled after functions DSGESV and ZCGESV from LAPACK. They compute the solution of a system of linear equations with one or multiple right hand sides using mixed precision iterative refinement techniques based on the LU factorization Xgesv. These functions are similar in term of functionalities to the full
precision LU solver (Xgesv, where X denotes Z,C,D,S) but it uses lower precision internally in order to provide faster time to solution, from here came the name mixed precision. Mixed precision iterative refinement techniques means that the solver compute an LU factorization in lower precision and then iteratively refine the solution to achieve the accuracy of the Inputs/Outputs datatype precision. The <t1> corresponds to the Inputs/Outputs datatype precision while <t2> represent the internal lower precision at which the factorization will be carried on.

\[ A \times X = B \]

Where \( A \) is \( n \)-by-\( n \) matrix and \( X \) and \( B \) are \( n \)-by-\( nrhs \) matrices.

Functions API are designed to be as close as possible to LAPACK API to be considered as a quick and easy drop-in replacement. Parameters and behavior are mostly the same as LAPACK counterparts. Description of these functions and differences from LAPACK is given below. <t1><t2>gesv() functions are designated by two floating point precisions The <t1> corresponds to the main precision (e.g., Inputs/Outputs datatype precision) and the <t2> represent the internal lower precision at which the factorization will be carried on. cusolver<t1><t2>gesv() first attempts to factorize the matrix in lower precision and use this factorization within an iterative refinement procedure to obtain a solution with same normwise backward error as the main precision <t1>. If the approach fails to converge, then the method fallback to the main precision factorization and solve (Xgesv) such a way that there is always a good solution at the output of these functions. If <t2> is equal to <t1>, then it is not a mixed precision process but rather a full one precision factorisation, solve and refinement within the same main precision.

The iterative refinement process is stopped if

```
ITER > ITERMAX
```

or for all the RHS we have:

\[ RNRM < \sqrt{N} \times XNRM \times ANRM \times EPS \times BWDMAX \]

where

- ITER is the number of the current iteration in the iterative refinement process
- RNRM is the infinity-norm of the residual
- XNRM is the infinity-norm of the solution
- ANRM is the infinity-operator-norm of the matrix A
- EPS is the machine epsilon that matches LAPACK <t1>LAMCH('Epsilon')

The value ITERMAX and BWDMAX are fixed to 50 and 1.0 respectively.

The function returns value describes the results of the solving process. A CUSOLVER_STATUS_SUCCESS indicates that the function finished with success otherwise, it indicates if one of the API arguments is incorrect, or if the function did not finish with success. More details about the error will be in the niters and the dinfo API parameters. See their description below for more details. User should provide the required workspace allocated on device memory. The amount of bytes required can be queried by calling the respective function <t1><t2>gesv_bufferSize().
Note that in addition to the two mixed precision functions available in LAPACK (e.g., dsgesv and zcgesv), we provide a large set of mixed precision functions that include half, bfloat and tensorfloat as a lower precision as well as same precision functions (e.g., main and lowest precision are equal &t2 is equal to &t1). The following table specifies which precisions will be used for which interface function.

Tensor Float (TF32), introduced with NVIDIA Ampere Architecture GPUs, is the most robust tensor core accelerated compute mode for the iterative refinement solver. It is able to solve the widest range of problems in HPC arising from different applications and provides up to 4X and 5X speedup for real and complex systems, respectively. On Volta and Turing architecture GPUs, half precision tensor core acceleration is recommended. In cases where the iterative refinement solver fails to converge to the desired accuracy (main precision, INOUT data precision), it is recommended to use main precision as internal lowest precision (i.e., cusolverDn[DD, ZZ]gesv for the FP64 case).

#### 2.4.2.11. cusolverDnIRSXgesv()

This function is designed to perform same functionality as cusolverDn<T1><T2>gesv() functions, but wrapped in a more generic and expert interface that gives user more control to parametrize the function as well as it provides more informations on output. cusolverDnIRSXgesv() allows additional control of the solver parameters such as setting:

- the main precision (Inputs/Outputs precision) of the solver,
- the lowest precision to be used internally by the solver,
- the refinement solver type,
- the maximum allowed number of iterations in the refinement phase,
- the tolerance of the refinement solver,
the fallback to main precision,
and more other.

through the configuration parameters structure gesv_irs_params and its helper
functions. For more details about what configuration can be set and its meaning
please refer to all the functions in the cuSolverDN Helper Function Section that start
with `cusolverDnIRSParamsxxxx()` . Moreover, `cusolverDnIRSXgesv()` provides
additional informations on the output such as the convergence history (e.g., the
residual norms) at each iteration and the number of iterations needed to converge.
For more details about what informations can be retrieved and its meaning please
refer to all the functions in the cuSolverDN Helper Function Section that start with
`cusolverDnIRSInfosxxxx()`.

The function returns value describes the results of the solving process. A
CUSOLVER_STATUS_SUCCESS indicates that the function finished with success
otherwise, it indicates if one of the API arguments is incorrect, or if the configurations
of params/infos structure is incorrect or if the function did not finish with success.
More details about the error can be found by checking the `niter` and the `dinfo` API
parameters. See their description below for further details. User should provide the
required workspace allocated on device for the `cusolverDnIRSXgesv()` function. The
amount of bytes required for the function can be queried by calling the respective
function `cusolverDnIRSXgesv_bufferSize()` . Note that, if the user would like a pratical
configuration to be set via the params structure, it should be set before the call to
cusolverDnIRSXgesv_bufferSize() to get the size of the required workspace.

Tensor Float (TF32), introduced with NVIDIA Ampere Architecture GPUs, is the most
robust tensor core accelerated compute mode for the iterative refinement solver. It is able
to solve the widest range of problems in HPC arising from different applications and
provides up to 4X and 5X speedup for real and complex systems, respectively. On Volta
and Turing architecture GPUs, half precision tensor core acceleration is recommended.
In cases where the iterative refinement solver fails to converge to the desired accuracy
(main precision, INOUT data precision), it is recommended to use main precision as
internal lowest precision.

The following table provides all possible combinations values for the lowest precision
corresponding to the Inputs/Outputs data type. Note that if the lowest precision matches
the Inputs/Outputs datatype, then the main precision factorization will be used.

<table>
<thead>
<tr>
<th>Supported Inputs/Outputs data type and lower precision for the IRS solver</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Inputs/Outputs Data Type (e.g., main precision)</strong></td>
</tr>

<td>CUSOLVER_R_32F</td>
</tr>
</tbody>
</table>
The `cusolverDnIRSXgesv_bufferSize()` function returns the required workspace buffer size in bytes for the corresponding `cusolverDnXgesv()` call with the given `gesv_irs_params` configuration.

```c
 cusolverStatus_t
 cusolverDnIRSXgesv_bufferSize(
     cusolverDnHandle_t          handle,
     cusolverDnIRSParams_t       gesv_irs_params,
     cusolver_int_t              n,
     cusolver_int_t              nrhs,
     size_t                   *   lwork_bytes);
```

2.4.2.12. cusolverDn<t>geqrf()

These helper functions calculate the size of work buffers needed.

```c
 cusolverStatus_t
cusolverDnSgeqrf_bufferSize(cusolverDnHandle_t handle,
               int m,
               int n,
               float *A,
               int lda,
               int *Lwork );

cusolverStatus_t
cusolverDnDgeqrf_bufferSize(cusolverDnHandle_t handle,
               int m,
               int n,
               double *A,
               int lda,
               int *Lwork );

cusolverStatus_t
cusolverDnCgeqrf_bufferSize(cusolverDnHandle_t handle,
               int m,
               int n,
               cuComplex *A,
               int lda,
               int *Lwork );

cusolverStatus_t
cusolverDnZgeqrf_bufferSize(cusolverDnHandle_t handle,
               int m,
               int n,
               cuDoubleComplex *A,
               int lda,
               int *Lwork );
```

The S and D data types are real valued single and double precision, respectively.

```c
 cusolverStatus_t
cusolverDnSgeqrf(cusolverDnHandle_t handle,
               int m,
               int n,
               float *A,
               int lda,
               float *TAU,
               float *Workspace,
               int Lwork,
               int *devInfo );

cusolverStatus_t
cusolverDnDgeqrf(cusolverDnHandle_t handle,
               int m,
               int n,
               double *A,
               int lda,
               double *TAU,
               double *Workspace,
               int Lwork,
               int *devInfo );
```
The C and Z data types are complex valued single and double precision, respectively.

cusolverStatus_t
cusolverDnCgeqrf(cusolverDnHandle_t handle,
    int m,
    int n,
    cuComplex *A,
    int lda,
    cuComplex *TAU,
    cuComplex *Workspace,
    int Lwork,
    int *devInfo );

cusolverStatus_t
cusolverDnZgeqrf(cusolverDnHandle_t handle,
    int m,
    int n,
    cuDoubleComplex *A,
    int lda,
    cuDoubleComplex *TAU,
    cuDoubleComplex *Workspace,
    int Lwork,
    int *devInfo );

This function computes the QR factorization of a \( m \times n \) matrix 

\[ A = Q \cdot R \]

where \( A \) is a \( m \times n \) matrix, \( Q \) is a \( m \times n \) matrix, and \( R \) is a \( n \times n \) upper triangular matrix.

The user has to provide working space which is pointed by input parameter **Workspace**. The input parameter **Lwork** is size of the working space, and it is returned by **geqrf_bufferSize()**.

The matrix \( R \) is overwritten in upper triangular part of \( A \), including diagonal elements.

The matrix \( Q \) is not formed explicitly, instead, a sequence of householder vectors are stored in lower triangular part of \( A \). The leading nonzero element of householder vector is assumed to be 1 such that output parameter **TAU** contains the scaling factor \( \tau \). If \( v \) is original householder vector, \( q \) is the new householder vector corresponding to \( \tau \), satisying the following relation

\[ I - 2v^*vH = I - \tau^*q^*qH \]

If output parameter **devInfo** = \(-i\) (less than zero), the \( i\)-th parameter is wrong (not counting handle).

### 2.4.2.13. cusolverDnGeqrf()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
cusolverStatus_t
cusolverDnGeqrf_bufferSize(
    cusolverDnHandle_t handle,
    cusolverDnParams_t params,
    int64_t m,
    int64_t n,
    cudaDataType dataTypeA,
    const void *A,
    int64_t lda,
    cudaDataType dataTypeTau,
    const void *tau,
    cudaDataType computeType,
    size_t *workspaceInBytes )
```

---

www.nvidia.com
cuSOLVER Library
DU-06709-001_v11.0 | 74
The routine below

```c
 cusolverStatus_t
cusolverDnGeqrf(
    cusolverDnHandle_t handle,
    cusolverDnParams_t params,
    int64_t m,
    int64_t n,
    cudaDataType dataTypeA,
    void *A,
    int64_t lda,
    cudaDataType dataTypeTau,
    void *tau,
    cudaDataType computeType,
    void *pBuffer,
    size_t workspaceInBytes,
    int *info )
```

computes the QR factorization of a \( m \times n \) matrix

\[
A = QR
\]

where \( A \) is a \( m \times n \) matrix, \( Q \) is a \( m \times n \) matrix, and \( R \) is a \( n \times n \) upper triangular matrix using the generic API interface.

The user has to provide working space which is pointed by input parameter \( pBuffer \). The input parameter \( workspaceInBytes \) is size in bytes of the working space, and it is returned by \( \text{cusolverDnGeqrf\_bufferSize()} \).

The matrix \( R \) is overwritten in upper triangular part of \( A \), including diagonal elements.

The matrix \( Q \) is not formed explicitly, instead, a sequence of householder vectors are stored in lower triangular part of \( A \). The leading nonzero element of householder vector is assumed to be 1 such that output parameter \( \text{TAU} \) contains the scaling factor \( \tau \). If \( v \) is original householder vector, \( q \) is the new householder vector corresponding to \( \tau \), satisfying the following relation

\[
I - 2v^*v = I - 2\tau^*q^*q^H
\]

If output parameter \( info = -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle).

Currently, \( \text{cusolverDnGeqrf} \) supports only the default algorithm.

Table of algorithms supported by \( \text{cusolverDnGeqrf} \)

### 2.4.2.14. `cusolverDn<t1><t2>gels()`

These functions compute the solution of a system of linear equations with one or multiple right hand sides using mixed precision iterative refinement techniques based on the QR factorization Xgels. These functions are similar in term of functionalities to the full precision LAPACK QR (least squares) solver (Xgels, where X denotes Z,C,D,S) but it uses lower precision internally in order to provide faster time to solution, from here comes the name mixed precision. Mixed precision iterative refinement techniques means that the solver compute an QR factorization in lower precision and then iteratively refine
the solution to achieve the accuracy of the Inputs/Outputs datatype precision. The \(<t1>\) corresponds to the Inputs/Outputs datatype precision while \(<t2>\) represent the internal lower precision at which the factorization will be carried on.

\[
A \times X = B
\]

Where \(A\) is \(m\)-by-\(n\) matrix and \(X\) is \(n\)-by-\(nrhs\) and \(B\) is \(m\)-by-\(nrhs\) matrices.

Functions API are designed to be as close as possible to LAPACK API to be considered as a quickand easy drop-in replacement. Description of these functions is given below. \(<t1><t2>gels()\) functions are designated by two floating point precisions The \(<t1>\) corresponds to the main precision (e.g., Inputs/Outputs datatype precision) and the \(<t2>\) represent the internal lower precision at which the factorization will be carried on. \(\text{cusolver}<t1><t2>gels()\) first attempts to factorize the matrix in lower precision and use this factorization within an iterative refinement procedure to obtain a solution with same normwise backward error as the main precision \(<t1>\). If the approach fails to converge, then the method fallback to the main precision factorization and solve (Xgels) such a way that there is always a good solution at the output of these functions. If \(<t2>\) is equal to \(<t1>\), then it is not a mixed precision process but rather a full one precision factorisation, solve and refinement within the same main precision.

The iterative refinement process is stopped if

\[
\text{ITER} > \text{ITERMAX}
\]

or for all the RHS we have:

\[
\text{RNRM} < \sqrt{N} \times \text{XNRM} \times \text{ANRM} \times \text{EPS} \times \text{BWDMAX}
\]

where

- \(\text{ITER}\) is the number of the current iteration in the iterative refinement process
- \(\text{RNRM}\) is the infinity-norm of the residual
- \(\text{XNRM}\) is the infinity-norm of the solution
- \(\text{ANRM}\) is the infinity-operator-norm of the matrix \(A\)
- \(\text{EPS}\) is the machine epsilon that matches LAPACK \(<t1>\text{LAMCH('Epsilon')}\)

The value \(\text{ITERMAX}\) and \(\text{BWDMAX}\) are fixed to 50 and 1.0 respectively.

The function returns value describes the results of the solving process. A \(\text{CUSOLVER\_STATUS\_SUCCESS}\) indicates that the function finished with success otherwise, it indicates if one of the API arguments is incorrect, or if the function did not finish with success. More details about the error will be in the \text{niters} and the \text{dinfo} API parameters. See their description below for more details. User should provide the required workspace allocated on device memory. The amount of bytes required can be queried by calling the respective function \(<t1><t2>gels\_bufferSize()\).

We provide a large set of mixed precision functions that include half, bfloat and tensorflow as a lower precision as well as same precision functions (e.g., main and lowest precision are equal \(<t2>\) is equal to \(<t1>\)). The following table specifies which precisions will be used for which interface function:
Tensor Float (TF32), introduced with NVIDIA Ampere Architecture GPUs, is the most robust tensor core accelerated compute mode for the iterative refinement solver. It is able to solve the widest range of problems in HPC arising from different applications and provides up to 4X and 5X speedup for real and complex systems, respectively. On Volta and Turing architecture GPUs, half precision tensor core acceleration is recommended. In cases where the iterative refinement solver fails to converge to the desired accuracy (main precision, INOUT data precision), it is recommended to use main precision as internal lowest precision (i.e., \texttt{cusolverDn[DD,ZZ]gels} for the FP64 case).

**Supported combinations of floating point precisions for cusolver \texttt{<t1><t2>gels()} functions**

### 2.4.2.15. cusolverDnIRSXgels()

This function is designed to perform same functionality as cusolverDn<T1><T2>gels() functions, but wrapped in a more generic and expert interface that gives user more control to parametrize the function as well as it provides more informations on output. cusolverDnIRSXgels() allows additional control of the solver parameters such as setting:

- the main precision (Inputs/Outputs precision) of the solver,
- the lowest precision to be used internally by the solver,
- the refinement solver type,
- the maximum allowed number of iterations in the refinement phase,
- the tolerance of the refinement solver,
- the fallback to main precision,
- and more other.

through the configuration parameters structure gels_irs_params and its helper functions. For more details about what configuration can be set and its meaning please refer to all the functions in the cuSolverDN Helper Function Section that start with cusolverDnIRSParamsxxxx() . Moreover, cusolverDnIRSXgels() provides additional
informations on the output such as the convergence history (e.g., the residual norms) at each iteration and the number of iterations needed to converge. For more details about what informations can be retrieved and its meaning please refer to all the functions in the cuSolverDN Helper Function Section that start with `cusolverDnIRSInfosxxxx()`.

The function returns value describes the results of the solving process. A `CUSOLVER_STATUS_SUCCESS` indicates that the function finished with success otherwise, it indicates if one of the API arguments is incorrect, or if the configurations of params/infos structure is incorrect or if the function did not finish with success. More details about the error can be found by checking the `niter` and the `dinfo` API parameters. See their description below for further details. User should provide the required workspace allocated on device for the `cusolverDnIRSXgels()` function. The amount of bytes required for the function can be queried by calling the respective function `cusolverDnIRSXgels_bufferSize()`. Note that, if the user would like a particular configuration to be set via the params structure, it should be set before the call to `cusolverDnIRSXgels_bufferSize()` to get the size of the required workspace.

The following table provides all possible combinations values for the lowest precision corresponding to the Inputs/Outputs data type. Note that if the lowest precision matches the Inputs/Outputs datatype, then main precision factorization will be used.

Tensor Float (TF32), introduced with NVIDIA Ampere Architecture GPUs, is the most robust tensor core accelerated compute mode for the iterative refinement solver. It is able to solve the widest range of problems in HPC arising from different applications and provides up to 4X and 5X speedup for real and complex systems, respectively. On Volta and Turing architecture GPUs, half precision tensor core acceleration is recommended. In cases where the iterative refinement solver fails to converge to the desired accuracy (main precision, INOUT data precision), it is recommended to use main precision as internal lowest precision.

**Supported Inputs/Outputs data type and lower precision for the IRS solver**

</table>
The cusolverDnIRSxgels_bufferSize() function returns the required workspace buffer size in bytes for the corresponding cusolverDnXgels() call with given gels_irs_params configuration.

```c
cusolverStatus_t cusolverDnIRSxgels_bufferSize(
    cusolverDnHandle_t          handle,
    cusolverDnIRSParams_t       gels_irs_params,
    cusolver_int_t              m,
    cusolver_int_t              n,
    cusolver_int_t              nrhs,
    size_t                  *   lwork_bytes);
```

    int *devInfo);
Using the CUSOLVER API

The C and Z data types are complex valued single and double precision, respectively.

cusolverStatus_t
cusolverDnCunmqr(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    cublasOperation_t trans,
    int m,
    int n,
    int k,
    const cuComplex *A,
    int lda,
    const cuComplex *tau,
    cuComplex *C,
    int ldc,
    cuComplex *work,
    int lwork,
    int *devInfo);

cusolverStatus_t
cusolverDnZunmqr(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    cublasOperation_t trans,
    int m,
    int n,
    int k,
    const cuDoubleComplex *A,
    int lda,
    const cuDoubleComplex *tau,
    cuDoubleComplex *C,
    int ldc,
    cuDoubleComplex *work,
    int lwork,
    int *devInfo);

This function overwrites $m \times n$ matrix $C$ by

$$C = \begin{cases} 
\text{op}(Q)C & \text{if side} == \text{CUBLAS\_SIDE\_LEFT} \\
C\text{op}(Q) & \text{if side} == \text{CUBLAS\_SIDE\_RIGHT} 
\end{cases}$$

The operation of $Q$ is defined by

$$\text{op}(Q) = \begin{cases} 
Q & \text{if transa} == \text{CUBLAS\_OP\_N} \\
Q^T & \text{if transa} == \text{CUBLAS\_OP\_T} \\
Q^H & \text{if transa} == \text{CUBLAS\_OP\_C} 
\end{cases}$$

$Q$ is a unitary matrix formed by a sequence of elementary reflection vectors from QR factorization ($\text{geqrf}$) of $A$.

$Q = H(1) H(2) ... H(k)$

$Q$ is of order $m$ if $\text{side} = \text{CUBLAS\_SIDE\_LEFT}$ and of order $n$ if $\text{side} = \text{CUBLAS\_SIDE\_RIGHT}$. 
The user has to provide working space which is pointed by input parameter `work`. The input parameter `lwork` is size of the working space, and it is returned by `geqrf_bufferSize()` or `ormqr_bufferSize()`.

If output parameter `devInfo = -i` (less than zero), the `i`-th parameter is wrong (not counting handle).

The user can combine `geqrf`, `ormqr` and `trsm` to complete a linear solver or a least-square solver. Please refer to appendix C.1.

This function overwrites \( m \times n \) matrix \( \mathbf{A} \) by
where $Q$ is a unitary matrix formed by a sequence of elementary reflection vectors stored in $A$.

The user has to provide working space which is pointed by input parameter $work$. The input parameter $lwork$ is size of the working space, and it is returned by orgqr_bufferSize().

If output parameter $devInfo = -i$ (less than zero), the $i$-th parameter is wrong (not counting handle).

The user can combine $\text{geqrf, orgqr}$ to complete orthogonalization. Please refer to appendix C.2.

cusolverDnZsytrf_bufferSize(cusolverDnHandle_t handle,
    int n,
    cuDoubleComplex *A,
    int lda,
    int *Lwork );
```

The S and D data types are real valued single and double precision, respectively.

```c
cusolverStatus_t
cusolverDnSsytrf(cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    float *A,
    int lda,
    int *ipiv,
    float *work,
    int lwork,
    int *devInfo );

cusolverStatus_t
cusolverDnDsytrf(cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    double *A,
    int lda,
    int *ipiv,
    double *work,
    int lwork,
    int *devInfo );
```
The C and Z data types are complex valued single and double precision, respectively.

```c
cusolverStatus_t cusolverDnCsytrf(cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    cuComplex *A,
    int lda,
    int *ipiv,
    cuComplex *work,
    int lwork,
    int *devInfo );

cusolverStatus_t cusolverDnZsytrf(cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    cuDoubleComplex *A,
    int lda,
    int *ipiv,
    cuDoubleComplex *work,
    int lwork,
    int *devInfo );
```

This function computes the Bunch-Kaufman factorization of a $n\times n$ symmetric indefinite matrix

$A$ is a $n\times n$ symmetric matrix, only lower or upper part is meaningful. The input parameter $uplo$ which part of the matrix is used. The function would leave other part untouched.

If input parameter $uplo$ is CUBLAS_FILL_MODE_LOWER, only lower triangular part of $A$ is processed, and replaced by lower triangular factor $L$ and block diagonal matrix $D$. Each block of $D$ is either 1x1 or 2x2 block, depending on pivoting.

$$P^*A^*P^T=L^*D^*L^T$$

If input parameter $uplo$ is CUBLAS_FILL_MODE_UPPER, only upper triangular part of $A$ is processed, and replaced by upper triangular factor $U$ and block diagonal matrix $D$.

$$P^*A^*P^T=U^*D^*U^T$$

The user has to provide working space which is pointed by input parameter $work$. The input parameter $lwork$ is size of the working space, and it is returned by $\text{sytrf_bufferSize}()$.

If Bunch-Kaufman factorization failed, i.e. $A$ is singular. The output parameter $devInfo = i$ would indicate $D(i,i)=0$.

If output parameter $devInfo = -i$ (less than zero), the $i$-th parameter is wrong (not counting handle).

The output parameter $\text{devIpiv}$ contains pivoting sequence. If $\text{devIpiv}(i) = k > 0$, $D(i,i)$ is 1x1 block, and $i$-th row/column of $A$ is interchanged with $k$-th row/column of $A$. If $uplo$ is CUBLAS_FILL_MODE_UPPER and $\text{devIpiv}(i-1) = \text{devIpiv}(i) = -m < 0$, $D(i-1:i,i-1:i)$ is a 2x2 block, and $(i-1)$-th row/column is interchanged.
with \(m\)-th row/column. If \(\text{uplo}\) is \text{CUBLAS_FILL_MODE_LOWER} and \(\text{devIpiv}(i+1) = \text{devIpiv}(i) = -m < 0, D(i:i+1,i:i+1)\) is a 2x2 block, and \((i+1)\)-th row/column is interchanged with \(m\)-th row/column.

2.4.2.19. `cusolverDn<t>potrfBatched()`

The S and D data types are real valued single and double precision, respectively.

```c
cusolverStatus_t
cusolverDnSpotrfBatched(
    cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    float *Aarray[],
    int lda,
    int *infoArray,
    int batchSize);

cusolverStatus_t
cusolverDnDpotrfBatched(
    cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    double *Aarray[],
    int lda,
    int *infoArray,
    int batchSize);
```

The C and Z data types are complex valued single and double precision, respectively.

```c
cusolverStatus_t
cusolverDnCpotrfBatched(
    cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    cuComplex *Aarray[],
    int lda,
    int *infoArray,
    int batchSize);

cusolverStatus_t
cusolverDnZpotrfBatched(
    cusolverDnHandle_t handle,
    cublasFillMode_t uplo,
    int n,
    cuDoubleComplex *Aarray[],
    int lda,
    int *infoArray,
    int batchSize);
```

This function computes the Cholesky factorization of a sequence of Hermitian positive-definite matrices.

Each `Aarray[i] for i=0,1,..., batchSize-1` is an `n x n` Hermitian matrix, only lower or upper part is meaningful. The input parameter `uplo` indicates which part of the matrix is used.

If input parameter `uplo` is `CUBLAS_FILL_MODE_LOWER`, only lower triangular part of `A` is processed, and replaced by lower triangular Cholesky factor `L`.

\[ A = L \cdot L^H \]
If input parameter \texttt{uplo} is \texttt{CUBLAS\_FILL\_MODE\_UPPER}, only upper triangular part of \(A\) is processed, and replaced by upper triangular Cholesky factor \(U\).

\[ A = U^H U \]

If Cholesky factorization failed, i.e. some leading minor of \(A\) is not positive definite, or equivalently some diagonal elements of \(L\) or \(U\) is not a real number. The output parameter \texttt{infoArray} would indicate smallest leading minor of \(A\) which is not positive definite.

\texttt{infoArray} is an integer array of size \texttt{batchsize}. If \texttt{potrfBatched} returns \texttt{CUSOLVER\_STATUS\_INVALID\_VALUE}, \texttt{infoArray}[0] = -i (less than zero), meaning that the \texttt{i-th} parameter is wrong (not counting handle). If \texttt{potrfBatched} returns \texttt{CUSOLVER\_STATUS\_SUCCESS} but \texttt{infoArray}[i] = k is positive, then \texttt{i-th} matrix is not positive definite and the Cholesky factorization failed at row \(k\).

Remark: the other part of \(A\) is used as a workspace. For example, if \texttt{uplo} is \texttt{CUBLAS\_FILL\_MODE\_UPPER}, upper triangle of \(A\) contains cholesky factor \(U\) and lower triangle of \(A\) is destroyed after \texttt{potrfBatched}.

2.4.2.20. **cusolverDn<t>potrsBatched()**

cusolverStatus_t
cusolverDnSpotrsBatched(
cusolverDnHandle_t handle,
cublasFillMode_t uplo,
int n,
int nrhs,
float *Aarray[],
int lda,
float *Barray[],
int ldb,
int *info,
int batchSize);

cusolverStatus_t
cusolverDnDpotrsBatched(
cusolverDnHandle_t handle,
cublasFillMode_t uplo,
int n,
int nrhs,
double *Aarray[],
int lda,
double *Barray[],
int ldb,
int *info,
int batchSize);

cusolverStatus_t
cusolverDnCpotrsBatched(
cusolverDnHandle_t handle,
cublasFillMode_t uplo,
int n,
int nrhs,
cuComplex *Aarray[],
int lda,
cuComplex *Barray[],
int ldb,
int *info,
int batchSize);

cusolverStatus_t
cusolverDnZpotrsBatched(
cusolverDnHandle_t handle,
cublasFillMode_t uplo,
int n,
int nrhs,
cuDoubleComplex *Aarray[],
int lda,
cuDoubleComplex *Barray[],
int ldb,
int *info,
int batchSize);
This function solves a sequence of linear systems

\[ A[i]X[i] = B[i] \]

where each \( A[i] \) for \( i=0,1,\ldots, \text{batchSize}-1 \) is an \( n \times n \) Hermitian matrix, only lower or upper part is meaningful. The input parameter \( \text{uplo} \) indicates which part of the matrix is used.

The user has to call \texttt{potrfBatched} first to factorize matrix \( A[i] \). If input parameter \( \text{uplo} \) is \texttt{CUBLAS_FILL_MODE_LOWER}, \( A \) is lower triangular Cholesky factor \( L \) corresponding to \( A = L^*L^H \). If input parameter \( \text{uplo} \) is \texttt{CUBLAS_FILL_MODE_UPPER}, \( A \) is upper triangular Cholesky factor \( U \) corresponding to \( A = U^*U \).

The operation is in-place, i.e. matrix \( X \) overwrites matrix \( B \) with the same leading dimension \( \text{ldb} \).

The output parameter \( \text{info} \) is a scalar. If \( \text{info} = -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle).

Remark 1: only \( \text{nrhs}=1 \) is supported.

Remark 2: \( \text{infoArray} \) from \texttt{potrfBatched} indicates if the matrix is positive definite. \( \text{info} \) from \texttt{potrsBatched} only shows which input parameter is wrong (not counting handle).

Remark 3: the other part of \( A \) is used as a workspace. For example, if \( \text{uplo} \) is \texttt{CUBLAS_FILL_MODE_UPPER}, upper triangle of \( A \) contains Cholesky factor \( U \) and lower triangle of \( A \) is destroyed after \texttt{potrsBatched}.

2.4.3. Dense Eigenvalue Solver Reference

This chapter describes eigenvalue solver API of cuSolverDN, including bidiagonalization and SVD.

2.4.3.1. cusolverDn<t>gebrd()

These helper functions calculate the size of work buffers needed.

```c
cusolverStatus_t
cusolverDnSgebrd_bufferSize(
    cusolverDnHandle_t handle,
    int m,
    int n,
    int *Lwork );

cusolverStatus_t
cusolverDnDgebrd_bufferSize(
    cusolverDnHandle_t handle,
    int m,
    int n,
    int *Lwork );

cusolverStatus_t
cusolverDnCgebrd_bufferSize(
    cusolverDnHandle_t handle,
    int m,
    int n,
    int *Lwork );

cusolverStatus_t
cusolverDnZgebrd_bufferSize(
    cusolverDnHandle_t handle,
    int m,
    int n,
    int *Lwork );
```
The S and D data types are real valued single and double precision, respectively.

cusolverStatus_t
cusolverDnSgebrd(cusolverDnHandle_t handle,
    int m,
    int n,
    float *A,
    int lda,
    float *D,
    float *E,
    float *TAUQ,
    float *TAUP,
    float *Work,
    int Lwork,
    int *devInfo );

cusolverStatus_t
cusolverDnDgebrd(cusolverDnHandle_t handle,
    int m,
    int n,
    double *A,
    int lda,
    double *D,
    double *E,
    double *TAUQ,
    double *TAUP,
    double *Work,
    int Lwork,
    int *devInfo );

The C and Z data types are complex valued single and double precision, respectively.

cusolverStatus_t
cusolverDnCgebrd(cusolverDnHandle_t handle,
    int m,
    int n,
    cuComplex *A,
    int lda,
    float *D,
    float *E,
    cuComplex *TAUQ,
    cuComplex *TAUP,
    cuComplex *Work,
    int Lwork,
    int *devInfo );

cusolverStatus_t
cusolverDnZgebrd(cusolverDnHandle_t handle,
    int m,
    int n,
    cuDoubleComplex *A,
    int lda,
    double *D,
    double *E,
    cuDoubleComplex *TAUQ,
    cuDoubleComplex *TAUP,
    cuDoubleComplex *Work,
    int Lwork,
    int *devInfo );
This function reduces a general $m \times n$ matrix $A$ to a real upper or lower bidiagonal form $B$ by an orthogonal transformation: $Q^H \ast A \ast P = B$

If $m \geq n$, $B$ is upper bidiagonal; if $m < n$, $B$ is lower bidiagonal.

The matrix $Q$ and $P$ are overwritten into matrix $A$ in the following sense:

if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix $B$; the elements below the diagonal, with the array $TAUQ$, represent the orthogonal matrix $Q$ as a product of elementary reflectors, and the elements above the first superdiagonal, with the array $TAUP$, represent the orthogonal matrix $P$ as a product of elementary reflectors.

if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix $B$; the elements below the first subdiagonal, with the array $TAUQ$, represent the orthogonal matrix $Q$ as a product of elementary reflectors, and the elements above the diagonal, with the array $TAUP$, represent the orthogonal matrix $P$ as a product of elementary reflectors.

The user has to provide working space which is pointed by input parameter $Work$.

The input parameter $Lwork$ is size of the working space, and it is returned by $gebrd_bufferSize()$.

If output parameter $devInfo = -i$ (less than zero), the $i$-th parameter is wrong (not counting handle).

Remark: $gebrd$ only supports $m \geq n$.

2.4.3.2. cusolverDn<t>orgbr()

These helper functions calculate the size of work buffers needed.

```c
cusolverStatus_t
cusolverDnSorgbr_bufferSize(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    const float *A,
    int lda,
    const float *tau,
    int *lwork);

cusolverStatus_t
cusolverDnDorgbr_bufferSize(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    const double *A,
    int lda,
    const double *tau,
    int *lwork);

cusolverStatus_t
cusolverDnCungbr_bufferSize(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    const cuComplex *A,
    int lda,
    const cuComplex *tau,
    int *lwork);

cusolverStatus_t
cusolverDnZungbr_bufferSize(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    const cuDoubleComplex *A,
    int lda,
    const cuDoubleComplex *tau,
    int *lwork);
```
The S and D data types are real valued single and double precision, respectively.

cusolverStatus_t
cusolverDnSorgBr(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    float *A,
    int lda,
    const float *tau,
    float *work,
    int lwork,
    int *devInfo);

cusolverStatus_t
cusolverDnDorgBr(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    double *A,
    int lda,
    const double *tau,
    double *work,
    int lwork,
    int *devInfo);
The C and Z data types are complex valued single and double precision, respectively.

```c
 cusolverStatus_t
cusolverDnCungbr(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    cuComplex *A,
    int lda,
    const cuComplex *tau,
    cuComplex *work,
    int lwork,
    int *devInfo);

cusolverStatus_t
cusolverDnZungbr(
    cusolverDnHandle_t handle,
    cublasSideMode_t side,
    int m,
    int n,
    int k,
    cuDoubleComplex *A,
    int lda,
    const cuDoubleComplex *tau,
    cuDoubleComplex *work,
    int lwork,
    int *devInfo);
```

This function generates one of the unitary matrices $Q$ or $P^\text{H}$ determined by `gebrd` when reducing a matrix $A$ to bidiagonal form: $Q^H A P = B$.

$Q$ and $P^\text{H}$ are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

The user has to provide working space which is pointed by input parameter `work`.

The input parameter `lwork` is size of the working space, and it is returned by `orgbr_bufferSize()`.

If output parameter `devInfo = -i` (less than zero), the $i$-th parameter is wrong (not counting handle).

    int *devInfo);
This function reduces a general symmetric (Hermitian) \( n \times n \) matrix \( A \) to real symmetric tridiagonal form \( T \) by an orthogonal transformation: \( Q^H A Q = T \).

As an output, \( A \) contains \( T \) and householder reflection vectors. If \( \text{uplo} = \text{CUBLAS_FILL_MODE_UPPER} \), the diagonal and first superdiagonal of \( A \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements above the first superdiagonal, with the array \( \tau \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors; If \( \text{uplo} = \text{CUBLAS_FILL_MODE_LOWER} \), the diagonal and first subdiagonal of \( A \) are overwritten by the corresponding elements of the tridiagonal matrix \( T \), and the elements below the first subdiagonal, with the array \( \tau \), represent the orthogonal matrix \( Q \) as a product of elementary reflectors.

The user has to provide working space which is pointed by input parameter \( \text{work} \). The input parameter \( \text{lwork} \) is size of the working space, and it is returned by \( \text{sytrd_bufferSize()} \).

If output parameter \( \text{devInfo} = -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle).

    int lda,
    cuDoubleComplex *tau,
    cuDoubleComplex *C,
    int ldc,
    cuDoubleComplex *work,
    int lwork,
    int *devInfo);
```

This function overwrites $m \times n$ matrix $C$ by

$$
C = \begin{cases} 
\text{op}(Q)^*C & \text{if } \text{side} == \text{CUBLAS\_SIDE\_LEFT} \\
C^{\text{op}(Q)} & \text{if } \text{side} == \text{CUBLAS\_SIDE\_RIGHT} 
\end{cases}
$$

where $Q$ is a unitary matrix formed by a sequence of elementary reflection vectors from `sytrd`.

The operation on $Q$ is defined by

$$
\text{op}(Q) = \begin{cases} 
Q & \text{if } \text{transa} == \text{CUBLAS\_OP\_N} \\
Q^T & \text{if } \text{transa} == \text{CUBLAS\_OP\_T} \\
Q^H & \text{if } \text{transa} == \text{CUBLAS\_OP\_C} 
\end{cases}
$$

The user has to provide working space which is pointed by input parameter `work`. The input parameter `lwork` is size of the working space, and it is returned by `ormtr_bufferSize()`.

If output parameter `devInfo = -i` (less than zero), the $i$-th parameter is wrong (not counting handle).

  int lwork,
  int *devInfo);

This function generates a unitary matrix $Q$ which is defined as the product of n-1 elementary reflectors of order n, as returned by $\text{sytrd}$:

The user has to provide working space which is pointed by input parameter $\text{work}$. The input parameter $\text{lwork}$ is size of the working space, and it is returned by $\text{orgtr_bufferSize()}$. 
If output parameter `devInfo = -i` (less than zero), the `i-th` parameter is wrong (not counting handle).

int lwork,  
double *rwork,  
int *devInfo);
```

This function computes the singular value decomposition (SVD) of a \( m \times n \) matrix \( A \) and corresponding the left and/or right singular vectors. The SVD is written

\[
A = U \Sigma V^H
\]

where \( \Sigma \) is an \( m \times n \) matrix which is zero except for its \( \min(m,n) \) diagonal elements, \( U \) is an \( m \times m \) unitary matrix, and \( V \) is an \( n \times n \) unitary matrix. The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. The first \( \min(m,n) \) columns of \( U \) and \( V \) are the left and right singular vectors of \( A \).

The user has to provide working space which is pointed by input parameter `work`. The input parameter `lwork` is size of the working space, and it is returned by `gesvd_bufferSize()`.

If output parameter `devInfo = -i` (less than zero), the `i`-th parameter is wrong (not counting handle). if `bdsqr` did not converge, `devInfo` specifies how many superdiagonals of an intermediate bidiagonal form did not converge to zero.
The `rwork` is real array of dimension (min(m,n)-1). If `devInfo>0` and `rwork` is not nil, `rwork` contains the unconverged superdiagonal elements of an upper bidiagonal matrix. This is slightly different from LAPACK which puts unconverged superdiagonal elements in `work` if type is `real`; in `rwork` if type is `complex`. `rwork` can be a NULL pointer if the user does not want the information from superdiagonal.

Appendix G.1 provides a simple example of `gesvd`.

Remark 1: `gesvd` only supports `m>=n`.

Remark 2: the routine returns $V^H$, not $V$.

2.4.3.7. cusolverDnGesvd()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
 cusolverStatus_t cusolverDnGesvd_bufferSize(
    cusolverDnHandle_t handle,
    cusolverDnParams_t params,
    signed char jobu,
    signed char jobvt,
    int64_t m,
    int64_t n,
    cudaDataType dataTypeA,
    const void *A,
    int64_t lda,
    cudaDataType dataTypeS,
    const void *S,
    cudaDataType dataTypeU,
    const void *U,
    int64_t ldu,
    cudaDataType dataTypeVT,
    const void *VT,
    int64_t ldvt,
    cudaDataType computeType,
    size_t *workspaceInBytes);
```

The routine below

```c
 cusolverStatus_t CUSOLVERAPI cusolverDnGesvd(
    cusolverDnHandle_t handle,
    cusolverDnParams_t params,
    signed char jobu,
    signed char jobvt,
    int64_t m,
    int64_t n,
    cudaDataType dataTypeA,
    void *A,
    int64_t lda,
    cudaDataType dataTypeS,
    void *S,
    cudaDataType dataTypeU,
    void *U,
    int64_t ldu,
    cudaDataType dataTypeVT,
    void *VT,
    int64_t ldvt,
    cudaDataType computeType,
    void *pBuffer,
    size_t workspaceInBytes,
    int *info);
```

This function computes the singular value decomposition (SVD) of a \( m \times n \) matrix \( A \) and corresponding the left and/or right singular vectors. The SVD is written

\[
A = U \Sigma V^T
\]

where \( \Sigma \) is an \( m \times n \) matrix which is zero except for its \( \min(m,n) \) diagonal elements, \( U \) is an \( m \times m \) unitary matrix, and \( V \) is an \( n \times n \) unitary matrix. The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. The first \( \min(m,n) \) columns of \( U \) and \( V \) are the left and right singular vectors of \( A \).
The user has to provide working space which is pointed by input parameter `pBuffer`. The input parameter `workspaceInBytes` is size in bytes of the working space, and it is returned by `cusolverDnGesvd_bufferSize()`.

If output parameter `info = -i` (less than zero), the i-th parameter is wrong (not counting handle). If `bdsqr` did not converge, `info` specifies how many superdiagonals of an intermediate bidiagonal form did not converge to zero.

Currently, `cusolverDnGesvd` supports only the default algorithm.

Table of algorithms supported by `cusolverDnGesvd`

| CUSOLVER_ALG_0 or NULL | Default algorithm. |

Appendix G.5 provides a simple example of `cusolverDnGesvd`.

Remark 1: `gesvd` only supports `m>=n`.

Remark 2: the routine returns $V^H$, not $V$.

List of input arguments for `cusolverDnGesvd_bufferSize` and `cusolverDnGesvd`:

    int ldv,
    cuDoubleComplex *work,
    int lwork,
    int *info,
    gesvdjInfo_t params);

This function computes the singular value decomposition (SVD) of a \( m \times n \) matrix \( A \) and corresponding the left and/or right singular vectors. The SVD is written

\[
A = U \Sigma V^H
\]

where \( \Sigma \) is an \( m \times n \) matrix which is zero except for its \( \min(m,n) \) diagonal elements, \( U \) is an \( m \times m \) unitary matrix, and \( V \) is an \( n \times n \) unitary matrix. The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. The first \( \min(m,n) \) columns of \( U \) and \( V \) are the left and right singular vectors of \( A \).

gesvdj has the same functionality as gesvd. The difference is that gesvd uses QR algorithm and gesvdj uses Jacobi method. The parallelism of Jacobi method gives GPU better performance on small and medium size matrices. Moreover the user can configure gesvdj to perform approximation up to certain accuracy.
gesvdj iteratively generates a sequence of unitary matrices to transform matrix $A$ to the following form

$$U^H A^* V = S + E$$

where $S$ is diagonal and diagonal of $E$ is zero.

During the iterations, the Frobenius norm of $E$ decreases monotonically. As $E$ goes down to zero, $S$ is the set of singular values. In practice, Jacobi method stops if

$$||E||_F \leq \text{eps} * ||A||_F$$

where eps is given tolerance.

gesvdj has two parameters to control the accuracy. First parameter is tolerance (eps). The default value is machine accuracy but The user can use function $\text{cusolverDnXgesvdjSetTolerance}$ to set a priori tolerance. The second parameter is maximum number of sweeps which controls number of iterations of Jacobi method. The default value is 100 but the user can use function $\text{cusolverDnXgesvdjSetMaxSweeps}$ to set a proper bound. The experiments show 15 sweeps are good enough to converge to machine accuracy. gesvdj stops either tolerance is met or maximum number of sweeps is met.

Jacobi method has quadratic convergence, so the accuracy is not proportional to number of sweeps. To guarantee certain accuracy, the user should configure tolerance only.

The user has to provide working space which is pointed by input parameter work. The input parameter $lwork$ is the size of the working space, and it is returned by $\text{gesvdj_bufferSize}()$.

If output parameter $info = -i$ (less than zero), the $i$-th parameter is wrong (not counting handle). If $info = \min(m,n)+1$, gesvdj does not converge under given tolerance and maximum sweeps.

If the user sets an improper tolerance, gesvdj may not converge. For example, tolerance should not be smaller than machine accuracy.

Appendix G.2 provides a simple example of gesvdj.

Remark 1: gesvdj supports any combination of $m$ and $n$.

Remark 2: the routine returns $V$, not $V^H$. This is different from gesvd.

</tbody>
</table>

This function computes singular values and singular vectors of a sequence of general $m \times n$ matrices

$$A_j = U_j \Sigma_j^* V_j^H$$

where $\Sigma_j$ is a real $m \times n$ diagonal matrix which is zero except for its $\min(m,n)$ diagonal elements. $U_j$ (left singular vectors) is a $m \times m$ unitary matrix and $V_j$ (right singular vectors) is a $n \times n$ unitary matrix. The diagonal elements of $\Sigma_j$ are the singular values of $A_j$ in either descending order or non-sorting order.

gesvdjBatched performs gesvdj on each matrix. It requires that all matrices are of the same size $m, n$ no greater than 32 and are packed in contiguous way,

$$A = (A_0 \ A_1 \ \ldots)$$
Each matrix is column-major with leading dimension \( \text{lda} \), so the formula for random access is \( A_k(i,j) = A[i + \text{lda}^*j + \text{lda}^*n^*k] \).

The parameter \( S \) also contains singular values of each matrix in contiguous way,

\[
S = (S0 \quad S1 \quad \cdots)
\]

The formula for random access of \( S \) is \( S_k(j) = S[j + \min(m, n)^*k] \).

Except for tolerance and maximum sweeps, \texttt{gesvdjBatched} can either sort the singular values in descending order (default) or chose as-is (without sorting) by the function \texttt{cusolverDnXgesvdjSetSortEig}. If the user packs several tiny matrices into diagonal blocks of one matrix, non-sorting option can separate singular values of those tiny matrices.

\texttt{gesvdjBatched} cannot report residual and executed sweeps by function \texttt{cusolverDnXgesvdjGetResidual} and \texttt{cusolverDnXgesvdjGetSweeps}. Any call of the above two returns \texttt{CUSOLVER\_STATUS\_NOT\_SUPPORTED}. The user needs to compute residual explicitly.

The user has to provide working space pointed by input parameter \texttt{work}. The input parameter \texttt{lwork} is the size of the working space, and it is returned by \texttt{gesvdjBatched\_bufferSize}().

The output parameter \texttt{info} is an integer array of size \( \text{batchSize} \). If the function returns \texttt{CUSOLVER\_STATUS\_INVALID\_VALUE}, the first element \texttt{info[0]} = \( -i \) (less than zero) indicates \( i \)-th parameter is wrong (not counting handle). Otherwise, if \texttt{info[i]} = \( \min(m, n) + 1 \), \texttt{gesvdjBatched} does not converge on \( i \)-th matrix under given tolerance and maximum sweeps.

Appendix G.3 provides a simple example of \texttt{gesvdjBatched}.

```

This function *gesvda* (a stands for approximate) approximates the singular value decomposition of a tall skinny \( m \times n \) matrix \( A \) and corresponding the left and right singular vectors. The economy form of SVD is written by

\[
A = U \Sigma V^H
\]
where \( \Sigma \) is an \( n \times n \) matrix. \( U \) is an \( m \times n \) unitary matrix, and \( V \) is an \( n \times n \) unitary matrix. The diagonal elements of \( \Sigma \) are the singular values of \( A \); they are real and non-negative, and are returned in descending order. \( U \) and \( V \) are the left and right singular vectors of \( A \).

\texttt{gesvda} computes eigenvalues of \( A**T * A \) to approximate singular values and singular vectors. It generates matrices \( U \) and \( V \) and transforms the matrix \( A \) to the following form

\[
U^H \cdot A \cdot V = S + E
\]

where \( S \) is diagonal and \( E \) depends on rounding errors. To certain conditions, \( U, V \) and \( S \) approximate singular values and singular vectors up to machine zero of single precision. In general, \( V \) is unitary, \( S \) is more accurate than \( U \). If singular value is far from zero, then left singular vector \( U \) is accurate. In other words, the accuracy of singular values and left singular vectors depend on the distance between singular value and zero.

The input parameter \texttt{rank} decides the number of singular values and singular vectors are computed in parameter \( S, U \) and \( V \).

The output parameter \texttt{h_RnrmF} computes Frobenius norm of residual.

\[
A - U \cdot S \cdot V^H
\]

if the parameter \texttt{rank} is equal \( n \). Otherwise, \texttt{h_RnrmF} reports

\[
||U \cdot S \cdot V^H|| - ||S||
\]

in Frobenius norm sense. That is, how far \( U \) is from unitary.

\texttt{gesvdaStridedBatched} performs \texttt{gesvda} on each matrix. It requires that all matrices are of the same size \( m, n \) and are packed in contiguous way.

\[
A = (A0 \ A1 \ -)\text{.}
\]

Each matrix is column-major with leading dimension \( \text{lda} \), so the formula for random access is \( A_k(i,j) = A[i + \text{lda}*j + \text{strideA}*k] \). Similarly, the formula for random access of \( S \) is \( S_k(j) = S[j + \text{strideS}*k] \), the formula for random access of \( U \) is \( U_k(i,j) = U[i + \text{ldu}*j + \text{strideU}*k] \) and the formula for random access of \( V \) is \( V_k(i,j) = V[i + \text{ldv}*j + \text{strideV}*k] \).

The user has to provide working space which is pointed by input parameter \texttt{work}.

The input parameter \texttt{lwork} is the size of the working space, and it is returned by \texttt{gesvdaStridedBatched_bufferSize()}. The output parameter \texttt{info} is an integer array of size \texttt{batchSize}. If the function returns \texttt{CUSOLVER_STATUS_INVALID_VALUE}, the first element \texttt{info[0]} = -i (less than zero) indicates \( i \)-th parameter is wrong (not counting handle). Otherwise, if \texttt{info[i]} = \texttt{min(m,n)+1}, \texttt{gesvdaStridedBatched} does not converge on \( i \)-th matrix under given tolerance.

Appendix G.4 provides a simple example of \texttt{gesvda}.

Remark 1: the routine returns \( V \), not \( V^H \). This is different from \texttt{gesvd}.
Remark 2: if the user is confident on the accuracy of singular values and singular vectors, for example, certain conditions hold (required singular value is far from zero), then the performance can be improved by passing null pointer to h_RnrmF, i.e. no computation of residual norm.

cusolverDnDsyevd_bufferSize(
    cusolverDnHandle_t handle,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n,
    const double *A,
    int lda,
    const double *W,
    int *lwork);

cusolverStatus_t
cusolverDnCheevd_bufferSize(
    cusolverDnHandle_t handle,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n,
    const cuComplex *A,
    int lda,
    const float *W,
    int *lwork);

cusolverStatus_t
cusolverDnZheevd_bufferSize(
    cusolverDnHandle_t handle,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n,
    const cuDoubleComplex *A,
    int lda,
    const double *W,
    int *lwork);
```
The S and D data types are real valued single and double precision, respectively.

```c
int n, float *A, int lda, float *W, float *work, int lwork, int *devInfo);
```

cusolverStatus_t
cusolverDnDsyevd(
    cusolverDnHandle_t handle,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n, double *A, int lda, double *W, double *work, int lwork, int *devInfo);
```

The C and Z data types are complex valued single and double precision, respectively.

```c
int n, cuComplex *A, int lda, float *W, cuComplex *work, int lwork, int *devInfo);
```

cusolverStatus_t
cusolverDnCheevd(
    cusolverDnHandle_t handle,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n, cuComplex *A, int lda, float *W, cuComplex *work, int lwork, int *devInfo);
```

cusolverStatus_t
cusolverDnZheevd(
    cusolverDnHandle_t handle,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n, cuDoubleComplex *A, int lda, double *W, cuDoubleComplex *work, int lwork, int *devInfo);
```

This function computes eigenvalues and eigenvectors of a symmetric (Hermitian) \( n \times n \) matrix \( A \). The standard symmetric eigenvalue problem is

\[
A^* V = V^* A
\]
where $\Lambda$ is a real $n \times n$ diagonal matrix. $V$ is an $n \times n$ unitary matrix. The diagonal elements of $\Lambda$ are the eigenvalues of $A$ in ascending order.

The user has to provide working space which is pointed by input parameter `work`. The input parameter `lwork` is size of the working space, and it is returned by `syevd_bufferSize()`.

If output parameter `devInfo = -i` (less than zero), the $i$-th parameter is wrong (not counting handle). If `devInfo = i` (greater than zero), $i$ off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

if `jobz = CUSOLVER_EIG_MODE_VECTOR`, $A$ contains the orthonormal eigenvectors of the matrix $A$. The eigenvectors are computed by a divide and conquer algorithm.

Appendix F.1 provides a simple example of `syevd`.

### 2.4.3.12. cusolverDnSyevd()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
cusolverStatus_t
cusolverDnSyevd_bufferSize(  
cusolverDnHandle_t handle,  
cusolverParams_t params,  
cusolverEigMode_t jobz,  
cublasFillMode_t uplo,  
int n,  
cudaDataType dataTypeA,  
const void *A,  
int64_t lda,  
cudaDataType dataTypeW,  
const void *W,  
cudaDataType computeType,  
size_t *workspaceInBytes);
```
The routine bellow

```c
 cusolverStatus_t
cusolverDnSyevd(
    cusolverDnHandle_t handle,
    cusolverParams_t params,
    cusolverEigMode_t jobz,
    cublasFillMode_t uplo,
    int n,
    cudaDataType dataTypeA,
    const void *A,
    int64_t lda,
    cudaDataType dataTypeW,
    const void *W,
    cudaDataType computeType,
    void *pBuffer,
    size_t workspaceInBytes,
    int *info);
```

computes eigenvalues and eigenvectors of a symmetric (Hermitian) $n \times n$ matrix $A$ using the generic API interface. The standard symmetric eigenvalue problem is

$$A^* V = V^* A$$

where $A$ is a real $n \times n$ diagonal matrix, $V$ is an $n \times n$ unitary matrix. The diagonal elements of $A$ are the eigenvalues of $A$ in ascending order.

The user has to provide working space which is pointed by input parameter $pBuffer$. The input parameter $workspaceInBytes$ is size in bytes of the working space, and it is returned by $cusolverDnSyevd_bufferSize()$.

If output parameter $info = -i$ (less than zero), the $i$-th parameter is wrong (not counting handle). If $info = i$ (greater than zero), $i$ off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

if $jobz = CUSOLVER_EIG_MODEVECTOR$, $A$ contains the orthonormal eigenvectors of the matrix $A$. The eigenvectors are computed by a divide and conquer algorithm.

Currently, $cusolverDnSyevd$ supports only the default algorithm.

    int iu,
    int *h_meig,
    double *W,
    cuDoubleComplex *work,
    int lwork,
    int *devInfo);

This function computes all or selection of the eigenvalues and optionally eigenvectors of a symmetric (Hermitian) $n \times n$ matrix $A$. The standard symmetric eigenvalue problem is

$$A^*V = V^*A$$

where $A$ is a real $n \times h \_meig$ diagonal matrix. $V$ is an $n \times h \_meig$ unitary matrix. $h \_meig$ is the number of eigenvalues/eigenvectors computed by the routine, $h \_meig$ is equal to $n$ when the whole spectrum (e.g., range = CUSOLVER_EIG_RANGE_ALL) is requested. The diagonal elements of $A$ are the eigenvalues of $A$ in ascending order.

The user has to provide working space which is pointed by input parameter work. The input parameter lwork is size of the working space, and it is returned by syevdx\_bufferSize().

If output parameter devInfo = $-i$ (less than zero), the $i\text{-th}$ parameter is wrong (not counting handle). If devInfo $= i$ (greater than zero), $i$ off-diagonal elements of an intermediate tridiagonal form did not converge to zero.
if `jobz = CUSOLVER_EIG_MODE_VECTOR`, \( A \) contains the orthonormal eigenvectors of the matrix \( A \). The eigenvectors are computed by a divide and conquer algorithm.

Appendix F.1 provides a simple example of `syevdx`.

</table>
interval to be searched for eigenvalues. \( vl > vu \). Not referenced if `range` = `CUSOLVER_EIG_RANGE_ALL` or `range` = `CUSOLVER_EIG_RANGE_I`. Note that, if eigenvalues are very close to each other, it is well known that two different eigenvalues routines might find slightly different number of eigenvalues inside the same interval. This is due to the fact that different eigenvalue algorithms, or even same algorithm but different run might find eigenvalues within some rounding error close to the machine precision. Thus, if the user want to be sure not to miss any eigenvalue within the interval bound, we suggest that, the user subtract/add epsilon (machine precision) to the interval bound such as \( (vl=vl-\text{eps}, \ vu=vu+\text{eps}) \). This suggestion is valid for any selective routine from cuSolver or LAPACK.

| il, iu  | host  | input  | integer. If `range` = `CUSOLVER_EIG_RANGE_I`, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. \( 1 \leq il \leq iu \leq n \), if \( n > 0 \); \( il = 1 \) and \( iu = 0 \) if \( n = 0 \). Not referenced if `range` = `CUSOLVER_EIG_RANGE_ALL` or `range` = `CUSOLVER_EIG_RANGE_V`. |
|--------|-------|--------|

| h_meig  | host  | output | integer. The total number of eigenvalues found. \( 0 \leq h\_\text{meig} \leq n \). If `range` = `CUSOLVER_EIG_RANGE_ALL`, \( h\_\text{meig} = n \), and if `range` = `CUSOLVER_EIG_RANGE_I`, \( h\_\text{meig} = iu-il+1 \). |
|--------|-------|--------|

| W      | device | output | a real array of dimension \( n \). The eigenvalue values of \( A \), in ascending order ie, sorted so that \( W(i) \leq W(i+1) \). |

### CUSOLVER_STATUS_INVALID_VALUE
Invalid parameters were passed (n<0, or lda<max(1,n), or jobz is not CUSOLVER_EIG_MODE_NOVECTOR or CUSOLVER_EIG_MODE_VECTOR, or range is not CUSOLVER_EIG_RANGE_ALL or CUSOLVER_EIG_RANGE_V or CUSOLVER_EIG_RANGE_I, or uplo is not CUBLAS_FILL_MODE_LOWER or CUBLAS_FILL_MODE_UPPER).

### CUSOLVER_STATUS_ARCH_MISMATCH
The device only supports compute capability 2.0 and above.

### CUSOLVER_STATUS_INTERNAL_ERROR
An internal operation failed.

### 2.4.3.14. cusolverDnSyevdx()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
cusolverStatus_t
cusolverDnSyevdx_bufferSize(
cusolverDnHandle_t handle,
cusolverParams_t params,
cusolverEigMode_t jobz,
cusolverEigRange_t range,
cublasFillMode_t uplo,
int n,
cudaDataType dataTypeA,
const void *A,
int64_t lda,
void *vl,
void *vu,
int64_t *h_meig,
int64_t *h_meig,
cudaDataType dataTypeW,
const void *W,
cudaDataType computeType,
size_t *workspaceInBytes);
```
The routine below

```c
 cusolverStatus_t
cusolverDnSyevdx (  
cusolverDnHandle_t handle,  
cusolverParams_t params,  
cusolverEigMode_t jobz,  
cusolverEigRange_t range,  
cublasFillMode_t uplo,  
int n,  
cudaDataType dataTypeA,  
const void *A,  
int64_t lda,  
void *vl,  
void *vu,  
int64_t il,  
int64_t iu,  
int64_t *h_meig,  
cudaDataType dataTypeW,  
const void *W,  
cudaDataType computeType,  
void *pBuffer,  
size_t workspaceInBytes,  
int *info);
```

computes all or selection of the eigenvalues and optionally eigenvectors of a symmetric (Hermitian) \(n \times n\) matrix \(A\) using the generic API interface. The standard symmetric eigenvalue problem is

\[ A^* V = V \Lambda \]

where \(\Lambda\) is a real \(n \times h\_meig\) diagonal matrix, \(V\) is an \(n \times h\_meig\) unitary matrix. \(h\_meig\) is the number of eigenvalues/eigenvectors computed by the routine, \(h\_meig\) is equal to \(n\) when the whole spectrum (e.g., \(range = \text{CUSOLVER\_EIG\_RANGE\_ALL}\)) is requested. The diagonal elements of \(\Lambda\) are the eigenvalues of \(A\) in ascending order.

The user has to provide working space which is pointed by input parameter \(pBuffer\). The input parameter \(workspaceInBytes\) is size in bytes of the working space, and it is returned by \(\text{cusolverDnSyevdx\_BufferSize()}\).

If output parameter \(info = -i\) (less than zero), the \(i\)-th parameter is wrong (not counting handle). If \(info = i\) (greater than zero), \(i\) off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

if \(jobz = \text{CUSOLVER\_EIG\_MODE\_VECTOR}\), \(A\) contains the orthonormal eigenvectors of the matrix \(A\). The eigenvectors are computed by a divide and conquer algorithm.

Currently, \(\text{cusolverDnSyevdx}\) supports only the default algorithm.

**Table of algorithms supported by cusolverDnSyevdx**

| CUSOLVER\_ALG\_0 or NULL | Default algorithm. |

    int ldb,
    double *W,
    cuDoubleComplex *work,
    int lwork,
    int *devInfo);

This function computes eigenvalues and eigenvectors of a symmetric (Hermitian) \( n \times n \) matrix-pair \((A, B)\). The generalized symmetric-definite eigenvalue problem is

\[
eig(A, B) = \begin{cases} 
A^* V = B^* V^* A & \text{if } \text{itype} = \text{CUSOLVER_EIG_TYPE_1} \\
A^* B^* V = V^* A & \text{if } \text{itype} = \text{CUSOLVER_EIG_TYPE_2} \\
B^* A^* V = V^* A & \text{if } \text{itype} = \text{CUSOLVER_EIG_TYPE_3}
\end{cases}
\]

where the matrix \( B \) is positive definite. \( A \) is a real \( n \times n \) diagonal matrix. The diagonal elements of \( A \) are the eigenvalues of \((A, B)\) in ascending order. \( V \) is an \( n \times n \) orthogonal matrix. The eigenvectors are normalized as follows:

\[
\begin{cases} 
V^H B^* V = I & \text{if } \text{itype} = \text{CUSOLVER_EIG_TYPE_1}, \text{CUSOLVER_EIG_TYPE_2} \\
V^H \text{inv}(B)^* V = I & \text{if } \text{itype} = \text{CUSOLVER_EIG_TYPE_3}
\end{cases}
\]

The user has to provide working space which is pointed by input parameter \( \text{work} \). The input parameter \( \text{lwork} \) is size of the working space, and it is returned by \( \text{sygvd_bufferSize()} \).

If output parameter \( \text{devInfo} = -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle). If \( \text{devInfo} = i \) (\( i > 0 \) and \( i \leq n \)) and \( \text{jobz} = \text{CUSOLVER_EIG_MODE_NOVECTOR} \), \( i \)-off-diagonal elements of an intermediate tridiagonal form did not converge to zero. If \( \text{devInfo} = N + i \) (\( i > 0 \)), then the
leading minor of order $i$ of $B$ is not positive definite. The factorization of $B$ could not be completed and no eigenvalues or eigenvectors were computed.

If $jobz = \text{CUSOLVER\_EIG\_MODE\_VECTOR}$, $A$ contains the orthogonal eigenvectors of the matrix $A$. The eigenvectors are computed by divide and conquer algorithm.

Appendix F.2 provides a simple example of $\text{sgyvdp}$.

This function computes all or selection of the eigenvalues and optionally eigenvectors of a symmetric (Hermitian) $n \times n$ matrix-pair ($A, B$). The generalized symmetric-definite eigenvalue problem is

$$eig(A, B) = \begin{cases} A^* V = B^* V^* \Lambda & \text{if } itype = \text{CUSOLVER_EIG_TYPE_1} \\ A^* B^* V = V^* \Lambda & \text{if } itype = \text{CUSOLVER_EIG_TYPE_2} \\ B^* A^* V = V^* \Lambda & \text{if } itype = \text{CUSOLVER_EIG_TYPE_3} \end{cases}$$

where the matrix $B$ is positive definite. $\Lambda$ is a real $n \times h\_meig$ diagonal matrix. The diagonal elements of $\Lambda$ are the eigenvalues of $(A, B)$ in ascending order. $V$ is an $n \times h\_meig$ orthogonal matrix. $h\_meig$ is the number of eigenvalues/eigenvectors.
computed by the routine, \( h_{\text{meig}} \) is equal to \( n \) when the whole spectrum (e.g., range = CUSOLVER_EIG_RANGE_ALL) is requested. The eigenvectors are normalized as follows:

\[
\begin{align*}
V^H B V &= I & \text{if } itype = \text{CUSOLVER_EIG_TYPE}_1, \text{CUSOLVER_EIG_TYPE}_2 \\
V^H \text{inv}(B) V &= I & \text{if } itype = \text{CUSOLVER_EIG_TYPE}_3
\end{align*}
\]

The user has to provide working space which is pointed by input parameter \( \text{work} \). The input parameter \( \text{lwork} \) is size of the working space, and it is returned by \text{sygvdx_bufferSize()}.

If output parameter \( \text{devInfo} = -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle). If \( \text{devInfo} = i \) \((i \geq 0 \text{ and } i < n)\) and \( \text{jobz} = \text{CUSOLVER_EIG_MODE_NOVECTOR} \), \( i \) off-diagonal elements of an intermediate tridiagonal form did not converge to zero. If \( \text{devInfo} = n + i \) \((i > 0)\), then the leading minor of order \( i \) of \( B \) is not positive definite. The factorization of \( B \) could not be completed and no eigenvalues or eigenvectors were computed.

If \( \text{jobz} = \text{CUSOLVER_EIG_MODE_VECTOR} \), \( A \) contains the orthogonal eigenvectors of the matrix \( A \). The eigenvectors are computed by divide and conquer algorithm.

Appendix F.2 provides a simple example of \text{sygvdx}.

syevjInfo_t params);

This function computes eigenvalues and eigenvectors of a symmetric (Hermitian) \( n \times n \) matrix \( \mathbf{A} \). The standard symmetric eigenvalue problem is
\[ A^*Q = Q^*A \]

where \( A \) is a real \( n \times n \) diagonal matrix, \( Q \) is an \( n \times n \) unitary matrix. The diagonal elements of \( A \) are the eigenvalues of \( A \) in ascending order.

**syevj** has the same functionality as **syevd**. The difference is that **syevd** uses QR algorithm and **syevj** uses Jacobi method. The parallelism of Jacobi method gives GPU better performance on small and medium size matrices. Moreover the user can configure **syevj** to perform approximation up to certain accuracy.

How does it work?

**syevj** iteratively generates a sequence of unitary matrices to transform matrix \( A \) to the following form

\[ V^H A V = W + E \]

where \( W \) is diagonal and \( E \) is symmetric without diagonal.

During the iterations, the Frobenius norm of \( E \) decreases monotonically. As \( E \) goes down to zero, \( W \) is the set of eigenvalues. In practice, Jacobi method stops if

\[ ||E||_F \leq \text{eps} \times ||A||_F \]

where **eps** is given tolerance.

**syevj** has two parameters to control the accuracy. First parameter is tolerance (**eps**). The default value is machine accuracy but The user can use function **cusolverDnXsyevjSetTolerance** to set a priori tolerance. The second parameter is maximum number of sweeps which controls number of iterations of Jacobi method. The default value is 100 but the user can use function **cusolverDnXsyevjSetMaxSweeps** to set a proper bound. The experiments show 15 sweeps are good enough to converge to machine accuracy. **syevj** stops either tolerance is met or maximum number of sweeps is met.

Jacobi method has quadratic convergence, so the accuracy is not proportional to number of sweeps. To guarantee certain accuracy, the user should configure tolerance only.

After **syevj**, the user can query residual by function **cusolverDnXsyevjGetResidual** and number of executed sweeps by function **cusolverDnXsyevjGetSweeps**. However the user needs to be aware that residual is the Frobenius norm of \( E \), not accuracy of individual eigenvalue, i.e.

\[ \text{residual} = ||E||_F = ||A - W||_F \]

The same as **syevd**, the user has to provide working space pointed by input parameter **work**. The input parameter **lwork** is the size of the working space, and it is returned by **syevj_bufferSize()**.

If output parameter **info** = -i (less than zero), the **i-th** parameter is wrong (not counting handle). If **info** = n+1, **syevj** does not converge under given tolerance and maximum sweeps.
Using the CUSOLVER API

If the user sets an improper tolerance, \texttt{syevj} may not converge. For example, tolerance should not be smaller than machine accuracy.

if \texttt{jobz} = CUSOLVER\_EIG\_MODE\_VECTOR, \texttt{A} contains the orthonormal eigenvectors \texttt{V}.

Appendix F.3 provides a simple example of \texttt{syevj}.

```

This function computes eigenvalues and eigenvectors of a symmetric (Hermitian) $n \times n$ matrix-pair $(A, B)$. The generalized symmetric-definite eigenvalue problem is

$$\text{eig}(A, B) = \begin{cases} 
A^* V = B^* V \Lambda & \text{if } \text{itype} = \text{CUSOLVER\_EIG\_TYPE\_1} \\
A^* B^* V = V \Lambda & \text{if } \text{itype} = \text{CUSOLVER\_EIG\_TYPE\_2} \\
B^* A^* V = V \Lambda & \text{if } \text{itype} = \text{CUSOLVER\_EIG\_TYPE\_3} 
\end{cases}$$

where the matrix $B$ is positive definite. $\Lambda$ is a real $n \times n$ diagonal matrix. The diagonal elements of $\Lambda$ are the eigenvalues of $(A, B)$ in ascending order. $V$ is an $n \times n$ orthogonal matrix. The eigenvectors are normalized as follows:

$$\begin{align*} 
V^H B^* V &= I & \text{if } \text{itype} = \text{CUSOLVER\_EIG\_TYPE\_1}, \text{CUSOLVER\_EIG\_TYPE\_2} \\
V^H \text{inv}(B)^* V &= I & \text{if } \text{itype} = \text{CUSOLVER\_EIG\_TYPE\_3}
\end{align*}$$

This function has the same functionality as $\text{sygvd}$ except that $\text{syevd}$ in $\text{sygvd}$ is replaced by $\text{syevj}$ in $\text{sygvj}$. Therefore, $\text{sygvj}$ inherits properties of $\text{syevj}$, the user can use $\text{cusolverDnXsyevjSetTolerance}$ and $\text{cusolverDnXsyevjSetMaxSweeps}$ to configure tolerance and maximum sweeps.
However the meaning of residual is different from \texttt{syevj}. \texttt{sygvj} first computes Cholesky factorization of matrix $B$,

$$B = L \cdot L^H$$

transform the problem to standard eigenvalue problem, then calls \texttt{syevj}.

For example, the standard eigenvalue problem of type I is

$$M^* Q = Q^* \Lambda$$

where matrix $M$ is symmetric

$$M = L^{-1} A L^{-H}$$

The residual is the result of \texttt{syevj} on matrix $M$, not $A$.

The user has to provide working space which is pointed by input parameter \texttt{work}. The input parameter \texttt{lwork} is the size of the working space, and it is returned by \texttt{sygvj_bufferSize()}. If output parameter \texttt{info} = $-i$ (less than zero), the $i$-th parameter is wrong (not counting handle). If \texttt{info} = $i$ ($i > 0$ and $i <= n$), $B$ is not positive definite, the factorization of $B$ could not be completed and no eigenvalues or eigenvectors were computed. If \texttt{info} = $n+1$, \texttt{syevj} does not converge under given tolerance and maximum sweeps. In this case, the eigenvalues and eigenvectors are still computed because non-convergence comes from improper tolerance of maximum sweeps.

if \texttt{jobz} = \texttt{CUSOLVER_EIG_MODE_VECTOR}, $A$ contains the orthogonal eigenvectors $V$.

Appendix F.4 provides a simple example of \texttt{sygvj}.

    double *W,
    double *work,
    int lwork,
    int *info,
    syevjInfo_t params,
    int batchSize
);
```
The C and Z data types are complex valued single and double precision, respectively.

cusolverStatus_t
cusolverDnCheevjBatched(
   cusolverDnHandle_t handle,
   cusolverEigMode_t jobz,
   cublasFillMode_t uplo,
   int n,
   cuComplex *A,
   int lda,
   float *W,
   cuComplex *work,
   int lwork,
   int *info,
   syevjInfo_t params,
   int batchSize
);

This function computes eigenvalues and eigenvectors of a sequence of symmetric (Hermitian) $n \times n$ matrices

$$A_j Q_j = Q_j A_j$$

where $A_j$ is a real $n \times n$ diagonal matrix, $Q_j$ is an $n \times n$ unitary matrix. The diagonal elements of $A_j$ are the eigenvalues of $A_j$ in either ascending order or non-sorting order.

syevjBatched performs syevj on each matrix. It requires that all matrices are of the same size $n$ and are packed in contiguous way,

$$A = \begin{pmatrix} A_0 & A_1 & \cdots \\ \end{pmatrix}$$

Each matrix is column-major with leading dimension $lda$, so the formula for random access is $A_k(i,j) = A[i + lda*j + lda*n*k]$.

The parameter $w$ also contains eigenvalues of each matrix in contiguous way,

$$W = \begin{pmatrix} W_0 & W_1 & \cdots \\ \end{pmatrix}$$

The formula for random access of $w$ is $W_k(j) = W[j + n*k]$.
Except for tolerance and maximum sweeps, `syevjBatched` can either sort the eigenvalues in ascending order (default) or chose as-is (without sorting) by the function `cusolverDnXsyevjSetSortEig`. If the user packs several tiny matrices into diagonal blocks of one matrix, non-sorting option can separate spectrum of those tiny matrices.

`syevjBatched` cannot report residual and executed sweeps by function `cusolverDnXsyevjGetResidual` and `cusolverDnXsyevjGetSweeps`. Any call of the above two returns `CUSOLVER_STATUS_NOT_SUPPORTED`. The user needs to compute residual explicitly.

The user has to provide working space pointed by input parameter `work`. The input parameter `lwork` is the size of the working space, and it is returned by `syevjBatched_bufferSize()`.

The output parameter `info` is an integer array of size `batchSize`. If the function returns `CUSOLVER_STATUS_INVALID_VALUE`, the first element `info[0] = -i` (less than zero) indicates i-th parameter is wrong (not counting handle). Otherwise, if `info[i] = n+1`, `syevjBatched` does not converge on i-th matrix under given tolerance and maximum sweeps.

if `jobz = CUSOLVER_EIG_MODE_VECTOR`, $A_j$ contains the orthonormal eigenvectors $V_j$.

Appendix F.5 provides a simple example of `syevjBatched`.

2.5.1.1. cusolverSpCreate()

cusolverStatus_t

cusolverSpCreate(cusolverSpHandle_t *handle)

This function initializes the cuSolverSP library and creates a handle on the cuSolver context. It must be called before any other cuSolverSP API function is invoked. It allocates hardware resources necessary for accessing the GPU.

Output

| handle | the pointer to the handle to the cuSolverSP context. |

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the initialization succeeded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the CUDA Runtime initialization failed.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_ALLOC_FAILED</td>
<td>the resources could not be allocated.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_ARCH_MISMATCH</td>
<td>the device only supports compute capability 2.0 and above.</td>
</tr>
</tbody>
</table>

2.5.1.2. cusolverSpDestroy()

cusolverStatus_t

cusolverSpDestroy(cusolverSpHandle_t handle)

This function releases CPU-side resources used by the cuSolverSP library.

Input

| handle | the handle to the cuSolverSP context. |

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the shutdown succeeded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
</tbody>
</table>

2.5.1.3. cusolverSpSetStream()

cusolverStatus_t

cusolverSpSetStream(cusolverSpHandle_t handle, cudaStream_t streamId)

This function sets the stream to be used by the cuSolverSP library to execute its routines.

Input

| handle | the handle to the cuSolverSP context. |
| streamId | the stream to be used by the library. |

Status Returned

| CUSOLVER_STATUS_SUCCESS | the stream was set successfully. |
CUSOLVER_STATUS_NOT_INITIALIZED  the library was not initialized.

2.5.1.4. cusolverSpXcsrissym()

cusolverStatus_t
cusolverSpXcsrissymHost(cusolverSpHandle_t handle,
  int m,
  int nnzA,
  const cusparseMatDescr_t descrA,
  const int *csrRowPtrA,
  const int *csrEndPtrA,
  const int *csrColIndA,
  int *issym);

This function checks if \( A \) has symmetric pattern or not. The output parameter \( \text{issym} \) reports 1 if \( A \) is symmetric; otherwise, it reports 0.

The matrix \( A \) is an \( m \times m \) sparse matrix that is defined in CSR storage format by the four arrays \( \text{csrValA} \), \( \text{csrRowPtrA} \), \( \text{csrEndPtrA} \) and \( \text{csrColIndA} \).

The supported matrix type is \texttt{CUSPARSE\_MATRIX\_TYPE\_GENERAL}.

The \texttt{csrlsvlu} and \texttt{csrlsvqr} do not accept non-general matrix. the user has to extend the matrix into its missing upper/lower part, otherwise the result is not expected. The user can use \texttt{csrissym} to check if the matrix has symmetric pattern or not.

Remark 1: only CPU path is provided.

Remark 2: the user has to check returned status to get valid information. The function converts \( A \) to CSC format and compare CSR and CSC format. If the CSC failed because of insufficient resources, \( \text{issym} \) is undefined, and this state can only be detected by the return status code.

Input

<table>

2.5.2. High Level Function Reference

This section describes high level API of cuSolverSP, including linear solver, least-square solver and eigenvalue solver. The high-level API is designed for ease-of-use, so it allocates any required memory under the hood automatically. If the host or GPU system memory is not enough, an error is returned.
2.5.2.1. cusolverSp<t>csrlsvlu()

cusolverStatus_t
cusolverSpScsrlsvlu[Host](cusolverSpHandle_t handle,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    const float *csrValA,
    const int *csrRowPtrA,

cusolverStatus_t
cusolverSpZcsrlsvlu[Host](cusolverSpHandle_t handle,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    const cuDoubleComplex *csrValA,
    const int *csrRowPtrA,
    const int *csrColIndA,
    const cuDoubleComplex *b,
    double tol,
    int reorder,
    cuDoubleComplex *x,
    int *singularity);
This function solves the linear system

\[ A \cdot x = b \]

\( A \) is an \( n \times n \) sparse matrix that is defined in CSR storage format by the three arrays \( \text{csrValA} \), \( \text{csrRowPtrA} \), and \( \text{csrColIndA} \). \( b \) is the right-hand-side vector of size \( n \), and \( x \) is the solution vector of size \( n \).

The supported matrix type is \text{CUSPARSE\_MATRIX\_TYPE\_GENERAL}. If matrix \( A \) is symmetric/Hermitian and only lower/upper part is used or meaningful, the user has to extend the matrix into its missing upper/lower part, otherwise the result would be wrong.

The linear system is solved by sparse LU with partial pivoting,

\[ P \cdot A = L \cdot U \]

\text{cusolver} library provides three reordering schemes, \text{symrcm}, \text{symamd}, and \text{csrmetisnd} to reduce zero fill-in which dramatically affects the performance of LU factorization. The input parameter \text{reorder} can enable \text{symrcm} (\text{symamd} or \text{csrmetisnd}) if \text{reorder} is 1 (2, or 3), otherwise, no reordering is performed.

If \text{reorder} is nonzero, \text{csrlsvlu} does

\[ P \cdot A \cdot Q^T = L \cdot U \]

where \( Q = \text{symrcm}(A + A^T) \).

If \( A \) is singular under given tolerance \( (\text{max}(\text{tol}, 0)) \), then some diagonal elements of \( U \) is zero, i.e.

\[ |U(j,j)| < \text{tol} \text{ for some } j \]

The output parameter \text{singularity} is the smallest index of such \( j \). If \( A \) is non-singular, \text{singularity} is -1. The index is base-0, independent of base index of \( A \). For example, if 2nd column of \( A \) is the same as first column, then \( A \) is singular and \text{singularity} = 1 which means \( U(1,1) \approx 0 \).

Remark 1: \text{csrlsvlu} performs traditional LU with partial pivoting, the pivot of k-th column is determined dynamically based on the k-th column of intermediate matrix. \text{csrlsvlu} follows Gilbert and Peierls's algorithm [4] which uses depth-first-search and topological ordering to solve triangular system (Davis also describes this algorithm in detail in his book [1]). since cuda 10.1, \text{csrlsvlu} will incrementally reallocate the memory to store \( L \) and \( U \). This feature can avoid over-estimate size from QR factorization. In some cases, zero fill-in of QR can be order of magnitude higher than LU.

Remark 2: only CPU (Host) path is provided.

    int nnz,
    const cusparseMatDescr_t descrA,
    const cuDoubleComplex *csrVal,
    const int *csrRowPtr,
    const int *csrColInd,
    const cuDoubleComplex *b,
    double tol,
    int reorder,
    cuDoubleComplex *x,
    int *singularity);
```
This function solves the linear system

\[ A^*x = b \]

\( A \) is an \( m \times m \) symmetric positive definite sparse matrix that is defined in CSR storage format by the three arrays \( csrValA, csrRowPtrA, \) and \( csrColIndA \). \( b \) is the right-hand-side vector of size \( m \), and \( x \) is the solution vector of size \( m \).

The supported matrix type is \texttt{CUSPARSE\_MATRIX\_TYPE\_GENERAL} and upper triangular part of \( A \) is ignored (if parameter \texttt{reorder} is zero). In other words, suppose input matrix \( A \) is decomposed as \( A = L + D + U \), where \( L \) is lower triangular, \( D \) is diagonal and \( U \) is upper triangular. The function would ignore \( U \) and regard \( A \) as a symmetric matrix with the formula \( A = L + D + L^H \). If parameter \texttt{reorder} is nonzero, the user has to extend \( A \) to a full matrix, otherwise the solution would be wrong.

The linear system is solved by sparse Cholesky factorization, \n
\[ A = G^*G^H \]

where \( G \) is the Cholesky factor, a lower triangular matrix.

The output parameter \texttt{singularity} has two meanings:

- If \( A \) is not positive definite, there exists some integer \( k \) such that \( A(0:k, 0:k) \) is not positive definite. \texttt{singularity} is the minimum of such \( k \).
- If \( A \) is positive definite but near singular under tolerance \( \max(\text{tol}, 0) \), i.e. there exists some integer \( k \) such that \( G(k,k) \leq \text{tol} \). \texttt{singularity} is the minimum of such \( k \).

\texttt{singularity} is base-0. If \( A \) is positive definite and not near singular under tolerance, \texttt{singularity} is -1. If the user wants to know if \( A \) is positive definite or not, \text{tol}=0 is enough.

\texttt{cusolver} library provides three reordering schemes, \texttt{symrcm}, \texttt{symamd}, and \texttt{csrmetisnd} to reduce zero fill-in which dramatically affects the performance of Cholesky factorization. The input parameter \texttt{reorder} can enable \texttt{symrcm} (\texttt{symamd} or \texttt{csrmetisnd}) if \texttt{reorder} is 1 (2, or 3), otherwise, no reordering is performed.

Remark 1: the function works for in-place (\( x \) and \( b \) point to the same memory block) and out-of-place.

Remark 2: the function only works on 32-bit index, if matrix \( G \) has large zero fill-in such that number of nonzeros is bigger than \( 2^{31} \), then \texttt{CUSOLVER\_STATUS\_ALLOC\_FAILED} is returned.

**Input**

```

This function solves the following least-square problem

$$ x = \arg \min_{x} \| A x - b \| $$

$A$ is an $m \times n$ sparse matrix that is defined in CSR storage format by the three arrays $\text{csrValA}$, $\text{csrRowPtrA}$, and $\text{csrColIndA}$. $b$ is the right-hand-side vector of size $m$, and $x$ is the least-square solution vector of size $n$.

The supported matrix type is $\text{CUSPARSE_MATRIX_TYPE_GENERAL}$. If $A$ is square, symmetric/Hermitian and only lower/upper part is used or meaningful, the user has to extend the matrix into its missing upper/lower part, otherwise the result is wrong.

This function only works if $m$ is greater or equal to $n$, in other words, $A$ is a tall matrix.

The least-square problem is solved by sparse QR factorization with column pivoting,

$$ A^T P = Q R $$

If $A$ is of full rank (i.e. all columns of $A$ are linear independent), then matrix $P$ is an identity. Suppose rank of $A$ is $k$, less than $n$, the permutation matrix $P$ reorders columns of $A$ in the following sense:

$$ A^T P = (A_1 \ A_2) (Q_1 \ Q_2) \begin{bmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{bmatrix} $$
where \( R_{11} \) and \( A \) have the same rank, but \( R_{22} \) is almost zero, i.e. every column of \( A_2 \) is linear combination of \( A_1 \).

The input parameter \( \text{tol} \) decides numerical rank. The absolute value of every entry in \( R_{22} \) is less than or equal to \( \text{tol} = \max(\text{tol}, 0) \).

The output parameter \( \text{rankA} \) denotes numerical rank of \( A \).

Suppose \( y = P^*x \) and \( c = Q^H*b \), the least square problem can be reformed by

\[
\min ||A^*x - b|| = \min ||R^*y - c||
\]

or in matrix form

\[
\begin{pmatrix}
R_{11} & R_{12} \\
R_{21} & R_{22}
\end{pmatrix}
\begin{pmatrix}
y_1 \\
y_2
\end{pmatrix} =
\begin{pmatrix}
c_1 \\
c_2
\end{pmatrix}
\]

The output parameter \( \text{min_norm} \) is \( ||c_2|| \), which is minimum value of least-square problem.

If \( A \) is not of full rank, above equation does not have a unique solution. The least-square problem is equivalent to

\[
\min ||y||
\text{subject to } R_{11}^*y_1 + R_{12}^*y_2 = c_1
\]

Or equivalently another least-square problem

\[
\min \left\| \begin{pmatrix} R_{11} & R_{12} \\ I & \end{pmatrix} y_2 - \begin{pmatrix} R_{11} \\ O \end{pmatrix} c_1 \right\|
\]

The output parameter \( x \) is \( P^T*y \), the solution of least-square problem.

The output parameter \( p \) is a vector of size \( n \). It corresponds to a permutation matrix \( P \). \( p(i) = j \) means \( (P^*x)(i) = x(j) \). If \( A \) is of full rank, \( p = 0:n-1 \).

Remark 1: \( p \) is always base 0, independent of base index of \( A \).

Remark 2: only CPU (Host) path is provided.

   cuDoubleComplex mu0,
   const cuDoubleComplex *x0,
   int maxite,
   double tol,
   cuDoubleComplex *mu,
   cuDoubleComplex *x);
```

This function solves the simple eigenvalue problem \( A \mathbf{x} = \lambda \mathbf{x} \) by shift-inverse method.

\( A \) is an \( m \times m \) sparse matrix that is defined in CSR storage format by the three arrays \( csrValA, csrRowPtrA \), and \( csrColIndA \). The output parameter \( x \) is the approximated eigenvector of size \( m \).

The following shift-inverse method corrects eigenpair step-by-step until convergence.

It accepts several parameters:

- \( \text{mu0} \) is an initial guess of eigenvalue. The shift-inverse method will converge to the eigenvalue \( \text{mu} \) nearest \( \text{mu0} \) if \( \text{mu} \) is a singleton. Otherwise, the shift-inverse method may not converge.

- \( \text{x0} \) is an initial eigenvector. If the user has no preference, just chose \( \text{x0} \) randomly. \( \text{x0} \) must be nonzero. It can be non-unit length.

- \( \text{tol} \) is the tolerance to decide convergence. If \( \text{tol} \) is less than zero, it would be treated as zero.

- \( \text{maxite} \) is maximum number of iterations. It is useful when shift-inverse method does not converge because the tolerance is too small or the desired eigenvalue is not a singleton.

**Shift-Inverse Method**
Given a initial guess of eigenvalue $\mu_0$ and initial vector $x_0$ of unit length

$$x(0) = x_0$$

for $j = 0 : \text{maxite}$

$$\text{solve } (A - \mu_0 I)x(k+1) \text{ to unit length}$$

$$\text{normalize } x(k+1) \text{ to unit length}$$

compute approx. eigenvalue $\mu = x^H \cdot A \cdot x(k+1)$

if $||$ $\mu$ $||$ $> \mu_0$ and $|\mu| > \text{eps}$

endfor

The supported matrix type is \texttt{CUSPARSE\_MATRIX\_TYPE\_GENERAL}. If \textbf{A} is symmetric/Hermitian and only lower/upper part is used or meaningful, the user has to extend the matrix into its missing upper/lower part, otherwise the result is wrong.

Remark 1: \texttt{cu|h|solver[S|D]csreigvsi} only allows $\mu_0$ as a real number. This works if \textbf{A} is symmetric. Otherwise, the non-real eigenvalue has a conjugate counterpart on the complex plan, and shift-inverse method would not converge to such eigenvalue even the eigenvalue is a singleton. The user has to extend \textbf{A} to complex number and call \texttt{cu|h|solver[C|Z]csreigvsi} with $\mu_0$ not on real axis.

Remark 2: the tolerance $\texttt{tol}$ should not be smaller than $|\mu_0|*\text{eps}$, where eps is machine zero. Otherwise, shift-inverse may not converge because of small tolerance.

  const int *csrRowPtrA,
  const int *csrColIndA,
  cuDoubleComplex left_bottom_corner,
  cuDoubleComplex right_upper_corner,
  int *num_eigs);
\end{verbatim}

This function computes number of algebraic eigenvalues in a given box \( \mathbf{B} \) by contour integral

\[
\text{number of algebraic eigenvalues in box } \mathbf{B} = \frac{1}{2\pi \sqrt{1-\rho'(\zeta)}} \int_{c} \frac{\rho'(\zeta)}{\rho(\zeta)} \, d\zeta
\]
where closed line \( C \) is boundary of the box \( B \) which is a rectangle specified by two points, one is left bottom corner (input parameter \texttt{left\_bottom\_corner}) and the other is right upper corner (input parameter \texttt{right\_upper\_corner}). \( P(z) = \det(A - zI) \) is the characteristic polynomial of \( A \).

\( A \) is an \( m \times m \) sparse matrix that is defined in CSR storage format by the three arrays \texttt{csrValA}, \texttt{csrRowPtrA}, and \texttt{csrColIndA}.

The output parameter \texttt{num\_eigs} is number of algebraic eigenvalues in the box \( B \). This number may not be accurate due to several reasons:

1. the contour \( C \) is close to some eigenvalues or even passes through some eigenvalues.
2. the numerical integration is not accurate due to coarse grid size. The default resolution is 1200 grids along contour \( C \) uniformly.

Even though \texttt{csreigs} may not be accurate, it still can give the user some idea how many eigenvalues in a region where the resolution of disk theorem is bad. For example, standard 3-point stencil of finite difference of Laplacian operator is a tridiagonal matrix, and disk theorem would show "all eigenvalues are in the interval \([0, 4*N^2/2]\)" where \( N \) is number of grids. In this case, \texttt{csreigs} is useful for any interval inside \([0, 4*N^2/2]\).

Remark 1: if \( A \) is symmetric in real or hermitian in complex, all eigenvalues are real. The user still needs to specify a box, not an interval. The height of the box can be much smaller than the width.

Remark 2: only CPU (Host) path is provided.

2.5.3. Low Level Function Reference

This section describes low level API of cuSolverSP, including symrcm and batched QR.

2.5.3.1. cusolverSpXcsrsymrcm()

```c
 cusolverStatus_t
cusolverSpXcsrsymrcmHost(cusolverSpHandle_t handle,
 int n,
 int nnzA,
 const cusparseMatDescr_t descrA,
 const int *csrRowPtrA,
 const int *csrColIndA,
 int *p);
```

This function implements Symmetric Reverse Cuthill-McKee permutation. It returns a permutation vector \( p \) such that \( A(p,p) \) would concentrate nonzeros to diagonal. This is equivalent to `symrcm` in MATLAB, however the result may not be the same because of different heuristics in the pseudoperipheral finder. The `cuSolverSP` library implements `symrcm` based on the following two papers:

The output parameter \( p \) is an integer array of \( n \) elements. It represents a permutation array and it indexed using the base-0 convention. The permutation array \( p \) corresponds to a permutation matrix \( P \), and satisfies the following relation:
\[ A(p,p) = p^* A^* p^T \]

\( A \) is an \( n \times n \) sparse matrix that is defined in CSR storage format by the three arrays \( \text{csrValA} \), \( \text{csrRowPtrA} \), and \( \text{csrColIndA} \).

The supported matrix type is \text{CUSPARSE_MATRIX_TYPE_GENERAL}. Internally \( \text{rcm} \) works on \( A + A^T \), the user does not need to extend the matrix if the matrix is not symmetric.

Remark 1: only CPU (Host) path is provided.

2.5.3.2. cusolverSpXcsrsymmdq()

```c
 cusolverStatus_t
 cusolverSpXcsrsymmdqHost(cusolverSpHandle_t handle,
   int n,
   int nnzA,
   const cusparseMatDescr_t descrA,
   const int *csrRowPtrA,
   const int *csrColIndA,
   int *p);
```

This function implements Symmetric Minimum Degree Algorithm based on Quotient Graph. It returns a permutation vector $p$ such that $A(p,p)$ would have less zero fill-in during Cholesky factorization. The cuSolverSP library implements `symmdq` based on the following two papers:

The output parameter $p$ is an integer array of $n$ elements. It represents a permutation array with base-0 index. The permutation array $p$ corresponds to a permutation matrix $P$, and satisfies the following relation:

$$A(p,p) = P^T A P$$

$A$ is an $n \times n$ sparse matrix that is defined in CSR storage format by the three arrays `csrValA`, `csrRowPtrA`, and `csrColIndA`.

The supported matrix type is `CUSPARSE_MATRIX_TYPE_GENERAL`. Internally `mdq` works on $A + A^T$, the user does not need to extend the matrix if the matrix is not symmetric.

Remark 1: only CPU (Host) path is provided.

2.5.3.3. cusolverSpXcsrsymamd()

cusolverStatus_t
cusolverSpXcsrsymamdHost(cusolverSpHandle_t handle,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    const int *csrRowPtrA,
    const int *csrColIndA,
    int *p);

This function implements Symmetric Approximate Minimum Degree Algorithm based on Quotient Graph. It returns a permutation vector p such that A(p,p) would have less zero fill-in during Cholesky factorization. The cuSolverSP library implements symamd based on the following paper:

The output parameter p is an integer array of n elements. It represents a permutation array with base-0 index. The permutation array p corresponds to a permutation matrix P, and satisfies the following relation:

\[ A(p,p) = P^*A^*P^T \]
A is an \( n \times n \) sparse matrix that is defined in CSR storage format by the three arrays \( \text{csrValA} \), \( \text{csrRowPtrA} \), and \( \text{csrColIndA} \).

The supported matrix type is \texttt{CUSPARSE\_MATRIX\_TYPE\_GENERAL}. Internally \texttt{amd} works on \( A + A^T \), the user does not need to extend the matrix if the matrix is not symmetric.

Remark 1: only CPU (Host) path is provided.

2.5.3.4. cusolverSpXcsrmetisnd()

cusolverStatus_t
cusolverSpXcsrmetisndHost(
    cusolverSpHandle_t handle,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    const int *csrRowPtrA,
    const int *csrColIndA,
    const int64_t *options,
    int *p);

This function is a wrapper of METIS_NodeND. It returns a permutation vector \( p \) such that \( A(p,p) \) would have less zero fill-in during nested dissection. The cuSolverSP library links libmetis_static.a which is 64-bit metis-5.1.0.

The parameter \( \text{options} \) is the configuration of metis. For those who do not have experiences of metis, set \( \text{options} = \text{NULL} \) for default setting.

The output parameter \( p \) is an integer array of \( n \) elements. It represents a permutation array with base-0 index. The permutation array \( p \) corresponds to a permutation matrix \( P \), and satisfies the following relation:

\[
A(p,p) = P^T A P
\]

\( A \) is an \( n \times n \) sparse matrix that is defined in CSR storage format by the three arrays \( \text{csrValA}, \text{csrRowPtrA}, \) and \( \text{csrColIndA} \).

The supported matrix type is \text{CUSPARSE_MATRIX_TYPE_GENERAL}. Internally \( \text{csrmetisnd} \) works on \( A + A^T \), the user does not need to extend the matrix if the matrix is not symmetric.

Remark 1: only CPU (Host) path is provided.

2.5.3.5. cusolverSpXcsrzd()  

```c
 cusolverStatus_t
cusolverSpXcsrzdHost(
    cusolverSpHandle_t handle,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    const float *csrValA,
    const int *csrRowPtrA,
    const int *csrColIndA,
    int *P,
    int *numnz)
```

This function implements MC21, zero-free diagonal algorithm. It returns a permutation vector \( p \) such that \( A(p,:) \) has no zero diagonal.

\( A \) is an \( n \times n \) sparse matrix that is defined in CSR storage format by the three arrays \( csrValA \), \( csrRowPtrA \), and \( csrColIndA \). The supported matrix type is \( \text{CUSPARSE_MATRIX_TYPE_GENERAL} \).
The output parameter \( p \) is an integer array of \( n \) elements. It represents a permutation array with base-0 index. The permutation array \( p \) corresponds to a permutation matrix \( P \), and satisfies the following relation:

\[
A(p,:) = P^* A
\]

The output parameter \( \text{numnz} \) describes number of nonzero diagonal in permutated matrix \( A(p,:) \). If \( \text{numnz} \) is less than \( n \), matrix \( A \) has structural singularity.

Remark 1: only CPU (Host) path is provided.

Remark 2: this routine does not maximize diagonal value of permuted matrix. The user cannot expect this routine can make "LU without pivoting" stable.

### 2.5.3.6. cusolverSpXcsrperm()

```c
cusolverStatus_t
cusolverSpXcsrperm_bufferSizeHost(cusolverSpHandle_t handle,
    int m,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    int *csrRowPtrA,
    int *csrColIndA,
    const int *p,
    const int *q,
    size_t *bufferSizeInBytes);
```

```c
cusolverStatus_t
cusolverSpXcsrpermHost(cusolverSpHandle_t handle,
    int m,
    int n,
    int nnzA,
    const cusparseMatDescr_t descrA,
    int *csrRowPtrA,
    int *csrColIndA,
    const int *p,
    const int *q,
    int *map,
    void *pBuffer);
```

Given a left permutation vector \( p \) which corresponds to permutation matrix \( P \) and a right permutation vector \( q \) which corresponds to permutation matrix \( Q \), this function computes permutation of matrix \( A \) by

\[
B = P^T A Q^T
\]

\( A \) is an \( m \times n \) sparse matrix that is defined in CSR storage format by the three arrays \( csrValA, csrRowPtrA \) and \( csrColIndA \).

The operation is in-place, i.e. the matrix \( A \) is overwritten by \( B \).

The permutation vector \( p \) and \( q \) are base 0. \( p \) performs row permutation while \( q \) performs column permutation. One can also use MATLAB command \( B = A(p,q) \) to permute matrix \( A \).

This function only computes sparsity pattern of \( B \). The user can use parameter \( \text{map} \) to get \( csrValB \) as well. The parameter \( \text{map} \) is an input/output. If the user sets \( \text{map}=0:1: (nnzA-1) \) before calling \( csrperm, csrValB=csrValA(map) \).

The supported matrix type is \text{CUSPARSE_MATRIX_TYPE_GENERAL}. If \( A \) is symmetric and only lower/upper part is provided, the user has to pass \( A + A^T \) into this function.
This function requires a buffer size returned by `csrperm_bufferSize()`. The address of `pBuffer` must be a multiple of 128 bytes. If it is not, `CUSOLVER_STATUS_INVALID_VALUE` is returned.

For example, if matrix \( A \) is

\[
A = \begin{pmatrix}
1.0 & 2.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
7.0 & 8.0 & 9.0
\end{pmatrix}
\]

and left permutation vector \( p = (0, 2, 1) \), right permutation vector \( q = (2, 1, 0) \), then \( P^*A^*Q^T \) is

\[
P^*A^*Q^T = \begin{pmatrix}
3.0 & 2.0 & 1.0 \\
9.0 & 8.0 & 7.0 \\
6.0 & 5.0 & 4.0
\end{pmatrix}
\]

Remark 1: only CPU (Host) path is provided.

Remark 2: the user can combine `csrsymrcm` and `csrperm` to get \( P^*A^*P^T \) which has less zero fill-in during QR factorization.

```

The batched sparse QR factorization is used to solve either a set of least-squares problems

$$x_j = \text{argmin}_{z} \| A_j^*z - b_j \|_2, j = 1, 2, \ldots, \text{batchSize}$$

or a set of linear systems

$$A_jx_j = b_j, j = 1, 2, \ldots, \text{batchSize}$$

where each $A_j$ is a $m \times n$ sparse matrix that is defined in CSR storage format by the four arrays csrValA, csrRowPtrA and csrColIndA.

The supported matrix type is CUSPARSE_MATRIX_TYPE_GENERAL. If $A$ is symmetric and only lower/upper part is provided, the user has to pass $A + A^H$ into this function.

The prerequisite to use batched sparse QR has two-folds. First all matrices $A_j$ must have the same sparsity pattern. Second, no column pivoting is used in least-square problem, so the solution is valid only if $A_j$ is of full rank for all $j = 1, 2, \ldots, \text{batchSize}$. All matrices have the same sparsity pattern, so only one copy of csrRowPtrA and csrColIndA is used. But the array csrValA stores coefficients of $A_j$ one after another. In other words, csrValA[k*nnzA : (k+1)*nnzA] is the value of $A_k$.

The batched QR uses opaque data structure csrqrInfo to keep intermediate data, for example, matrix $Q$ and matrix $R$ of QR factorization. The user needs to create csrqrInfo first by cusolverSpCreateCsrqrInfo before any function in batched QR operation.
The csrqrInfo would not release internal data until cusolverSpDestroyCsrqrInfo is called.

There are three routines in batched sparse QR, cusolverSpXcsrqrAnalysisBatched, cusolverSp[S|D|C|Z]csrqrBufferInfoBatched and cusolverSp[S|D|C|Z]csrqrsvBatched.

First, cusolverSpXcsrqrAnalysisBatched is the analysis phase, used to analyze sparsity pattern of matrix $Q$ and matrix $R$ of QR factorization. Also parallelism is extracted during analysis phase. Once analysis phase is done, the size of working space to perform QR is known. However cusolverSpXcsrqrAnalysisBatched uses CPU to analyze the structure of matrix $A$, and this may consume a lot of memory. If host memory is not sufficient to finish the analysis, CUSOLVER_STATUS_ALLOC_FAILED is returned. The required memory for analysis is proportional to zero fill-in in QR factorization. The user may need to perform some kind of reordering to minimize zero fill-in, for example, colamd or symrcm in MATLAB. cuSolverSP library provides symrcm (cusolverSpXcsrsymrcm).

Second, the user needs to choose proper batchSize and to prepare working space for sparse QR. There are two memory blocks used in batched sparse QR. One is internal memory block used to store matrix $Q$ and matrix $R$. The other is working space used to perform numerical factorization. The size of the former is proportional to batchSize, and the size is specified by returned parameter internalDataInBytes of cusolverSp[S|D|C|Z]csrqrBufferInfoBatched. while the size of the latter is almost independent of batchSize, and the size is specified by returned parameter workspaceInBytes of cusolverSp[S|D|C|Z]csrqrsvBatched. The internal memory block is allocated implicitly during first call of cusolverSp[S|D|C|Z]csrqrsvBatched. The user only needs to allocate working space for cusolverSp[S|D|C|Z]csrqrsvBatched.

Instead of trying all batched matrices, the user can find maximum batchSize by querying cusolverSp[S|D|C|Z]csrqrBufferInfoBatched. For example, the user can increase batchSize till summation of internalDataInBytes and workspaceInBytes is greater than size of available device memory.

Suppose that the user needs to perform 253 linear solvers and available device memory is 2GB. if cusolverSp[S|D|C|Z]csrqrsvBatched can only afford batchSize 100, the user has to call cusolverSp[S|D|C|Z]csrqrsvBatched three times to finish all. The user calls cusolverSp[S|D|C|Z]csrqrBufferInfoBatched with batchSize 100. The opaque info would remember this batchSize and any subsequent call of cusolverSp[S|D|C|Z]csrqrsvBatched cannot exceed this value. In this example, the first two calls of cusolverSp[S|D|C|Z]csrqrsvBatched will use batchSize 100, and last call of cusolverSp[S|D|C|Z]csrqrsvBatched will use batchSize 53.
Example: suppose that $A_0, A_1, \ldots, A_9$ have the same sparsity pattern, the following code solves 10 linear systems $A_j x_j = b_j$, $j = 0, 2, \ldots, 9$ by batched sparse QR.

```c
// Suppose that $A_0, A_1, \ldots, A_9$ are $m \times m$ sparse matrix represented by CSR format, // Each matrix $A_j$ has nonzero $\text{nnz}_A$, and shares the same $\text{csrRowPtr}_A$ and $\text{csrColInd}_A$. // $\text{csrVal}_A$ is aggregation of $A_0, A_1, \ldots, A_9$. int m; // number of rows and columns of each $A_j$ int nnzA; // number of nonzeros of each $A_j$ int *csrRowPtrA; // each $A_j$ has the same csrRowPtrA int *csrColIndA; // each $A_j$ has the same csrColIndA double *csrValA; // aggregation of $A_0, A_1, \ldots, A_9$ cont int batchSize = 10; // 10 linear systems

cusolverSpHandle_t handle; // handle to cusolver library
 cusparseMatDescr_t descrA = NULL;
void *pBuffer = NULL; // working space for numerical factorization

// step 1: create a descriptor
cusparseCreateMatDescr(&descrA);
cusparseSetMatIndexBase(descrA, CUSPARSE_INDEX_BASE_ONE); // $A$ is base-1
cusparseSetMatType(descrA, CUSPARSE_MATRIX_TYPE_GENERAL); // $A$ is a general matrix

// step 2: create empty info structure
cusolverSpCreateCsrqrInfo(&info);

// step 3: symbolic analysis
cusolverSpXcsrqrAnalysisBatched(
    handle, m, m, nnzA,
    descrA, csrRowPtrA, csrColIndA, info);

// step 4: allocate working space for $A_j x_j = b_j$
cusolverSpDcsrqrBufferInfoBatched(
    handle, m, m, nnzA,
    descrA, csrValA, csrRowPtrA, csrColIndA,
    batchSize,
    info,
    &internalDataInBytes,
    &workspaceInBytes);

cudaMalloc(&pBuffer, workspaceInBytes);

// step 5: solve $A_j x_j = b_j$
cusolverSpDcsrqrsvBatched(
    handle, m, m, nnzA,
    descrA, csrValA, csrRowPtrA, csrColIndA,
    b,
    x,
    batchSize,
    info,
    pBuffer);

// step 7: destroy info
cusolverSpDestroyCsrqrInfo(info);
```

Please refer to Appendix B for detailed examples.

Remark 1: only GPU (device) path is provided.

### CUSOLVER_STATUS_ARCH_MISMATCH

The device only supports compute capability 2.0 and above.

### CUSOLVER_STATUS_INTERNAL_ERROR

An internal operation failed.

### CUSOLVER_STATUS_MATRIX_TYPE_NOT_SUPPORTED

The matrix type is not supported.

---

#### 2.6. cuSolverRF: Refactorization Reference

This chapter describes API of cuSolverRF, a library for fast refactorization.

#### 2.6.1. cusolverRfAccessBundledFactors()

```c

cusolverStatus_t
cusolverRfAccessBundledFactors(/* Input */
    cusolverRfHandle_t handle,
    /* Output (in the host memory) */
    int* nnzM,
    /* Output (in the device memory) */
    int** Mp,
    int** Mi,
    double** Mx);
```

This routine allows direct access to the lower $L$ and upper $U$ triangular factors stored in the cuSolverRF library handle. The factors are compressed into a single matrix $M = (L - I) + U$, where the unitary diagonal of $L$ is not stored. It is assumed that a prior call to the `cusolverRfRefactor()` was done in order to generate these triangular factors.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>the handle to the cuSolverRF library.</td>
</tr>
<tr>
<td>nnzM</td>
<td>host</td>
<td>output</td>
<td>the number of non-zero elements of matrix $M$.</td>
</tr>
<tr>
<td>Mp</td>
<td>device</td>
<td>output</td>
<td>the array of offsets corresponding to the start of each row in the arrays $Mi$ and $Mx$. This array has also an extra entry at the end that stores the number of non-zero elements in the matrix $SM$. The array size is $n+1$.</td>
</tr>
<tr>
<td>Mi</td>
<td>device</td>
<td>output</td>
<td>the array of column indices corresponding to the non-zero elements in the matrix $M$. It is assumed that this array is sorted by row and by column within each row. The array size is $nnzM$.</td>
</tr>
<tr>
<td>Mx</td>
<td>device</td>
<td>output</td>
<td>the array of values corresponding to the non-zero elements in the matrix $M$. It is assumed that this array is sorted by row and by column within each row. The array size is $nnzM$.</td>
</tr>
</tbody>
</table>

**Status Returned**
CUSOLVER_STATUS_SUCCESS | the operation completed successfully.
CUSOLVER_STATUS_NOT_INITIALIZED | the library was not initialized.
CUSOLVER_STATUS_EXECUTION_FAILED | a kernel failed to launch on the GPU.

### 2.6.2. cusolverRfAnalyze()

```c
cusolverStatus_t cusolverRfAnalyze(cusolverRfHandle_t handle);
```

This routine performs the appropriate analysis of parallelism available in the LU refactorization depending upon the algorithm chosen by the user.

\[
A = L^* U
\]

It is assumed that a prior call to the `cusolverRfSetup[Host|Device]()` was done in order to create internal data structures needed for the analysis.

This routine needs to be called only once for a single linear system

\[
A_l x_i = f_i
\]

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>in/out</td>
<td>the handle to the cuSolverRF library.</td>
</tr>
</tbody>
</table>

### Status Returned

<table>

<td>an internal operation failed.</td>
</tr>
</tbody>
</table>
2.6.3. cusolverRfSetupDevice()

cusolverStatus_t
cusolverRfSetupDevice(/* Input (in the device memory) */
int n,
int nnzA,
int* csrRowPtrA,
int* csrColIndA,
double* csrValA,
int nnzL,
int* csrRowPtrL,
int* csrColIndL,
double* csrValL,
int nnzU,
int* csrRowPtrU,
int* csrColIndU,
double* csrValU,
int* P,
int* Q,
/* Output */
cusolverRfHandle_t handle);

This routine assembles the internal data structures of the cuSolverRF library. It is often
the first routine to be called after the call to the cusolverRfCreate() routine.

This routine accepts as input (on the device) the original matrix A, the lower (L) and
upper (U) triangular factors, as well as the left (P) and the right (Q) permutations
resulting from the full LU factorization of the first (i=1) linear system

\[ A_i x_i = f_i \]

The permutations P and Q represent the final composition of all the left and right
reorderings applied to the original matrix A, respectively. However, these permutations
are often associated with partial pivoting and reordering to minimize fill-in, respectively.

This routine needs to be called only once for a single linear system

\[ A_i x_i = f_i \]

#### cusolverRfCreate()

- **h_csrValU**: Host input
  - The array of values corresponding to the non-zero elements in the matrix \( U \). It is assumed that this array is sorted by row and by column within each row. The array size is \( nnzU \).

- **h_P**: Host input
  - The left permutation (often associated with pivoting). The array size in \( n \).

- **h_Q**: Host input
  - The right permutation (often associated with reordering). The array size in \( n \).

- **handle**: Host output
  - The handle to the cuSolverRF library.
2.6.6. cusolverRfExtractBundledFactorsHost()

cusolverStatus_t
cusolverRfExtractBundledFactorsHost(/* Input */
cusolverRfHandle_t handle,
/* Output (in the host memory) */
int* h_nnzM,
int** h_Mp,
int** h_Mi,
double** h_Mx);

This routine extracts lower (L) and upper (U) triangular factors from the cuSolverRF library handle into the host memory. The factors are compressed into a single matrix $M = (L-I) + U$, where the unitary diagonal of (L) is not stored. It is assumed that a prior call to the cusolverRfRefactor() was done in order to generate these triangular factors.

</tbody>
</table>

#### 2.6.8. cusolverRfDestroy()

cusolverStatus_t cusolverRfDestroy(cusolverRfHandle_t handle);

This routine shuts down the cuSolverRF library. It releases acquired resources and must be called after all the cuSolverRF library routines.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>

</tr>
</tbody>
</table>

#### 2.6.9. cusolverRfGetMatrixFormat()

cusolverStatus_t cusolverRfGetMatrixFormat(cusolverRfHandle_t handle, cusolverRfMatrixFormat_t *format, cusolverRfUnitDiagonal_t *diag);

This routine gets the matrix format used in the cusolverRfSetupDevice(), cusolverRfSetupHost(), cusolverRfResetValues(), cusolverRfExtractBundledFactorsHost() and cusolverRfExtractSplitFactorsHost() routines.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>

</tr>
</tbody>
</table>
2.6.10. cusolverRfGetNumericProperties()

cusolverStatus_t
cusolverRfGetNumericProperties(cusolverRfHandle_t handle,
    double *zero,
    double *boost);

This routine gets the numeric values used for checking for "zero" pivot and for boosting it in the cusolverRfRefactor() and cusolverRfSolve() routines. The numeric boosting will be used only if boost > 0.0.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>

<td>the value which is substituted for zero pivot (if the later is flagged).</td>
</tr>
</tbody>
</table>

2.6.11. cusolverRfGetNumericBoostReport()

cusolverStatus_t
cusolverRfGetNumericBoostReport(cusolverRfHandle_t handle,
    cusolverRfNumericBoostReport_t *report);

This routine gets the report whether numeric boosting was used in the cusolverRfRefactor() and cusolverRfSolve() routines.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
2.6.12. cusolverRfGetResetValuesFastMode()

cusolverStatus_t
cusolverRfGetResetValuesFastMode(cusolverRfHandle_t handle, 
rfResetValuesFastMode_t *fastMode);

This routine gets the mode used in the cusolverRfResetValues routine.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>

</tbody>
</table>

2.6.13. cusolverRfGet_Algs()

cusolverStatus_t
cusolverRfGet_Algs(cusolverRfHandle_t handle, 
cusolverRfFactorization_t* fact_alg, 
cusolverRfTriangularSolve_t* solve_alg);

This routine gets the algorithm used for the refactorization in cusolverRfRefactor() and the triangular solve in cusolverRfSolve().

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>the handle to the cuSolverRF library.</td>

<td>the library was not initialized.</td>
</tr>
</tbody>
</table>

2.6.14. cusolverRfRefactor()

cusolverStatus_t cusolverRfRefactor(cusolverRfHandle_t handle);

This routine performs the LU re-factorization

\[ A = L^*U \]

exploring the available parallelism on the GPU. It is assumed that a prior call to the glu_analyze() was done in order to find the available parallelism.
This routine may be called multiple times, once for each of the linear systems

\[ A_i x_i = f_i \]

There are some constraints to the combination of algorithms used for refactorization and solving routines, `cusolverRfRefactor()` and `cusolverRfSolve()`. The wrong combination generates the error code `CUSOLVER_STATUS_INVALID_VALUE`. The table below summarizes the supported combinations of algorithms:

**Compatible algorithms for solving and refactorization routines.**

<table>
<thead>
<tr>
<th>Factorization</th>
<th>Solving</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVERRF_FACTORIZATION_ALG0</td>
<td>TRIANGULAR_SOLVE_ALG1</td>

</tbody>
</table>

2.6.15. `cusolverRfResetValues()`

```c
cusolverStatus_t
cusolverRfResetValues(/* Input (in the device memory) */
    int n,
    int nnzA,
    int* csrRowPtrA,
    int* csrColIndA,
    double* csrValA,
    int* P,
    int* Q,
    /* Output */
    cusolverRfHandle_t handle);
```

This routine updates internal data structures with the values of the new coefficient matrix. It is assumed that the arrays `csrRowPtrA`, `csrColIndA`, `P` and `Q` have not changed since the last call to the `cusolverRfSetup[Host|Device]` routine. This assumption reflects the fact that the sparsity pattern of coefficient matrices as well as reordering to minimize fill-in and pivoting remain the same in the set of linear systems

\[ A_i x_i = f_i \]
This routine may be called multiple times, once for each of the linear systems

\[ A_i x_i = f_i \]

<table>
<thead>
<tr>
<th>parameter</th>

</tr>
</tbody>
</table>

**Status Returned**

| CUSOLVER_STATUS_SUCCESS       | the operation completed successfully. |
| CUSOLVER_STATUS_NOT_INITIALIZED | the library was not initialized. |
| CUSOLVER_STATUS_INVALID_VALUE  | an unsupported value or parameter was passed. |
| CUSOLVER_STATUS_EXECUTION_FAILED | a kernel failed to launch on the GPU. |

### 2.6.16. cusolverRfSetMatrixFormat()

cusolverStatus_t

```
cusolverRfSetMatrixFormat(cusolverRfHandle_t handle, gluMatrixFormat_t format, gluUnitDiagonal_t diag);
```

This routine sets the matrix format used in the `cusolverRfSetupDevice()`, `cusolverRfSetupHost()`, `cusolverRfResetValues()`, `cusolverRfExtractBundledFactorsHost()` and
cusolverRfExtractSplitFactorsHost() routines. It may be called once prior to cusolverRfSetupDevice() and cusolverRfSetupHost() routines.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>

<td>the library was not initialized.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_INVALID_VALUE</td>
<td>an enumerated mode parameter is wrong.</td>
</tr>
</tbody>
</table>

2.6.17. cusolverRfSetNumericProperties()

cusolverStatus_t
cusolverRfSetNumericProperties(cusolverRfHandle_t handle,
        double zero,
        double boost);

This routine sets the numeric values used for checking for "zero" pivot and for boosting it in the cusolverRfRefactor() and cusolverRfSolve() routines. It may be called multiple times prior to cusolverRfRefactor() and cusolverRfSolve() routines. The numeric boosting will be used only if boost > 0.0.

<table>
<thead>
<tr>
<th>parameter</th>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
</tbody>
</table>

2.6.18. cusolverRfSetResetValuesFastMode()

cusolverStatus_t
cusolverRfSetResetValuesFastMode(cusolverRfHandle_t handle,
        gluResetValuesFastMode_t fastMode);

This routine sets the mode used in the cusolverRfResetValues routine. The fast mode requires extra memory and is recommended only if very fast calls
to `cusolverRfResetValues()` are needed. It may be called once prior to `cusolverRfAnalyze()` routine.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>the handle to the cuSolverRF library.</td>
</tr>
<tr>
<td>fastMode</td>
<td>host</td>
<td>input</td>
<td>the enumerated mode type.</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the operation completed successfully.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_INVALID_VALUE</td>
<td>an enumerated mode parameter is wrong.</td>
</tr>
</tbody>
</table>

2.6.19. `cusolverRfSetAlgs()`

```c
cusolverStatus_t
cusolverRfSetAlgs(cusolverRfHandle_t handle,
                    gluFactorization_t fact_alg,
                    gluTriangularSolve_t alg);
```

This routine sets the algorithm used for the refactorization in `cusolverRfRefactor()` and the triangular solve in `cusolverRfSolve()`. It may be called once prior to `cusolverRfAnalyze()` routine.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>input</td>
<td>the handle to the cuSolverRF library.</td>
</tr>
<tr>
<td>alg</td>
<td>host</td>
<td>input</td>
<td>the enumerated algorithm type.</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the operation completed successfully.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
</tbody>
</table>

2.6.20. `cusolverRfSolve()`

```c
cusolverStatus_t
cusolverRfSolve(/* Input (in the device memory) */
                  cusolverRfHandle_t handle,
                  int *P,
                  int *Q,
                  int nrhs,
                  double *Temp,
                  int ldt,
                  /* Input/Output (in the device memory) */
                  double *XF,
                  /* Input */
                  int ldxf);
```
This routine performs the forward and backward solve with the lower $L \in \mathbb{R}^{n \times n}$ and upper $U \in \mathbb{R}^{n \times n}$ triangular factors resulting from the LU re-factorization

$$A = L^* U$$

which is assumed to have been computed by a prior call to the `cusolverRfRefactor()` routine.

The routine can solve linear systems with multiple right-hand-sides (rhs),

$$AX = (LU)X = L(UX) = LY = F \text{ where } UX = Y$$

even though currently only a single rhs is supported.

This routine may be called multiple times, once for each of the linear systems

$$A_i x_i = f_i$$

<table>

<td>an internal operation failed.</td>
</tr>
</tbody>
</table>
2.6.21. `cusolverRFBatchSetupHost()`

```c
 cusolverStatus_t
cusolverRFBatchSetupHost(/* Input (in the host memory) */
  int batchSize,
  int n,
  int nnzA,
  int* h_csrRowPtrA,
  int* h_csrColIndA,
  double *h_csrValA_array[],
  int nnzL,
  int* h_csrRowPtrL,
  int* h_csrColIndL,
  double *h_csrValL,
  int nnzU,
  int* h_csrRowPtrU,
  int* h_csrColIndU,
  double *h_csrValU,
  int* h_P,
  int* h_Q,
  /* Output */
  cusolverRFHandle_t handle);
```

This routine assembles the internal data structures of the cuSolverRF library for batched operation. It is called after the call to the `cusolverRFCreate()` routine, and before any other batched routines.

The batched operation assumes that the user has the following linear systems

\[ A_j x_j = b_j, \quad j = 1, 2, ..., \text{batchSize} \]

where each matrix in the set \( \{A_j\} \) has the same sparsity pattern, and quite similar such that factorization can be done by the same permutation \( P \) and \( Q \). In other words, \( A_j, j > 1 \) is a small perturbation of \( A_1 \).

This routine accepts as input (on the host) the original matrix \( A \) (sparsity pattern and batched values), the lower (\( L \)) and upper (\( U \)) triangular factors, as well as the left (\( P \)) and the right (\( Q \)) permutations resulting from the full LU factorization of the first \( i=1 \) linear system

\[ A_1 x_1 = f_1 \]

The permutations \( P \) and \( Q \) represent the final composition of all the left and right reorderings applied to the original matrix \( A \), respectively. However, these permutations are often associated with partial pivoting and reordering to minimize fill-in, respectively.

Remark 1: the matrices \( A, L \) and \( U \) must be CSR format and base-0.

Remark 2: to get best performance, `batchSize` should be multiple of 32 and greater or equal to 32. The algorithm is memory-bound, once bandwidth limit is reached, there is no room to improve performance by large `batchSize`. In practice, `batchSize` of 32 - 128 is often enough to obtain good performance, but in some cases larger `batchSize` might be beneficial.
This routine needs to be called only once for a single linear system

\[ A_i x_i = f_i \]

### 2.6.22. cusolverRfBatchAnalyze()

```c
 cusolverStatus_t cusolverRfBatchAnalyze(cusolverRfHandle_t handle);
```

This routine performs the appropriate analysis of parallelism available in the batched LU re-factorization.

It is assumed that a prior call to the `cusolverRfBatchSetup[Host]()` was done in order to create internal data structures needed for the analysis.

This routine needs to be called only once for a single linear system

\[
A_{j}x_{j} = b_{j}, \ j = 1,2,\ldots, \text{batchSize}
\]

<table>
<thead>
<tr>
<th>parameter</th>

</tbody>
</table>
CUSOLVER_STATUS_SUCCESS the operation completed successfully.
CUSOLVER_STATUS_NOT_INITIALIZED the library was not initialized.
CUSOLVER_STATUS_EXECUTION_FAILED a kernel failed to launch on the GPU.
CUSOLVER_STATUS_ALLOC_FAILED an allocation of memory failed.
CUSOLVER_STATUS_INTERNAL_ERROR an internal operation failed.

2.6.23. cusolverRfBatchResetValues()

```
cusolverStatus_t
cusolverRfBatchResetValues(/* Input (in the device memory) */
    int batchSize,
    int n,
    int nnzA,
    int* csrRowPtrA,
    int* csrColIndA,
    double* csrValA_array[],
    int *P,
    int *Q,
    /* Output */
    cusolverRfHandle_t handle);
```

This routine updates internal data structures with the values of the new coefficient matrix. It is assumed that the arrays csrRowPtrA, csrColIndA, P and Q have not changed since the last call to the cusolverRfBatch_setup_host routine.

This assumption reflects the fact that the sparsity pattern of coefficient matrices as well as reordering to minimize fill-in and pivoting remain the same in the set of linear systems

\[ A_j x_j = b_j, \ j = 1, 2, \ldots, \text{batchSize} \]

The input parameter csrValA_array is an array of pointers on device memory. csrValA_array(j) points to matrix A_j which is also on device memory.

**2.6.24. cusolverRfBatchRefactor()**

cusolverStatus_t cusolverRfBatchRefactor(cusolverRfHandle_t handle);

This routine performs the LU re-factorization

\[
M_j = P_j^* A_j^* Q_j^T = L_j^* U_j
\]

exploring the available parallelism on the GPU. It is assumed that a prior call to the cusolverRfBatchAnalyze() was done in order to find the available parallelism.

Remark: cusolverRfBatchRefactor() would not report any failure of LU refactorization. The user has to call cusolverRfBatchZeroPivot() to know which matrix failed the LU refactorization.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>host</td>
<td>in/out</td>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_EXECUTION_FAILED</td>
<td>a kernel failed to launch on the GPU.</td>
</tr>
</tbody>
</table>
2.6.25. cusolverRfBatchSolve()

```c
cusolverStatus_t
cusolverRfBatchSolve(/* Input (in the device memory) */
    cusolverRfHandle_t handle,
    int *P,
    int *Q,
    int nrhs,
    double *Temp,
    int ldt,
    /* Input/Output (in the device memory) */
    double *XF_array[],
    /* Input */
    int ldxf);
```

To solve \(A_j x_j = b_j\), first we reform the equation by \(M_j Q^T x_j = P^* b_j\) where \(M_j = P^* A_j Q^T\). Then do refactorization \(M_j = L_j U_j\) by `cusolverRfBatch_Refactor()`. Further `cusolverRfBatch_Solve()` takes over the remaining steps, including:

\[
\begin{align*}
    z_j &= P^* b_j \\
    M_j^* y_j &= z_j \\
    x_j &= Q^T y_j
\end{align*}
\]

The input parameter `XF_array` is an array of pointers on device memory. `XF_array[j]` points to matrix \(x_j\) which is also on device memory.

Remark 1: only a single rhs is supported.

Remark 2: no singularity is reported during backward solve. If some matrix \(A_j\) failed the refactorization and \(U_j\) has some zero diagonal, backward solve would compute \(\text{NAN}\). The user has to call `cusolverRfBatch_Zero_Pivot` to check if refactorization is successful or not.

<table>
<thead>

</tr>
</tbody>
</table>
that contains the right-hand-sides $F$ and solutions $X$ (of size $ldxf*nrhs$).

| ldxf  | host | input | the leading dimension of dense matrix $XF$ ($ldxf >= n$). |

### Status Returned

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_SUCCESS</td>
<td>the operation completed successfully.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_NOT_INITIALIZED</td>
<td>the library was not initialized.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_INVALID_VALUE</td>
<td>an unsupported value or parameter was passed.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_EXECUTION_FAILED</td>
<td>a kernel failed to launch on the GPU.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_INTERNAL_ERROR</td>
<td>an internal operation failed.</td>
</tr>
</tbody>
</table>

#### 2.6.26. cusolverRfBatchZeroPivot()

```c
#include <cusolver.h>

cusolverStatus_t
cusolverRfBatchZeroPivot(/* Input */
    cusolverRfHandle_t handle
    /* Output (in the host memory) */
    int *position);
```

Although $A_j$ is close to each other, it does not mean $M_j = P^*A_j^*Q^T = L_j^*U_j$ exists for every $j$. The user can query which matrix failed LU refactorization by checking corresponding value in `position` array. The input parameter `position` is an integer array of size `batchSize`.

The j-th component denotes the refactorization result of matrix $A_j$. If `position(j)` is -1, the LU refactorization of matrix $A_j$ is successful. If `position(j)` is $k >= 0$, matrix $A_j$ is not LU factorizable and its matrix $U_j(j,j)$ is zero.

The return value of `cusolverRfBatch_Zero_Pivot` is

CUSOLVER_STATUS_ZERO_PIVOT if there exists one $A_j$ which failed LU refactorization.

The user can redo LU factorization to get new permutation $P$ and $Q$ if error code CUSOLVER_STATUS_ZERO_PIVOT is returned.

<table>
<thead>
<tr>
<th>parameter</th>
<th>MemSpace</th>

</tbody>
</table>
Chapter 3.
USING THE CUSOLVERMG API

3.1. General description
This chapter describes how to use the cuSolverMG library API. It is not a reference for the cuSolverMG API data types and functions; that is provided in subsequent chapters.

3.1.1. Thread Safety
The library is thread-safe only if one cuSolverMG context per thread.

3.1.2. Determinism
Currently all cuSolverMG API routines from a given toolkit version, generate the same bit-wise results when the following conditions are respected:

- all GPUs particating to the computation have the same compute-capabilities and the same number of SMs.
- the tiles size is kept the same between run.
- number of logical GPUs is kept the same. The order of GPUs are not important because all have the same compute-capabilities.

3.1.3. tile strategy
The tiling strategy of cuSolverMG is compatible with ScaLAPACK. The current release only supports 1-D column block cyclic, column-major PACKED format.

Figure 1.a shows a partition of the matrix $A$ of dimension $M_A$ by $N_A$. Each column tile has $T_A$ columns. There are seven columns tiles, labeled as 0,1,2,3,4,5,6, distributed into three GPUs in a cyclic way, i.e. each GPU takes one column tile in turn. For example, GPU 0 has column tile 0, 3, 6 (yellow tiles) and GPU 1 takes column tiles next to GPU 0 (blue tiles). Not all GPUs have the same number of tiles, in this example, GPU 0 has three tiles, others have only two tiles.
Using the CUSOLVERMG API

Figure 1.b shows two possible formats to store those column tiles locally in each GPU. Left side is called PACKED format and right side is UNPACKED format. PACKED format aggregates three column tiles in a contiguous memory block while UNPACKED format distributes these three column tiles into different memory blocks. The only difference between them is that PACKED format can have a big GEMM call instead of three GEMM calls in UNPACKED format. So theoretically speaking, PACKED format can deliver better performance than UNPACKED format. cusolveMG only supports PACKED format in the API. In order to achieve maximal performance, the user just needs to choose proper tile size $T_A$ to partition the matrix, not too small, for example 256 or above is enough.

There is another parameter, called $LLD_A$, to control the leading dimension of the local matrix in each GPU. $LLD_A$ must be greater or equal to $M_A$. The purpose of $LLD_A$ is for better performance of GEMM. For small problem, GEMM is faster if $LLD_A$ is power of 2. However for big problem, $LLD_A$ does not show significant improvement. cusolveMG only supports $LLD_A=M_A$.

Figure 1 Example of cusolveMG tiling for 3 Gpus

The processing grid in cusolveMG is a list of GPU IDs, similar to the process ID in ScalAPACK. cusolverMG only supports 1D column block cyclic, so only 1D grid is supported as well. Suppose deviceId is a list of GPU IDs, both deviceId=1,1,1 and deviceId=2,1,0 are valid. The former describes three logical devices are selected to run cusolveMG routines, and all have the same physical ID, 0. The latter still uses three logical devices, but each has different physical ID. The current design only accepts 32 logical devices, that is, the length of deviceId is less or equal to 32. Figure 1 uses deviceId=0,1,2.

In practice, the matrix A is distributed into GPUs listed in deviceId. If the user chooses deviceId=1,1,1, all columns tile are located in GPU 1, this will limit the size of the problem because of memory capacity of one GPU. Besides, multiGPU routine adds extra overhead on data communication through off-chip bus, which has big performance impact if NVLINK is not supported or used. It would be faster to run on single GPU instead of running multiGPU version with devices of the same GPU ID.
3.1.4. Global matrix versus local matrix

To operate a submatrix of the matrix \( A \) is simple in dense linear algebra, just shift the pointer to the starting point of the submatrix relative to \( A \). For example, \( \text{gesvd}(10,10, A) \) is SVD of \( A(0:9,0:9) \). \( \text{gesvd}(10,10, A + 5 + 2*\text{lda}) \) is SVD of 10-by-10 submatrix starting at \( A(5,2) \).

However it is not simple to operate on a submatrix of a distributed matrix because different starting point of the submatrix changes the distribution of the layout of that submatrix. \textit{ScaLAPACK} introduces two parameters, \( \text{IA} \) and \( \text{JA} \), to locate the submatrix. Figure 2 shows (global) matrix \( A \) of dimension \( M_A \) by \( N_A \). The sub\((A)\) is a \( M \) by \( N \) submatrix of \( A \), starting at \( \text{IA} \) and \( \text{JA} \). Please be aware that \( \text{IA} \) and \( \text{JA} \) are base-1.

Given a distributed matrix \( A \), the user can compute eigenvalues of the submatrix sub\((A)\) by either calling \( \text{syevd}(A, \text{IA}, \text{JA}) \) or gathering sub\((A)\) to another distributed matrix \( B \) and calling \( \text{syevd}(B, \text{IB}=1, \text{JB}=1) \).

![Figure 2 global matrix and local matrix](image)

3.1.5. usage of \_bufferSize

There is no cudaMalloc inside \textit{cuSolverMG} library, the user must allocate the device workspace explicitly. The routine \textit{xyz\_bufferSize} is to query the size of workspace of the routine \textit{xyz}, for example \( \text{xyz = syevd} \). To make the API simple, \textit{xyz\_bufferSize} follows almost the same signature of \textit{xyz} even it only depends on some parameters, for example, device pointer is not used to decide the size of workspace. In most cases, \textit{xyz\_bufferSize} is called in the beginning before actual device data (pointing by a device pointer) is prepared or before the device pointer is allocated. In such case, the user can pass null pointer to \textit{xyz\_bufferSize} without breaking the functionality.

\textit{xyz\_bufferSize} returns bufferSize for each device. The size is number of elements, not number of bytes.
3.1.6. synchronization

All routines are in synchronous (blocking call) manner. The data is ready after the routine. However the user has to prepare the distributed data before calling the routine. For example, if the user has multiple streams to setup the matrix, stream synchronization or device synchronization is necessary to guarantee distributed matrix is ready.

3.1.7. context switch

The user does not need to restore the device by cudaSetDevice() after each cuSolverMG call. All routines set the device back to what the caller has.

3.1.8. NVLINK

The peer-to-peer communication via NVLINK can dramatically reduce the overhead of data exchange among GPUs. cuSolverMG does not enable NVLINK implicitly, instead, it gives this option back to the user, not to interfere other libraries. The example code H.1 shows how to enable peer-to-peer communication.

3.2. cuSolverMG Types Reference

3.2.1. cuSolverMG Types

The float, double, cuComplex, and cuDoubleComplex data types are supported. The first two are standard C data types, while the last two are exported from cuComplex.h. In addition, cuSolverMG uses some familiar types from cuBlas.

3.2.2. cusolverMgHandle_t

This is a pointer type to an opaque cuSolverMG context, in which the user must initialize by calling cusolverMgCreate() prior to calling any other library function. An un-initialized handle object will lead to unexpected behavior, including crashes of cuSolverMG. The handle created and returned by cusolverMgCreate() must be passed to every cuSolverMG function.

3.2.3. cusolverMgGridMapping_t

The type indicates layout of grids.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUDALIBMGRID_MAPPING_ROW_MAJOR</td>
<td>row-major ordering.</td>
</tr>
<tr>
<td>CUDALIBMGRID_MAPPING_COL_MAJOR</td>
<td>column-major ordering.</td>
</tr>
</tbody>
</table>
3.2.4. cudaLibMgGrid_t
opaque structure of the distributed grid.

3.2.5. cudaLibMgMatrixDesc_t
opaque structure of the distributed matrix descriptor.

3.3. Helper Function Reference

3.3.1. cusolverMgCreate()

cusolverStatus_t
cusolverMgCreate(cusolverMgHandle_t *handle)

This function initializes the cuSolverMG library and creates a handle on the cuSolverMG context. It must be called before any other cuSolverMG API function is invoked. It allocates hardware resources necessary for accessing the GPU.

Output

| handle | the pointer to the handle to the cuSolverMG context. |

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the initialization succeeded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_ALLOC_FAILED</td>
<td>the resources could not be allocated.</td>
</tr>
</tbody>
</table>

3.3.2. cusolverMgDestroy()

cusolverStatus_t
cusolverMgDestroy( cusolverMgHandle_t handle)

This function releases CPU-side resources used by the cuSolverMG library.

Input

| handle | the handle to the cuSolverMG context. |

Status Returned

| CUSOLVER_STATUS_SUCCESS | the shutdown succeeded. |
3.3.3. cusolverMgDeviceSelect()

cusolverStatus_t
cusolverMgDeviceSelect(
    cusolverMgHandle_t handle,
    int nbDevices,
    int deviceId[] )

This function registers a subset of devices (GPUs) to cuSolverMG handle. Such subset of devices is used in subsequent API calls. The array deviceId contains a list of logical device ID. The term logical means repeated device ID are permitted. For example, suppose the user has only one GPU in the system, say device 0, if he sets deviceId=0,0,0, then cuSolverMG treats them as three independent GPUs, one stream each, so concurrent kernel launches still hold. The current design only supports up to 32 logical devices.

Input

<table>
<thead>
<tr>
<th>handle</th>
<th>the pointer to the handle to the cuSolverMG context.</th>
</tr>
</thead>
<tbody>
<tr>
<td>nbDevices</td>
<td>the number of logical devices</td>
</tr>
<tr>
<td>deviceId</td>
<td>an integer array of size nbDevices</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the initialization succeeded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_INVALID_VALUE</td>
<td>nbDevices must be greater than zero, and less or equal to 32.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_ALLOC_FAILED</td>
<td>the resources could not be allocated.</td>
</tr>
<tr>
<td>CUSOLVER_STATUS_INTERNAL_ERROR</td>
<td>internal error occurs when setting internal streams and events.</td>
</tr>
</tbody>
</table>

3.3.4. cusolverMgCreateDeviceGrid()

cusolverStatus_t
cusolverMgCreateDeviceGrid(
    cusolverMgGrid_t* grid,
    int32_t numRowDevices,
    int32_t numColDevices,
    const int32_t deviceId[],
    cusolverMgGridMapping_t mapping)

This function setups grid of devices.

Only 1-D column block cyclic is supported, so numRowDevices must be equal to 1.

WARNING: cusolverMgCreateDeviceGrid() must be consistent with cusolverMgDeviceSelect(), i.e. numColDevices must be equal to nbDevices in cusolverMgDeviceSelect().

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
</table>

www.nvidia.com
cuSOLVER Library
3.3.5. cusolverMgDestroyGrid()

cusolverStatus_t
cusolverMgDestroyGrid(
    cusolverMgGrid_t grid)

This function releases resources of a grid.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>grid</td>
<td>host</td>
<td>input/output</td>
<td>the pointer to the opaque structure.</td>
</tr>
</tbody>
</table>

Status Returned

<table>
<thead>
<tr>
<th>CUSOLVER_STATUS_SUCCESS</th>
<th>the operation completed successfully.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSOLVER_STATUS_INVALID_VALUE</td>
<td>numColDevices is not greater than 0. numRowDevices is not 1.</td>
</tr>
</tbody>
</table>

3.3.6. cusolverMgCreateMatDescr()

cusolverStatus_t
cusolverMgCreateMatrixDesc(
    cusolverMgMatrixDesc_t * desc,
    int64_t numRows,
    int64_t numCols,
    int64_t rowBlockSize,
    int64_t colBlockSize,
    cudaDataType_t dataType,
    const cusolverMgGrid_t grid)

This function setups the matrix descriptor desc.

Only 1-D column block cyclic is supported, so numRows must be equal to rowBlockSize.

<table>
<thead>
<tr>
<th>parameter</th>
<th>Memory</th>
<th>In/out</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>desc</td>
<td>host</td>
<td>output</td>
<td>the matrix descriptor.</td>

<tr>
<td>numRows</td>
<td>host</td>
<td>input</td>
<td>the number of rows of global A.</td>
</tr>
<tr>
<td>numCols</td>
<td>host</td>
<td>input</td>
<td>the number of columns of global A.</td>
</tr>
</tbody>
</table>
rowBlockSize | host | input | the number of rows per tile.
colBlockSize | host | input | the number of columns per tile.
dataType | host | input | data type of the matrix.
grid | host | input | the pointer to structure of grid.

Status Returned

| CUSOLVER_STATUS_SUCCESS | the operation completed successfully.
| CUSOLVER_STATUS_INVALID_VALUE | numRows, numCols, or rowBlockSize or colBlockSize is less than 0. numRows is not equal to rowBlockSize.

3.3.7. cusolverMgDestroyMatrixDesc()

cusolverStatus_t
cusolverMgDestroyMatrixDesc(
cusolverMgMatrixDesc_t desc)

This function releases the matrix descriptor desc.

desc | host | input/output | the matrix descriptor.

Status Returned

| CUSOLVER_STATUS_SUCCESS | the operation completed successfully.

3.4. Dense Linear Solver Reference

This chapter describes linear solver API of cuSolverMG.

3.4.1. cusolverMgPotrf()

The helper function below can calculate the sizes needed for pre-allocated buffer for cusolverMgPotrf.

cusolverStatus_t
cusolverMgPotrf_bufferSize(
cusolverMgHandle_t handle,
cublasFillMode_t upLo,
int N,
void *array_d_A[],
int IA,
int JA,
cudaLibMgMatrixDesc_t descrA,
cudaDataType computeType,
int64_t *lwork)
The routine below

```c
 cusolverStatus_t
cusolverMgPotrf(
   cusolverMgHandle_t handle,
   cublasFillMode_t uplo,
   int N,
   void *array_d_A[],
   int IA, int JA,
   cudaLibMgMatrixDesc_t descrA,
   cudaDataType computeType,
   void *array_d_work[],
   int64_t lwork, int *info)
```

computes the Cholesky factorization of a Hermitian positive-definite matrix using the
generic API interface.

A is a \( n \times n \) Hermitian matrix, only lower or upper part is meaningful. The input
parameter uplo indicates which part of the matrix is used. The function would leave
other part untouched.

If input parameter uplo is \texttt{CUBLAS\_FILL\_MODE\_LOWER}, only lower triangular part of \( A \)
is processed, and replaced by lower triangular Cholesky factor \( L \).

\[ A = L * L^H \]

If input parameter uplo is \texttt{CUBLAS\_FILL\_MODE\_UPPER}, only upper triangular part of \( A \)
is processed, and replaced by upper triangular Cholesky factor \( U \).

\[ A = U^H * U \]

The user has to provide device working space in array_d_work. array_d_work is a
host pointer array of dimension \( G \), where \( G \) is number of devices. array_d_work[j]
is a device pointer pointing to a device memory in j-th device. The data type of
array_d_work[j] is computeType. The size of array_d_work[j] is lwork which is
number of elements per device, returned by cusolverMgPotrf_bufferSize().

If Cholesky factorization failed, i.e. some leading minor of \( A \) is not positive definite,
or equivalently some diagonal elements of \( L \) or \( U \) is not a real number. The output
parameter info would indicate smallest leading minor of \( A \) which is not positive
definite.

If output parameter info = -i (less than zero), the i-th parameter is wrong (not
counting handle).

The generic API has two different types, \texttt{dataTypeA} is data type of the matrix \( A \),
computeType is compute type of the operation and data type of the workspace
(array_d_work) descrA contains \texttt{dataTypeA}, so there is no explicit parameter of
\texttt{dataTypeA}. cusolverMgPotrf only supports the following four combinations.

Appendix I provides an example of cusolverMgPotrf.
### Using the CUSOLVERMG API

<table>
<thead>

### 3.4.2. cusolverMgPotrs()

The helper function below can calculate the sizes needed for pre-allocated buffer for cusolverMgPotrs.

```c
 cusolverStatus_t
 cusolverMgPotrs_bufferSize(
     cusolverMgHandle_t handle,
     cublasFillMode_t uplo,
     int n,
     int nrhs,
     void *array_d_A[],
     int IA,
     int JA,
     cudaLibMgMatrixDesc_t descrA,
     void *array_d_B[],
     int IB,
     int JB,
     cudaLibMgMatrixDesc_t descrB,
     cudaDataType computeType,
     int64_t *lwork
 )
```

The routine bellow

```c
 cusolverStatus_t
 cusolverMgPotrs(
     cusolverMgHandle_t handle,
     cublasFillMode_t uplo,
     int n,
     int nrhs,
     void *array_d_A[],
     int IA,
     int JA,
     cudaLibMgMatrixDesc_t descrA,
     void *array_d_B[],
     int IB,
     int JB,
     cudaLibMgMatrixDesc_t descrB,
     cudaDataType computeType,
     void *array_d_work[],
     int64_t lwork,
     int *info)
```

This function solves a system of linear equations

\[
A^∗X = B
\]

where \( A \) is a \( nxn \) Hermitian matrix, only lower or upper part is meaningful using the generic API interface. The input parameter \( uplo \) indicates which part of the matrix is used. The function would leave other part untouched.
If input parameter `uplo` is `CUBLAS_FILL_MODE_LOWER`, the matrix should contain the lower triangular factor for Cholesky decomposition previously computed by `cusolverMgPotrf` routine.

\[ A = L^*L^H \]

If input parameter `uplo` is `CUBLAS_FILL_MODE_UPPER`, the matrix should contain the upper triangular factor for Cholesky decomposition previously computed by `cusolverMgPotrf` routine.

\[ A = U^*U \]

The operation is in-place, i.e. matrix `B` contains the solution of the linear system on exit.

If output parameter `info = -i` (less than zero), the `i`-th parameter is wrong (not counting handle).

The user has to provide device working space in `array_d_work`. `array_d_work` is a host pointer array of dimension `G`, where `G` is number of devices. `array_d_work[j]` is a device pointer pointing to a device memory in `j`-th device. The data type of `array_d_work[j]` is `computeType`. The size of `array_d_work[j]` is `lwork` which is number of elements per device, returned by `cusolverMgPotrs_bufferSize()`.

If output parameter `info = -i` (less than zero), the `i`-th parameter is wrong (not counting handle).

The generic API has four different types, `dataTypeA` is data type of the matrix `A`, `dataTypeB` is data type of the matrix `B`, `computeType` is compute type of the operation and data type of the workspace (`array_d_work`) `descrA` contains `dataTypeA` and `descrB` contains `dataTypeB` and so there is no explicit parameter of `dataTypeA` and `dataTypeB`. `cusolverMgPotrs` only supports the following four combinations.

Appendix I provides an example of `cusolverMgPotrs`.

</tbody>
</table>

### Status Returned

- **CUSOLVER_STATUS_SUCCESS**: the operation completed successfully.
- **CUSOLVER_STATUS_NOT_INITIALIZED**: the library was not initialized.
- **CUSOLVER_STATUS_INVALID_VALUE**: invalid parameters were passed (M, N<0).
- **CUSOLVER_STATUS_ARCH_MISMATCH**: the device only supports compute capability 2.0 and above.
- **CUSOLVER_STATUS_INTERNAL_ERROR**: an internal operation failed.
3.4.3. cusolverMgPotri()

The helper function below can calculate the sizes needed for pre-allocated buffer for cusolverMgPotri.

```c
cusolverStatus_t
cusolverMgPotri_bufferSize(
    cusolverMgHandle_t handle,
    cublasFillMode_t uplo,
    int N,
    void *array_d_A[],
    int IA,
    int JA,
    cudaLibMgMatrixDesc_t descrA,
    cudaDataType computeType,
    int64_t *lwork)
```

The routine below

```c
cusolverStatus_t
cusolverMgPotri(
    cusolverMgHandle_t handle,
    cublasFillMode_t uplo,
    int N,
    void *array_d_A[],
    int IA,
    int JA,
    cudaLibMgMatrixDesc_t descrA,
    cudaDataType computeType,
    void *array_d_work[],
    int64_t lwork,
    int *info)
```

This function computes the inverse of an Hermitian positive-definite matrix $A$ using the Cholesky factorization

$$A = L^*L^H = U^H*U$$

computed by cusolverMgPotrf().

If the input parameter `uplo` is `CUBLAS_FILL_MODE_LOWER`, on input, matrix $A$ contains the lower triangular factor of $A$ computed by cusolverMgPotrf. Only lower triangular part of $A$ is processed, and replaced by lower triangular part of the inverse of $A$.

If the input parameter `uplo` is `CUBLAS_FILL_MODE_UPPER`, on input, matrix $A$ contains the upper triangular factor of $A$ computed by cusolverMgPotrf. Only upper triangular part of $A$ is processed, and replaced by upper triangular part of the inverse of $A$.

The user has to provide device working space in `array_d_work`. `array_d_work` is a host pointer array of dimension $G$, where $G$ is number of devices. `array_d_work[j]` is a device pointer pointing to a device memory in j-th device. The data type of `array_d_work[j]` is `computeType`. The size of `array_d_work[j]` is `lwork` which is number of elements per device, returned by cusolverMgPotri_bufferSize().
If the computation of the inverse fails, i.e. some leading minor of $L$ or $U$, is null, the output parameter $info$ would indicate the smallest leading minor of $L$ or $U$ which is not positive definite.

If the output parameter $info = -i$ (less than zero), the $i$-th parameter is wrong (not counting the handle).

The generic API has two different types, $\text{dataTypeA}$ is data type of the matrix $A$, $\text{computeType}$ is compute type of the operation and data type of the workspace ($\text{array_d_work}$) $\text{descrA}$ contains $\text{dataTypeA}$, so there is no explicit parameter of $\text{dataTypeA}$. $\text{cusolverMgPotri}$ only supports the following four combinations.

Appendix I provides an example of $\text{cusolverMgPotri}$.

<table>

#### 3.4.4. cusolverMgGetrf()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
    cusolverStatus_t
    cusolverMgGetrf_bufferSize( 
        cusolverMgHandle_t handle, 
        int M, 
        int N, 
        void *array_d_A[], 
        int IA, 
        int JA, 
        cudaLibMgMatrixDesc_t descrA, 
        int *array_d_IPIV[], 
        cudaDataType_t computeType, 
        int64_t *lwork);
```

```c
    cusolverStatus_t
    cusolverMgGetrf( 
        cusolverMgHandle_t handle, 
        int M, 
        int N, 
        void *array_d_A[], 
        int IA, 
        int JA, 
        cudaLibMgMatrixDesc_t descrA, 
        int *array_d_IPIV[], 
        cudaDataType_t computeType, 
        void *array_d_work[], 
        int64_t lwork, 
        int *info );
```

This function computes the LU factorization of a $M \times N$ matrix

$$ P \cdot A = L \cdot U $$

www.nvidia.com

cuSOLVER Library
where \( A \) is a \( M \times N \) matrix, \( P \) is a permutation matrix, \( L \) is a lower triangular matrix with unit diagonal, and \( U \) is an upper triangular matrix.

The user has to provide device working space in \texttt{array\_d\_work}. \texttt{array\_d\_work} is a host pointer array of dimension \( G \), where \( G \) is number of devices. \texttt{array\_d\_work[j]} is a device pointer pointing to a device memory in \( j \)-th device. The data type of \texttt{array\_d\_work[j]} is \texttt{computeType}. The size of \texttt{array\_d\_work[j]} is \texttt{lwork} which is number of elements per device, returned by \texttt{cusolverMgGetrf\_bufferSize()}. If LU factorization failed, i.e. matrix \( A \) (\( U \)) is singular, The output parameter \texttt{info} = \( i \) indicates \( U(i,i) = 0 \).

If output parameter \texttt{info} = \( -i \) (less than zero), the \( i \)-th parameter is wrong (not counting handle).

If \texttt{array\_d\_IPIV} is null, no pivoting is performed. The factorization is \( A = L \times U \), which is not numerically stable.

\texttt{array\_d\_IPIV} must be consistent with \texttt{array\_d\_A}, i.e. \( J_A \) is the first column of \( \text{sub}(A) \), also the first column of \( \text{sub}(IPIV) \).

No matter LU factorization failed or not, the output parameter \texttt{array\_d\_IPIV} contains pivoting sequence, row \( i \) is interchanged with row \texttt{array\_d\_IPIV}(i).

The generic API has three different types, \texttt{dataTypeA} is data type of the matrix \( A \), \texttt{computeType} is compute type of the operation and data type of the workspace (\texttt{array\_d\_work}) \texttt{descrA} contains \texttt{dataTypeA}, so there is no explicit parameter of \texttt{dataTypeA}. \texttt{cusolverMgGetrf} only supports the following four combinations.

Appendix I provides an example of \texttt{cusolverMgGetrf}.

<table>
<thead>
<tr>

3.4.5. cusolverMgGetrs()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
cusolverStatus_t
cusolverMgGetrs_bufferSize(
    cusolverMgHandle_t handle,
    cublasOperation_t TRANS,
    int N,
    int NRHS,
    void *array_d_A[],
    int IA,
    int JA,
    cudaLibMgMatrixDesc_t descrA,
    int *array_d_IPIV[],
    void *array_d_B[],
    int IB,
    int JB,
    cudaLibMgMatrixDesc_t descrB,
    cudaDataType_t computeType,
    int64_t *lwork);
```

```c
cusolverStatus_t
cusolverMgGetrs(
    cusolverMgHandle_t handle,
    cublasOperation_t TRANS,
    int N,
    int NRHS,
    void *array_d_A[],
    int IA,
    int JA,
    cudaLibMgMatrixDesc_t descrA,
    int *array_d_IPIV[],
    void *array_d_B[],
    int IB,
    int JB,
    cudaLibMgMatrixDesc_t descrB,
    cudaDataType_t computeType,
    void *array_d_work[],
    int64_t lwork,
    int *info);
```

This function solves a linear system of multiple right-hand sides

\[ \text{op}(A)X = B \]

where \( A \) is a \( N \times N \) matrix, and was LU-factored by \textit{getrf}, that is, lower triangular part of \( A \) is \( L \), and upper triangular part (including diagonal elements) of \( A \) is \( U \). \( B \) is a \( N \times NRHS \) right-hand side matrix. The solution matrix \( X \) overwrites the right-hand-side matrix \( B \).

The input parameter \texttt{TRANS} is defined by

\[
\text{op}(A) = \begin{cases} 
A & \text{if TRANS} = \text{CUBLAS\_OP\_N} \\
A^T & \text{if TRANS} = \text{CUBLAS\_OP\_T} \\
A^H & \text{if TRANS} = \text{CUBLAS\_OP\_C}
\end{cases}
\]
The user has to provide device working space in `array_d_work`. `array_d_work` is a host pointer array of dimension $G$, where $G$ is number of devices. `array_d_work[j]` is a device pointer pointing to a device memory in $j$-th device. The data type of `array_d_work[j]` is `computeType`. The size of `array_d_work[j]` is `lwork` which is number of elements per device, returned by `cusolverMgGetrs_bufferSize()`.

If `array_d_IPIV` is null, no pivoting is performed. Otherwise, `array_d_IPIV` is an output of `getrf`. It contains pivot indices, which are used to permute right-hand sides.

If output parameter `info = -i` (less than zero), the $i$-th parameter is wrong (not counting handle).

The generic API has three different types, `dataTypeA` is data type of the matrix $A$, `dataTypeB` is data type of the matrix $B$, and `computeType` is compute type of the operation and data type of the workspace (`array_d_work`) `descrA` contains `dataTypeA`, so there is no explicit parameter of `dataTypeA`. `descrB` contains `dataTypeB`, so there is no explicit parameter of `dataTypeB`. `cusolverMgGetrs` only supports the following four combinations.

valid combination of data type and compute type

<table>
<thead>
<tr>
<th><code>DataTypeA</code></th>
<th><code>DataTypeB</code></th>
<th><code>ComputeType</code></th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUDA_R_32F</td>
<td>CUDA_R_32F</td>
<td>CUDA_R_32F</td>
<td>SGETRS</td>
</tr>

### Status Returned

| CUSOLVER_STATUS_SUCCESS       | the operation completed successfully. |
| CUSOLVER_STATUS_INVALID_VALUE | invalid parameters were passed (N<0 or NRHS<0). |
| CUSOLVER_STATUS_INTERNAL_ERROR | an internal operation failed. |

### 3.5. Dense Eigenvalue Solver Reference

This chapter describes eigenvalue solver API of cuSolverMG.
3.5.1. cusolverMgSyevd()

The helper functions below can calculate the sizes needed for pre-allocated buffer.

```c
 cusolverStatus_t
 cusolverMgSyevd_bufferSize(
     cusolverMgHandle_t handle,
     cusolverEigMode_t jobz,
     cublasFillMode_t uplo,
     int N,
     void *array_d_A[],
     int IA,
     int JA,
     cudaLibMgMatrixDesc_t descrA,
     void *W,
     cudaDataType_t dataTypeW,
     cudaDataType_t computeType,
     int64_t *lwork
 );
```

```c
 cusolverStatus_t
 cusolverMgSyevd(
     cusolverMgHandle_t handle,
     cusolverEigMode_t jobz,
     cublasFillMode_t uplo,
     int N,
     void *array_d_A[],
     int IA,
     int JA,
     cudaLibMgMatrixDesc_t descrA,
     void *W,
     cudaDataType_t dataTypeW,
     cudaDataType_t computeType,
     void *array_d_work[],
     int64_t lwork,
     int *info );
```

This function computes eigenvalues and eigenvectors of a symmetric (Hermitian) \( N \times N \) matrix \( A \). The standard symmetric eigenvalue problem is

\[
A^* V = V \Lambda
\]

where \( \Lambda \) is a real \( N \times N \) diagonal matrix. \( V \) is an \( N \times N \) unitary matrix. The diagonal elements of \( \Lambda \) are the eigenvalues of \( A \) in ascending order.

`cusolverMgSyevd` returns the eigenvalues in \( W \) and overwrites the eigenvectors in \( A \). \( W \) is a host \( 1 \times N \) vector.

The generic API has three different types, `dataTypeA` is data type of the matrix \( A \), `dataTypeW` is data type of the vector \( W \), and `computeType` is compute type of the operation and data type of the workspace \( \text{array}_d \text{work} \) \( \text{descrA} \) contains `dataTypeA`, so there is no explicit parameter of `dataTypeA`. `cusolverMgSyevd` only supports the following four combinations.

**valid combination of data type and compute type**

<table>
<thead>
<tr>
<th><code>dataTypeA</code></th>
<th><code>dataTypeW</code></th>
<th><code>computeType</code></th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUDA_R_32F</td>
<td>CUDA_R_32F</td>
<td>CUDA_R_32F</td>
<td>SSYEVD</td>
</tr>
<tr>
<td>CUDA_R_64F</td>
<td>CUDA_R_64F</td>
<td>CUDA_R_64F</td>
<td>DSYEVD</td>
</tr>
</tbody>
</table>
The user has to provide device working space in `array_d_work`. `array_d_work` is a host pointer array of dimension $G$, where $G$ is number of devices. `array_d_work[j]` is a device pointer pointing to a device memory in j-th device. The data type of `array_d_work[j]` is `computeType`. The size of `array_d_work[j]` is `lwork` which is number of elements per device, returned by `cusolverMgSyevd_bufferSize()`.

`array_d_A` is also a host pointer array of dimension $G`. `array_d_A[j]` is a device pointer pointing to a device memory in j-th device. The data type of `array_d_A[j]` is `dataTypeA`. The size of `array_d_A[j]` is about $N*TA*(blocks per device)$. The user has to prepare `array_d_A` manually (please check the samples in Appendix H).

If output parameter `info = -i` (less than zero), the i-th parameter is wrong (not counting handle). If `info = i` (greater than zero), i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

if `jobz = CUSOLVER_EIG_MODE_VECTOR`, $A$ contains the orthonormal eigenvectors of the matrix $A$. The eigenvectors are computed by a divide and conquer algorithm.

Remark 1: only `CUBLAS_FILL_MODE_LOWER` is supported, so the user has to prepare lower triangle of $A$.

Remark 2: only $IA=1$ and $JA=1$ are supported.

Remark 3: tile size $TA$ must be less or equal to 1024. To achieve best performance, $TA$ should be 256 or 512.

Appendix H provides three examples of `cusolverMgSyevd`.

**API of syevd**

A.1. cuSolverRF In-memory Example

This is an example in the C programming language of how to use the standard routines in the cuSolverRF library. We focus on solving the set of linear systems

\[ A_i x_i = f_i \]
but we change the indexing from one- to zero-based to follow the C programming language. The example begins with the usual includes and main()

```c
#include <stdio.h>
#include <stdlib.h>
#include <cuda_runtime.h>
#include "cusolverRf.h"

#define TEST_PASSED  0
#define TEST_FAILED  1

int main (void){
    /* matrix A */
    int n;
    int nnzA;
    int *Ap=NULL;
    int *Ai=NULL;
    double *Ax=NULL;
    int *d_Ap=NULL;
    int *d_Ai=NULL;
    double *d_rAx=NULL;
    /* matrices L and U */
    int nnzL, nnzU;
    int *Lp=NULL;
    int *Li=NULL;
    double* Lx=NULL;
    int *Up=NULL;
    int *Ui=NULL;
    double* Ux=NULL;
    /* reordering matrices */
    int *P=NULL;
    int *Q=NULL;
    int *d_P=NULL;
    int *d_Q=NULL;
    /* solution and rhs */
    int nrhs; // # of rhs for each system (currently only =1 is supported)
    double *d_X=NULL;
    double *d_T=NULL;
    cudaError_t cudaStatus;
    /* cuolverRf */
    cusolverRfHandle_t gH=NULL;
    cusolverStatus_t status;
    /* host sparse direct solver */
    /* ... */
    /* other variables */
    int tnnzL, tnnzU;
    int *tLp=NULL;
    int *tLi=NULL;
    double *tLx=NULL;
    int *tUp=NULL;
    int *tUi=NULL;
    double *tUx=NULL;
    double t1, t2;
```
Then we initialize the library.

```c
/* ASSUMPTION: recall that we are solving a set of linear systems
  A_{i} x_{i} = f_{i}  for i=0,...,k-1
  where the sparsity pattern of the coefficient matrices A_{i}
  as well as the reordering to minimize fill-in and the pivoting
  used during the LU factorization remain the same. */

/* Step 1: solve the first linear system (i=0) on the host,
   using host sparse direct solver, which involves
   full LU factorization and solve. */
/* ... */

/* Step 2: interface to the library by extracting the following
   information from the first solve:
   a) triangular factors L and U
   b) pivoting and reordering permutations P and Q
   c) also, allocate all the necessary memory */
/* ... */

/* Step 3: use the library to solve subsequent (i=1,...,k-1) linear systems
  a) the library setup (called only once) */
//create handle
status = cusolverRfCreate(&gH);
if (status != CUSOLVER_STATUS_SUCCESS){
    printf("[cusolverRf status %d]\n",status);
    return TEST_FAILED;
}

//set fast mode
status = cusolverRfSetResetValuesFastMode(gH,GLU_RESET_VALUES_FAST_MODE_ON);
if (status != CUSOLVER_STATUS_SUCCESS){
    printf("[cusolverRf status %d]\n",status);
    return TEST_FAILED;
}
```
Call refactorization and solve.

// assemble internal data structures (you should use the coefficient matrix A
// corresponding to the second (i=1) linear system in this call)
t1 = cusolver_test_seconds();
status = cusolverRfSetupHost(n, nnzA, Ap, Ai, Ax,
    nnzL, Lp, Li, Lx, nnzU, Up, Ui, Ux, P, Q, gH);
cudaStatus = cudaDeviceSynchronize();
t2 = cusolver_test_seconds();
if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
    printf ("[cusolverRf status \%d]\n",status);
    return TEST_FAILED;
}
printf("cusolverRfSetupHost time = \%f (s)\n", t2-t1);

// analyze available parallelism
T1 = cusolver_test_seconds();
status = cusolverRfAnalyze(gH);
cudaStatus = cudaDeviceSynchronize();
t2 = cusolver_test_seconds();
if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
    printf ("[cusolverRf status \%d]\n",status);
    return TEST_FAILED;
}
printf("cusolverRfAnalyze time = \%f (s)\n", t2-t1);

/* b) The library subsequent (i=1,...,k-1) LU re-factorization
and solve (called multiple times). */
for (i=1; i<k; i++){
    // LU re-factorization
    t1 = cusolver_test_seconds();
    status = cusolverRfRefactor(gH);
    cudaStatus = cudaDeviceSynchronize();
    t2 = cusolver_test_seconds();
    if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
        printf ("[cusolverRf status \%d]\n",status);
        return TEST_FAILED;
    }
    printf("cusolverRfRefactor time = \%f (s)\n", t2-t1);

    // forward and backward solve
    t1 = cusolver_test_seconds();
    status = cusolverRfSolve(gH, d_P, d_Q, nrhs, d_T, n, d_X, n);
    cudaStatus = cudaDeviceSynchronize();
    t2 = cusolver_test_seconds();
    if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
        printf ("[cusolverRf status \%d]\n",status);
        return TEST_FAILED;
    }
    printf("cusolverRfSolve time = \%f (s)\n", t2-t1);
Extract the results and return.

```c
// extract the factors (if needed)
status = cusolverRfExtractSplitFactorsHost(gH, &tnnzL, &tLp, &tLi, 
&tLx, &tnnzU, &tUp, &tUi, &tUx);
if(status != CUSOLVER_STATUS_SUCCESS){
    printf ("[cusolverRf status \%d\n",status);
    return TEST_FAILED;
}
/*
//print
int row, j;
printf("printing L\n");
for (row=0; row<n; row++){
    for (j=tLp[row]; j<tLp[row+1]; j++){
        printf("\%d,\%d,\%f\n",row,tLi[j],tLx[j]);
    }
}
printf("printing U\n");
for (row=0; row<n; row++){
    for (j=tUp[row]; j<tUp[row+1]; j++){
        printf("\%d,\%d,\%f\n",row,tUi[j],tUx[j]);
    }
}
*/
/* perform any other operations based on the solution */
/* ... */
/* check if done */
/* ... */
/* proceed to solve the next linear system */
/* update the coefficient matrix using reset values 
// (assuming that the new linear system, in other words, 
// new values are already on the GPU in the array d_rAx)
t1 = cusolver_test_seconds();
status = cusolverRfResetValues(n,nnzA,d_Ap,d_Ai,d_rAx,d_P,d_Q,gH);
cudaStatus = cudaDeviceSynchronize();
t2 = cusolver_test_seconds();
if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess))
{
    printf ("[cusolverRf status \%d\n",status);
    return TEST_FAILED;
}
printf("cusolverRfResetValues time = \%f (s)\n", t2-t1);
/* free memory and exit */
/* ... */
return TEST_PASSED;
```

A.2. cuSolverRF-batch Example

This chapter provides an example in the C programming language of how to use the batched routines in the cuSolverRF library. We focus on solving the set of linear systems

\[ A_i x_i = f_i \]
but we change the indexing from one- to zero-based to follow the C programming language. The first part is the usual includes and main definition

```c
#include <stdio.h>
#include <stdlib.h>
#include <cuda_runtime.h>
#include "cusolverRf.h"

#define TEST_PASSED  0
#define TEST_FAILED  1

int main (void){
    /* matrix A */
    int batchSize;
    int n;
    int nnzA;
    int *Ap=NULL;
    int *Ai=NULL;
    //array of pointers to the values of each matrix in the batch (of size
    //batchSize) on the host
    double **Ax_array=NULL;
    //For example, if Ax_batch is the array (of size batchSize*nnzA) containing
    //the values of each matrix in the batch written contiguosly one matrix
    //after another on the host, then Ax_array[j] = &Ax_batch[nnzA*j];
    //for j=0,...,batchSize-1.
    double *Ax_batch=NULL;
    int *d_Ap=NULL;
    int *d_Ai=NULL;
    //array of pointers to the values of each matrix in the batch (of size
    //batchSize) on the device
    double **d_Ax_array=NULL;
    //For example, if d_Ax_batch is the array (of size batchSize*nnzA)
    containing
    //the values of each matrix in the batch written contiguosly one matrix
    //after another on the device, then d_Ax_array[j] = &d_Ax_batch[nnzA*j];
    //for j=0,...,batchSize-1.
    double *d_Ax_batch=NULL;
    /* matrices L and U */
    int nnzL, nnzU;
    int *Lp=NULL;
    int *Li=NULL;
    double* Lx=NULL;
    int *Up=NULL;
    int *Ui=NULL;
    double* Ux=NULL;
    /* reordering matrices */
    int *P=NULL;
    int *Q=NULL;
    int *d_P=NULL;
    int *d_Q=NULL;
```
Next we initialize the data needed and the create library handles

```c
/* solution and rhs */
int nrhs; // # of rhs for each system (currently only = 1 is supported)
// temporary storage (of size 2 * batchSize * n * nrhs)
double *d_T = NULL;
// array (of size batchSize * n * nrhs) containing the values of each rhs in
// the batch written contiguously one rhs after another on the device
double **d_X_array = NULL;
// array (of size batchSize * n * nrhs) containing the values of each rhs in
// the batch written contiguously one rhs after another on the host
double **X_array = NULL;
/* cuda */
cudaError_t cudaStatus;
/* cusolverRf */
cusolverRfHandle_t gH = NULL;
cusolverStatus_t status;
/* host sparse direct solver */
...
/* other variables */
double t1, t2;

/* ASSUMPTION:
recall that we are solving a batch of linear systems
A_{j} x_{j} = f_{j} for j = 0, ..., batchSize-1
where the sparsity pattern of the coefficient matrices A_{j}
as well as the reordering to minimize fill-in and the pivoting
used during the LU factorization remain the same. */

/* Step 1: solve the first linear system (j = 0) on the host,
using host sparse direct solver, which involves
full LU factorization and solve. */
/* ... */

/* Step 2: interface to the library by extracting the following
information from the first solve:
a) triangular factors L and U
b) pivoting and reordering permutations P and Q
c) also, allocate all the necessary memory */
/* ... */

/* Step 3: use the library to solve the remaining (j = 1, ..., batchSize-1)
linear systems.
a) the library setup (called only once) */
// create handle
status = cusolverRfcreate(&gH);
if (status != CUSOLVER_STATUS_SUCCESS) {
    printf("[cusolverRf status %d]\n", status);
    return TEST_FAILED;
}
```
We call the batch solve method and return.

```c
    //assemble internal data structures
    t1 = cusolver_test_seconds();
    status = cusolverRfBatchSetupHost(batchSize, n, nnzA, Ap, Ai, Ax_array,
                                nnzL, Lp, Li, Lx, nnzU, Up, Ui, Ux, P, Q,
                                gH);
    cudaStatus = cudaDeviceSynchronize();
    t2 = cusolver_test_seconds();
    if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
        printf("[cusolverRf status %d]\n",status);
        return TEST_FAILED;
    }
    printf("cusolverRfBatchSetupHost time = %f (s)\n", t2-t1);

    //analyze available parallelism
    t1 = cusolver_test_seconds();
    status = cusolverRfBatchAnalyze(gH);
    cudaStatus = cudaDeviceSynchronize();
    t2 = cusolver_test_seconds();
    if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
        printf("[cusolverRf status %d]\n",status);
        return TEST_FAILED;
    }
    printf("cusolverRfBatchAnalyze time = %f (s)\n", t2-t1);

    /* b) The library subsequent (j=1,...,batchSize-1) LU re-factorization
        and solve (may be called multiple times). For the subsequent batches
        the values can be reset using cusolverRfBatch_reset_values_routine. */
    //LU re-factorization
    t1 = cusolver_test_seconds();
    status = cusolverRfBatchRefactor(gH);
    cudaStatus = cudaDeviceSynchronize();
    t2 = cusolver_test_seconds();
    if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
        printf("[cusolverRf status %d]\n",status);
        return TEST_FAILED;
    }
    printf("cusolverRfBatchRefactor time = %f (s)\n", t2-t1);

    //forward and backward solve
    t1 = cusolver_test_seconds();
    status = cusolverRfBatchSolve(gH, d_P, d_Q, nrhs, d_T, n, d_X_array, n);
    cudaStatus = cudaDeviceSynchronize();
    t2 = cusolver_test_seconds();
    if ((status != CUSOLVER_STATUS_SUCCESS) || (cudaStatus != cudaSuccess)) {
        printf("[cusolverRf status %d]\n",status);
        return TEST_FAILED;
    }
    printf("cusolverRfBatchSolve time = %f (s)\n", t2-t1);

    /* free memory and exit */
    /* ... */
    return TEST_PASSED;
```
Appendix B.
CSR QR BATCH EXAMPLES

B.1. Batched Sparse QR example 1

This chapter provides a simple example in the C programming language of how to use batched sparse QR to solve a set of linear systems

\[ A_i x_i = b_i \]

All matrices \(A_i\) are small perturbations of

\[
A = \begin{bmatrix}
1.0 & 0.0 & 0.0 & 0.0 \\
0.0 & 2.0 & 0.0 & 0.0 \\
0.0 & 0.0 & 3.0 & 0.0 \\
0.1 & 0.1 & 0.1 & 4.0
\end{bmatrix}
\]

All right-hand side vectors \(b_i\) are small perturbation of the Matlab vector 'ones(4,1)'.

We assume device memory is big enough to compute all matrices in one pass.
The usual includes and main definition

```c
#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cusolverSp.h>
#include <cuda_runtime_api.h>

int main(int argc, char* argv[]) {
    cusolverSpHandle_t cusolverH = NULL;
    // GPU does batch QR
    csrqrInfo_t info = NULL;
    cusparseMatDescr_t descrA = NULL;
    cusparseStatus_t cusparse_status = CUSPARSE_STATUS_SUCCESS;
    cusolverStatus_t cusolver_status = CUSOLVER_STATUS_SUCCESS;
    cudaError_t cudaStat1 = cudaSuccess;
    cudaError_t cudaStat2 = cudaSuccess;
    cudaError_t cudaStat3 = cudaSuccess;
    cudaError_t cudaStat4 = cudaSuccess;
    cudaError_t cudaStat5 = cudaSuccess;

    // GPU does batch QR
    // d_A is CSR format, d_csrValA is of size nnzA*batchSize

```
C.1. QR Factorization Dense Linear Solver

This chapter provides a simple example in the C programming language of how to use a dense QR factorization to solve a linear system

\[ Ax = b \]

A is a 3x3 dense matrix, nonsingular.

\[
A = \begin{pmatrix}
1.0 & 2.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
2.0 & 1.0 & 1.0
\end{pmatrix}
\]

The following code uses three steps:

Step 1: A = Q*R by geqrf.

Step 2: B := Q^T*B by ormqr.

Step 3: solve R*X = B by trsm.
/*  * How to compile (assume cuda is installed at /usr/local/cuda/)  * nvcc -c -I/usr/local/cuda/include ormqr_example.cpp  * nvcc -o -fopenmp a.out ormqr_example.o -L/usr/local/cuda/lib64 -lcudart -lcublas -lcusolver  * */

#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cublas_v2.h>
#include <cusolverDn.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++)
    {
        for(int col = 0 ; col < n ; col++)
        {
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f
", name, row+1, col+1, Areg);
        }
    }
}

int main(int argc, char*argv[])
{
    cusolverDnHandle_t cusolverH = NULL;
    cublasHandle_t cublasH = NULL;
    cublasStatus_t cublas_status = CUBLAS_STATUS_SUCCESS;
    cusolverStatus_t cusolver_status = CUSOLVER_STATUS_SUCCESS;

C.2. orthogonalization

This chapter provides a simple example in the C programming language of how to do orthogonalization by QR factorization.

\[ A = QR \]

A is a 3x2 dense matrix,

\[
A = \begin{pmatrix} 
1.0 & 2.0 \\
4.0 & 5.0 \\
2.0 & 1.0 \\
\end{pmatrix}
\]

The following code uses three steps:
Step 1: A = QR by geqrf.
Step 2: form Q by orgqr.
Step 3: check if Q is unitary or not.
The usual includes and main definition

```c
/*
 * How to compile (assume cuda is installed at /usr/local/cuda/)
 *   nvcc -c -I/usr/local/cuda/include orgqr_example.cpp
 *   g++ -fopenmp -o a.out orgqr_example.o -L/usr/local/cuda/lib64 -lcudart -lcublas -lcusolver
 */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cublas_v2.h>
#include <cusolverDn.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++){
        for(int col = 0 ; col < n ; col++){
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f\n", name, row+1, col+1, Areg);
        }
    }
}

int main(int argc, char*argv[]) {
    cusolverDnHandle_t cusolverH = NULL;
    cublasHandle_t cublasH = NULL;
    cublasStatus_t cublas_status = CUBLAS_STATUS_SUCCESS;
    cusolverStatus_t cusolver_status = CUSOLVER_STATUS_SUCCESS;
    cudaError_t cudaStat1 = cudaSuccess;
    cudaError_t cudaStat2 = cudaSuccess;
    cudaError_t cudaStat3 = cudaSuccess;
    cudaError_t cudaStat4 = cudaSuccess;
    const int m = 3;
    const int n = 2;
    const int lda = m;
    /*
     *   | 1 2 |
     *   A = | 4 5 |
     *    | 2 1 |
     */
```
Create the library handle and load the data

```c
double A[lda*n] = { 1.0, 4.0, 2.0, 2.0, 5.0, 1.0};
double Q[lda*n]; // orthonormal columns
double R[n*n]; // R = I - Q**T*Q

double *d_A = NULL;
double *d_tau = NULL;
int *devInfo = NULL;
double *d_work = NULL;

double *d_R = NULL;

int lwork_geqrf = 0;
int lwork_orgqr = 0;
int lwork = 0;

int info_gpu = 0;

const double h_one = 1;
const double h_minus_one = -1;

printf("A = (matlab base-1)\n");
printMatrix(m, n, A, lda, "A");
printf("====\n");

// step 1: create cusolverDn/cublas handle

cusolver_status = cusolverDnCreate(&cusolverH);
assert(CUSOLVER_STATUS_SUCCESS == cusolver_status);
cublas_status = cublasCreate(&cublasH);
assert(CUBLAS_STATUS_SUCCESS == cublas_status);

// step 2: copy A and B to device

cudaStat1 = cudaMalloc ((void**)&d_A , sizeof(double)*lda*n);
cudaStat2 = cudaMalloc ((void**)&d_tau, sizeof(double)*n);
cudaStat3 = cudaMalloc ((void**)&devInfo, sizeof(int));
cudaStat4 = cudaMalloc ((void**)&d_R  , sizeof(double)*n*n);
assert(cudaSuccess == cudaStat1);
assert(cudaSuccess == cudaStat2);
assert(cudaSuccess == cudaStat3);
assert(cudaSuccess == cudaStat4);

cudaStat1 = cudaMemcpy(d_A, A, sizeof(double)*lda*n,
cudaMemcpyHostToDevice);
assert(cudaSuccess == cudaStat1);
```
Call the solver

```c
// step 3: query working space of geqrf and orgqr
    cusolver_status = cusolverDnDgeqrf_bufferSize(
        cusolverH,
        m, n, d_A, lda,
        &lwork_geqrf);
    assert (cusolver_status == CUSOLVER_STATUS_SUCCESS);
    cusolver_status = cusolverDnDorgqr_bufferSize(

    if (cublasH) cblasDestroy(cublasH);
    if (cusolverH) cusolverDnDestroy(cusolverH);

cudaDeviceReset();
return 0;
```
D.1. LU Factorization

This chapter provides a simple example in the C programming language of how to use a dense LU factorization to solve a linear system

\[ Ax = b \]

A is a 3x3 dense matrix, nonsingular.

\[
A = \begin{pmatrix}
1.0 & 2.0 & 3.0 \\
4.0 & 5.0 & 6.0 \\
7.0 & 8.0 & 10.0
\end{pmatrix}
\]

The code uses getrf to do LU factorization and getsr to do backward and forward solve. The parameter pivot_on decides whether partial pivoting is performed or not.
/* How to compile (assume cuda is installed at /usr/local/cuda/)
   nvcc -c -I/usr/local/cuda/include getrf_example.cpp
   g++ -fopenmp -o a.out getrf_example.o -L/usr/local/cuda/lib64 -lcusolver -lcudart */

#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cusolverDn.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++){
        for(int col = 0 ; col < n ; col++){
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f\n", name, row+1, col+1, Areg);
        }
    }
}

Appendix E.
CHOLESKY EXAMPLES

E.1. batched Cholesky Factorization

This chapter provides a simple example in the C programming language of how to use a
batched dense Cholesky factorization to solve a sequence of linear systems

\[ A[i]x[i] = b[i] \]

each \( A[i] \) is a 3x3 dense Hermitian matrix. In this example, there are two matrices, \( A_0 \)
and \( A_1 \). \( A_0 \) is positive definite and \( A_1 \) is not.

The code uses `potrfBatched` to do Cholesky factorization and `potrsBatched` to do
backward and forward solve. `potrfBatched` would report singularity on \( A_1 \).
How to compile (assume cuda is installed at /usr/local/cuda/)
   nvcc -c -I/usr/local/cuda/include batchchol_example.cpp
   g++ -o a.out batchchol_example.o -L/usr/local/cuda/lib64 -lcusolver -lcudart
*/
#include <stdio.h>

EXAMPLES OF DENSE EIGENVALUE SOLVER

F.1. Standard Symmetric Dense Eigenvalue Solver

This chapter provides a simple example in the C programming language of how to use syevd to compute the spectrum of a dense symmetric system by

\[ Ax = \lambda x \]

where \( A \) is a 3x3 dense symmetric matrix

\[
A = \begin{pmatrix}
3.5 & 0.5 & 0 \\
0.5 & 3.5 & 0 \\
0 & 0 & 2
\end{pmatrix}
\]
The following code uses \texttt{syevd} to compute eigenvalues and eigenvectors, then compare to exact eigenvalues \{2,3,4\}.

```c
#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cusolverDn.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++){
        for(int col = 0 ; col < n ; col++){
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f\n", name, row+1, col+1, Areg);
        }
    }
}

int main(int argc, char*argv[])
{
    cusolverDnHandle_t cusolverH = NULL;
    cusolverStatus_t cusolver_status = CUSOLVER_STATUS_SUCCESS;
    cudaError_t cudaStat1 = cudaSuccess;
    cudaError_t cudaStat2 = cudaSuccess;
    cudaError_t cudaStat3 = cudaSuccess;
    const int m = 3;
    const int lda = m;
    double A[lda*m] = { 3.5, 0.5, 0, 0.5, 3.5, 0, 0, 0, 2.0};
    double lambda[m] = { 2.0, 3.0, 4.0};
    double V[lda*m]; // eigenvectors
    double W[m]; // eigenvalues
    double *d_A = NULL;
    double *d_W = NULL;
    int *devInfo = NULL;
    double *d_work = NULL;
    int lwork = 0;
    int info_gpu = 0;

    printf("A = (matlab base-1)\n");
    printMatrix(m, m, A, lda, "A");
    printf("=====
");
```
call eigenvalue solver

// step 1: create cusolver/cublas handle
    cusolver_status = cusolverDnCreate(&cusolverH);
    assert(CUSOLVER_STATUS_SUCCESS == cusolver_status);

// step 2: copy A and B to device
    cudaStat1 = cudaMalloc ((void**)&d_A, sizeof(double) * lda * m);

F.4. Generalized Symmetric-Definite Dense Eigenvalue Solver

This chapter provides a simple example in the C programming language of how to use sygvd to compute spectrum of a pair of dense symmetric matrices \((A, B)\) by

\[
Ax = \lambda Bx
\]

where \(A\) is a 3x3 dense symmetric matrix

\[
A = \begin{pmatrix}
3.5 & 0.5 & 0 \\
0.5 & 3.5 & 0 \\
0 & 0 & 2
\end{pmatrix}
\]
and $B$ is a 3x3 positive definite matrix

\[
B = \begin{bmatrix}
10 & 2 & 3 \\
2 & 10 & 5 \\
3 & 5 & 10
\end{bmatrix}
\]
The following code uses \texttt{sygvd} to compute eigenvalues and eigenvectors, then compare to exact eigenvalues \{0.158660256604, 0.370751508101882, 0.6\}.

```c
#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cusolverDn.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++)
    {
        for(int col = 0 ; col < n ; col++)
        {
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f\n", name, row+1, col+1, Areg);
        }
    }
}

int main(int argc, char*argv[])

F.5. Standard Symmetric Dense Eigenvalue Solver (via Jacobi method)

This chapter provides a simple example in the C programming language of how to use `syevj` to compute the spectrum of a dense symmetric system by

\[ Ax = \lambda x \]

where `A` is a 3x3 dense symmetric matrix

\[
A = \begin{pmatrix}
3.5 & 0.5 & 0 \\
0.5 & 3.5 & 0 \\
0 & 0 & 2
\end{pmatrix}
\]
The following code uses `syevj` to compute eigenvalues and eigenvectors, then compare to exact eigenvalues [2,3,4].

```c
#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cusolverDn.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++){
        for(int col = 0 ; col < n ; col++){
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f\n", name, row+1, col+1, Areg);
        }
    }
}

int main(int argc, char*argv[])
{
    cusolverDnHandle_t cusolverH = NULL;
    cudaStream_t stream = NULL;
    syevjInfo_t syevj_params = NULL;
    cusolverStatus_t status = CUSOLVER_STATUS_SUCCESS;
    cudaError_t cudaStat1 = cudaSuccess;
    cudaError_t cudaStat2 = cudaSuccess;
    cudaError_t cudaStat3 = cudaSuccess;
    const int m = 3;
    const int lda = m;
    double A[lda*m] = { 3.5, 0.5, 0, 0.5, 3.5, 0, 0, 0, 2.0};
    double lambda[m] = { 2.0, 3.0, 4.0};
    double V[lda*m]; /* eigenvectors */
    double W[m]; /* eigenvalues */
    double *d_A = NULL; /* device copy of A */
    double *d_W = NULL; /* eigenvalues */
    int *d_info = NULL; /* error info */
    int lwork = 0; /* size of workspace */
    double *d_work = NULL; /* device workspace for syevj */
    int info = 0; /* host copy of error info */

    /* configuration of syevj */
    const double tol = 1.e-7;
    const int max_sweeps = 15;
    const cusolverEigMode_t jobz = CUSOLVER_EIG_MODE_VECTOR; // compute eigenvectors.
    const cublasFillMode_t uplo = CUBLAS_FILL_MODE_LOWER;
```

configure parameters of syevj

```c
/* numerical results of syevj */
double residual = 0;
int executed_sweeps = 0;

printf("example of syevj \n");

        d_W,  
        &lwork,
        syevj_params);
    assert(CUSOLVER_STATUS_SUCCESS == status);

    cudaStat1 = cudaMalloc((void**)&d_work, sizeof(double)*lwork);
    assert(cudaSuccess == cudaStat1);

/* step 5: compute eigen-pair */
    status = cusolverDnDsyevj(
        cusolverH,
        jobz,  
        uplo,  
        m,    
        d_A,  
        lda,  
        d_W,  
        d_W,  
        lwork,  
        d_info,  
        syevj_params);
    cudaStat1 = cudaDeviceSynchronize();
    assert(CUSOLVER_STATUS_SUCCESS == status);
    assert(cudaSuccess == cudaStat1);

    cudaStat1 = cudaMemcpy(W, d_W, sizeof(double)*m, cudaMemcpyDeviceToHost);
    cudaStat2 = cudaMemcpy(V, d_A, sizeof(double)*lda*m, cudaMemcpyDeviceToHost);
    cudaStat3 = cudaMemcpy(&info, d_info, sizeof(int), cudaMemcpyDeviceToHost);
    assert(cudaSuccess == cudaStat1);
    assert(cudaSuccess == cudaStat2);
    assert(cudaSuccess == cudaStat3);

    if ( 0 == info ){
        printf("syevj converges \n");
    }else if ( 0 > info ){  
        printf("%d-th parameter is wrong \n", -info);
        exit(1);
    }else{
        printf("WARNING: info = %d : syevj does not converge \n", info );
    }

    printf("Eigenvalue = (matlab base-1), ascending order\n");
    for(int i = 0 ; i < m ; i++){
        printf("W[%d] = %.E\n", i+1, W[i]);
    }

    printf("V = (matlab base-1)\n");
    printMatrix(m, m, V, lda, "V");
    printf("=====\n");
```

This chapter provides a simple example in the C programming language of how to use sygvj to compute spectrum of a pair of dense symmetric matrices (A,B) by

\[ Ax = \lambda Bx \]

where A is a 3x3 dense symmetric matrix

\[
A = \begin{bmatrix}
3.5 & 0.5 & 0 \\
0.5 & 3.5 & 0 \\
0 & 0 & 2
\end{bmatrix}
\]

and B is a 3x3 positive definite matrix

check the result

```c
/* step 6: check eigenvalues */
double lambda_sup = 0;
for(int i = 0 ; i < m ; i++)
    double error = fabs( lambda[i] - W[i]);
    lambda_sup = (lambda_sup > error)? lambda_sup : error;
printf("|lambda - W| = %E\n", lambda_sup);

status = cusolverDnXsyevjGetSweeps(
cusolverH,
syevj_params,
&executed_sweeps);
assert(CUSOLVER_STATUS_SUCCESS == status);

status = cusolverDnXsyevjGetResidual(
cusolverH,
syevj_params,
&residual);
assert(CUSOLVER_STATUS_SUCCESS == status);

printf("residual |A - V*W*V**H|_F = %E \n", residual );
printf("number of executed sweeps = %d \n", executed_sweeps );

/* free resources */

F.7. batch eigenvalue solver for dense symmetric matrix

This chapter provides a simple example in the C programming language of how to use syevjBatched to compute the spectrum of a sequence of dense symmetric matrices by

\[ A_j x = \lambda x \]

where \( A_0 \) and \( A_1 \) are 3x3 dense symmetric matrices

\[
A_0 = \begin{pmatrix}
1 & -1 & 0 \\
-1 & 2 & 0 \\
0 & 0 & 0
\end{pmatrix}
\]

\[
A_1 = \begin{pmatrix}
3 & 4 & 0 \\
4 & 7 & 0 \\
0 & 0 & 0
\end{pmatrix}
\]

The following code uses \texttt{syevjBatched} to compute eigenvalues and eigenvectors

\[ A_j = V_j^* W_j^* V_j^T \]
The user can disable/enable sorting by the function \texttt{cusolverDnXsyevjSetSortEig}.

```c
#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>

void printMatrix(int m, int n, const double*A, int lda, const char* name)
{
    for(int row = 0 ; row < m ; row++){
        for(int col = 0 ; col < n ; col++){
            double Areg = A[row + col*lda];
            printf("%s(%d,%d) = %f\n", name, row+1, col+1, Areg);
        }
    }
}

int main(int argc, char*argv[])
{

G.3. batch dense SVD solver

This chapter provides a simple example in the C programming language of how to use \texttt{gesvdjBatched} to compute the SVD of a sequence of dense matrices

\[ A_j = U_j \Sigma_j V_j^H \]

where \( A_0 \) and \( A_1 \) are 3x2 dense matrices

\[
A_0 = \begin{pmatrix}
1 & -1 \\
-1 & 2 \\
0 & 0
\end{pmatrix}
\]

\[
A_1 = \begin{pmatrix}
3 & 4 \\
4 & 7 \\
0 & 0
\end{pmatrix}
\]

The following code uses \texttt{gesvdjBatched} to compute singular values and singular vectors.
The user can disable/enable sorting by the function \texttt{cusolverDnXgesvdjSetSortEig}.

```c
/*
 * How to compile (assume cuda is installed at /usr/local/cuda/)
 *   nvcc -c -I/usr/local/cuda/include gesvdjbatch_example.cpp
 *   g++ -o gesvdjbatch_example gesvdjbatch_example.o -L/usr/local/cuda/lib64 -lcusolver -lcudart
 */
#include <stdio.h>
#include <stdlib.h>
#include <assert.h>
#include <cuda_runtime.h>
#include <cusolverDn.h>

G.4. SVD approximation

This chapter provides a simple example in the C programming language of how to approximate singular value decomposition by `gesvdaStridedBatched`.

\[ A = U \Sigma V^H \]

A0 and A1 are a 3x2 dense matrices,

A0 = \[
\begin{pmatrix}
1.0 & 2.0 \\
4.0 & 5.0 \\
2.0 & 1.0 \\
\end{pmatrix}
\]

A1 = \[
\begin{pmatrix}
10.0 & 9.0 \\
8.0 & 7.0 \\
6.0 & 5.0 \\
\end{pmatrix}
\]
Examples of Singular Value Decomposition

### G.5. 64-bit GESVD

This chapter provides a simple example in the C programming language of how to use cusolverDnGesvd.

\[
A = U \Sigma V^H
\]
A is a 3x2 dense matrix,

\[ A = \begin{pmatrix} 1.0 & 2.0 \\ 4.0 & 5.0 \\ 2.0 & 1.0 \end{pmatrix} \]

The following code uses three steps:

Step 1: compute \( A = U^*S^*V^T \)

Step 2: check accuracy of singular value

Step 3: measure residual \( A - U^*S^*V^T \)
Examples of Singular Value Decomposition

/*
   * How to compile (assume cuda is installed at /usr/local/cuda/)
   * nvcc -c -I/usr/local/cuda/include svd64_example.cpp

Appendix H. EXAMPLES OF MULTIGPU EIGENVALUE SOLVER

This chapter provides three examples to perform multiGPU symmetric eigenvalue solver. The difference among them is how to generate the testing matrix. The testing matrix is a tridiagonal matrix, from standard 3-point stencil of Laplacian operator with Dirichlet boundary condition, so each row has (-1, 2, -1) signature.

The spectrum has analytic formula, we can check the accuracy of eigenvalues easily. The user can change the dimension of the matrix to measure the performance of eigenvalue solver.

The example code enables peer-to-peer access to take advantage of NVLINK. The user can check the performance by on/off peer-to-peer access.

The procedures of these three examples are 1) to prepare a tridiagonal matrix in distributed sense, 2) to query size of the workspace and to allocate the workspace for each device, 3) to compute eigenvalues and eigenvectors, and 4) to check accuracy of eigenvalues.

The example 1 allocates distributed matrix by calling `createMat`. It generates the matrix on host memory and copies it to distributed device memory via `memcpyH2D`.

The example 2 allocates distributed matrix manually, generates the matrix on host memory and copies it to distributed device memory manually. This example is for the users who are familiar with data layout of ScaLAPACK.

The example 3 allocates distributed matrix by calling `createMat` and generates the matrix element-by-element on distributed matrix via `memcpyH2D`. The user needs not to know the data layout of ScaLAPACK. It is useful when the matrix is sparse.

Appendix I.
EXAMPLES OF MULTIGPU LINEAR SOLVER

This chapter provides examples to perform multiGPU linear solver.

The example code enables peer-to-peer access to take advantage of NVLINK. The user can check the performance by on/off peer-to-peer access.

The example 1 solves linear system by LU with partial pivoting (getrf and getrs). It allocates distributed matrix by calling createMat. Then generates the matrix on host memory and copies it to distributed device memory via memcpyH2D.

The example 1 solves linear system by Cholesky factorization (potrf and potrs). It allocates distributed matrix by calling createMat. Then generates the matrix on host memory and copies it to distributed device memory via memcpyH2D.

The example 1 solves linear system using the inverse of an Hermitian positive definite matrix using (potrf and potri). It allocates distributed matrix by calling createMat. Then generates the matrix on host memory and copies it to distributed device memory via memcpyH2D.
I.1. GETRF and GETRS of 1D Laplacian operator (example 1)
