Chapter 1. Introduction

This document introduces CUDA-GDB, the NVIDIA® CUDA® debugger for Linux and QNX targets.

1.1. What is CUDA-GDB?

CUDA-GDB is the NVIDIA tool for debugging CUDA applications running on Linux and QNX. CUDA-GDB is an extension to GDB, the GNU Project debugger. The tool provides developers with a mechanism for debugging CUDA applications running on actual hardware. This enables developers to debug applications without the potential variations introduced by simulation and emulation environments.

1.2. Supported Features

CUDA-GDB is designed to present the user with a seamless debugging environment that allows simultaneous debugging of both GPU and CPU code within the same application. Just as programming in CUDA C is an extension to C programming, debugging with CUDA-GDB is a natural extension to debugging with GDB. The existing GDB debugging features are inherently present for debugging the host code, and additional features have been provided to support debugging CUDA device code.

CUDA-GDB supports debugging C/C++ and Fortran CUDA applications. Fortran debugging support is limited to 64-bit Linux operating system.

CUDA-GDB allows the user to set breakpoints, to single-step CUDA applications, and also to inspect and modify the memory and variables of any given thread running on the hardware.

CUDA-GDB supports debugging all CUDA applications, whether they use the CUDA driver API, the CUDA runtime API, or both.

CUDA-GDB supports debugging kernels that have been compiled for specific CUDA architectures, such as sm_75 or sm_80, but also supports debugging kernels compiled at runtime, referred to as just-in-time compilation, or JIT compilation for short.
1.3. About This Document

This document is the main documentation for CUDA-GDB and is organized more as a user manual than a reference manual. The rest of the document will describe how to install and use CUDA-GDB to debug CUDA kernels and how to use the new CUDA commands that have been added to GDB. Some walk-through examples are also provided. It is assumed that the user already knows the basic GDB commands used to debug host applications.
Chapter 2. Release Notes

12.0 Release

Updated GDB version

Moving from GDB 10.2 to 12.1

See GDB 12.1 changes

Texture and surface reference support removed

CTK 12.0 removed support for the Texture and Surface Reference API. Support for printing texture and surface references has been removed.

CUDA Memory Checker integration removed

cuda-memcheck has been deprecated in CUDA 11.x and replaced by Compute Sanitizer. The new memory checking workflow is to use Compute Sanitizer from the CLI. This will support coredumps when issues are detected which can then be opened and inspected with cuda-gdb, similar to other coredumps. Support for cuda-memcheck has been removed with the CUDA 12.0 release.

Debugging of applications using CUDA Dynamic Parallelism

Support for debugging applications using CUDA Dynamic Parallelism with the classic debugger backend or on Maxwell GPUs has been removed by default for applications compiled with the CTK 12.0 or newer. Debugging can be accomplished in these situations by recompiling the application while passing the -DCUDA_FORCE_CDP1_IF_SUPPORTED flag.

Features

- Move from base gdb/10.2 to gdb/12.1.
- Add initial support for Thread Block Clusters.
- Change default behavior of --cuda-use-lockfile to 0. Lockfiles are no longer created by default.

Bugfixes

- Address a hang that could be encountered when stepping through device system calls.
- Fix an overflow issue with displaying active warp masks in info cuda commands.
- Change internal CUDA Dynamic Parallelism detection breakpoint to be set only when `break_on_launch` is enabled.
- Remove unsupported `gpu_busy_check` setting.

### 11.8 Release

**Features**

- Use the new Unified Debugger (UD) debugging backend by default.
- Add support for debugging applications using CUDA Lazy Loading.
- Debugger is now enabled on Windows Subsystem for Linux (WSL).
- Add basic type support for printing FP8 values (E4M3 and E5M2).

**Notes**

- By default, cuda-gdb will use the new Unified Debugger (UD) backend. This change is transparent to most users using Pascal or newer cards. For Maxwell debugging, or to force the old classic debugging backend, set `CUDBG_USE_LEGACY_DEBUGGER` to 1 in your environment.
- When using debugger features on WSL, it’s recommended to disable Timeout Detection and Recovery (TDR) on the host.
- WSL is not supported on GH100 platforms with this release.

### 11.7 Release

**Features**

- Major `break_on_launch` performance enhancements to use new `KERNEL_READY` notification mechanism instead of setting manual breakpoints.
- Refactor info cuda command output to be more condensed. Omit outputting inactive messages.
- Added new `--disable-python` commandline option to disable Python interpreter dlopen.

**Bugfixes**

- Fix for follow-fork child to avoid hanging behavior when both parent and child processes use CUDA.
- Added a missing `dlsym` of a `libpython` function that was causing errors with some versions of `libpython`. 
11.6 Release

**Updated GDB version**

Moving from GDB 10.1 to 10.2

[See GDB 10.2 changes](#)

**Features**

- Add erorpc instruction prefix to the disassembly view. If an error PC is set, prefix the instruction with `*>

**Bugfixes**

- Fix lineinfo frames to properly display the source filename.
- Fix to allow writing to gpu global memory that was allocated from the host.
- Fix a bug that was preventing reading host variables during certain situations.
- Fix a cuda-gdbserver init check that prevented QNX from starting.

11.5 Release

**Python 3 support on Jetson and Drive Tegra devices**

Support for Python 2 has been removed. CUDA-GDB now supports Python 3 on Jetson and Drive Tegra devices.

**Bugfixes**

- Added robust version checks when dynamic loading the libpython3 library. The loaded libpython3 will match the version of the python3 runtime in PATH.
- Added support for checking PEP-3149 flag names when loading libpython3 libraries.
- Added support for dynamic loading of Python 3.9.
- Fix to avoid overriding PYTHONPATH on certain RHEL distributions.

11.4 Update 1 Release

**Known Issues with Fedora 34**

CUDA-GDB has known issues with debugging on Fedora 34 and may not be reliable.

**Bugfixes**

- Enabled python integration for ppc64le and aarch64 SBSA.
- Fixed a performance regression when debugging CUDA apps.
- Fixed an intermitent hang with remote debugging via cuda-gdbserver.
- Fixed bug with set cuda api_failures stop not triggering breakpoints on failure.
Changed python behavior to dlopen libpython libraries that match the version of the python3 interpreter in PATH.

OpenMP Fortran: Fixed a crash when setting breakpoints inside an OpenMP parallel region.

OpenMP: Better support for printing local variables within a parallel region.

Fortran: Added updated support for printing assumed shape arrays and array slices.

Fixed selecting between host and device thread focus in cudacore debugging.

Various fixes for QNX remote debugging.

11.4 Release

Updated GDB version

Moving from GDB 8.3 to 10 (based on GDB 10.1)

See GDB 10.1 changes

Python 3 support

Support for Python 2 has been removed. CUDA-GDB now supports Python 3.

GDB TUI mode disabled

Support for GDB TUI mode has been disabled. This avoids cross platform dependency mismatches for OSes that lack ncurses-5.5 support.

Kepler deprecation notice

Support for Kepler devices (sm_35 and sm_37) is deprecated. Kepler support will be dropped in an upcoming release.

Coredump support

Add support for writing coredumps to named pipe using CUDA_COREDUMP_FILE.

Bugfixes

Add support for displaying SIGTRAP exception in coredumps.

Disabled ability to enable scheduler-locking when debugging CUDA targets.

Fix for cuda_register_name and cuda_special_register_name to avoid returning old cached result on error.

Fix intermitent race condition when creating the CUDA temporary directory.

Various fixes for QNX remote debugging.
11.3 Release

Python 2 deprecation notice

Support for Python 2 is being deprecated. CUDA-GDB will move to build with Python 3 support in an upcoming release.

Bugfixes

‣ Improvements to late attach for remote debugging.

11.2 Update 1 Release

GDB TUI deprecation notice

Support for GDB TUI mode is being deprecated. This will avoid cross platform dependency mismatches for OSes that lack ncurses-5.5 support. GDB TUI mode will be disabled in an upcoming release.

Bugfixes

‣ Fixed printing of strings in the global GPU memory while running CPU code.
‣ Fixed a bug with extended debug_line handling.
‣ Fixed truncation with builtin gdb variables such as gridDim.
‣ Fixed a segfault during startup for DWARF dies missing names.
‣ Fixed a segfault when a CUDA kernel calls assert.
‣ Fixed a bug that prevented debugging cubins > 2GB.
‣ Added minor usability enhancements for cubins compiled with --lineinfo.
‣ Fixed a segfault cause by a pretty printer when using CUDA-GDB within CLion.

11.1 Release

Updated GDB version

Moving from GDB 8.2 to 8.3 (based on gdb 8.3.1).

See gdb 8.3.1 changes

Support for SM 8.6

CUDA-GDB now supports Devices with Compute Capability 8.6.

Updated DWARF parser

Old binaries might need to be recompiled in order to ensure CUDA-specific DWARF info are up to date.

Bugfixes

‣ Fixed an intermittent deadlock when attaching to a running CUDA process.
Fixed a bug when inspecting the value of half registers.

11.0 Release

Updated GDB version

CUDA-GDB has been upgraded from GDB/7.12 to GDB/8.2.

Support for SM8.0

CUDA-GDB now supports Devices with Compute Capability 8.0.

Support for Bfloat16

Support for Bfloat16 (__nv_bfloat16) types have been added.

MIG support

CUDA-GDB supports MIG. There can be a separate debugger session on each MIG instance. Refer to Multiple Debuggers in case multiple debuggers are needed.

Mac support

Debugging on MacOS is no longer supported. However, MacOS can still be used as the host system (where CUDA-GDB runs under MacOS, using cuda-gdbserver to debug a remote target). The download for the MacOS version of cuda-gdb can be found at the following location: Download Here

10.1 Release

Enhanced debugging with only linenumber information

Several enhancements were made to cuda-gdb’s support for debugging programs compiled with -lineinfo but not with -G. This is intended primarily for debugging programs built with OptiX/RTCore.

See also Compilation With Linenumber Information

10.0 Release

Turing Uniform Register Support

Support added to cuda-gdb for examining and modifying uniform registers on Turing GPUs.

9.2 Release

User induced core dump support

For the devices that support compute preemption, user induced core dump support is added. New environment variable: CUDA_ENABLE_USER_TRIGGERED_COREDUMP can be used to enable this feature.

9.1 Release

Volta-MPS core dump support

GPU core dump generation is supported on Volta-MPS.
Lightweight GPU core dump support

CUDA-GDB supports reading lightweight GPU core dump files. New environment variable: CUDA_ENABLE_LIGHTWEIGHT_COREDUMP can be used to enable this feature.

7.0 Release

GPU core dump support

CUDA-GDB supports reading GPU and GPU+CPU core dump files. New environment variables: CUDA_ENABLE_COREDUMP_ON_EXCEPTION, CUDA_ENABLE_CPU_COREDUMP_ON_EXCEPTION and CUDA_COREDUMP_FILE can be used to enable and configure this feature.

6.5 Release

CUDA Fortran Support

CUDA-GDB supports CUDA Fortran debugging on 64-bit Linux operating systems.

GDB 7.6.2 Code Base

The code base for CUDA-GDB was upgraded to GDB 7.6.2.

6.0 Release

Unified Memory Support

Managed variables can be read and written from either a host thread or a device thread. The debugger also annotates memory addresses that reside in managed memory with @managed. The list of statically allocated managed variables can be accessed through a new info cuda managed command.

GDB 7.6 Code Base

The code base for CUDA-GDB was upgraded from GDB 7.2 to GDB 7.6.

Android Support

CUDA-GDB can now be used to debug Android native applications either locally or remotely.

Single-Stepping Optimizations

CUDA-GDB can now use optimized methods to single-step the program, which accelerate single-stepping most of the time. This feature can be disabled by issuing set cuda single_stepping_optimizations off.

Faster Remote Debugging

A lot of effort has gone into making remote debugging considerably faster, up to 2 orders of magnitude. The effort also made local debugging faster.

Kernel Entry Breakpoints

The set cuda break_on_launch option will now break on kernels launched from the GPU. Also, enabling this option does not affect kernel launch notifications.
**Precise Error Attribution**

On Maxwell architecture (SM 5.0), the instruction that triggers an exception will be reported accurately. The application keeps making forward progress and the PC at which the debugger stops may not match that address but an extra output message identifies the origin of the exception.

**Live Range Optimizations**

To mitigate the issue of variables not being accessible at some code addresses, the debugger offers two new options. With `set cuda value_extrapolation`, the latest known value is displayed with (possibly) prefix. With `set cuda ptx_cache`, the latest known value of the PTX register associated with a source variable is displayed with the (cached) prefix.

**Event Notifications**

Kernel event notifications are not displayed by default any more.

New kernel events verbosity options have been added: `set cuda kernel_events`, `set cuda kernel_events_depth`. Also `set cuda defer_kernel_launch_notifications` has been deprecated and has no effect any more.

**5.5 Release**

**Kernel Launch Trace**

Two new commands, `info cuda launch trace` and `info cuda launch children`, are introduced to display the kernel launch trace and the children kernel of a given kernel when Dynamic Parallelism is used.

**Single-GPU Debugging (BETA)**

CUDA-GDB can now be used to debug a CUDA application on the same GPU that is rendering the desktop GUI. This feature also enables debugging of long-running or indefinite CUDA kernels that would otherwise encounter a launch timeout. In addition, multiple CUDA-GDB sessions can debug CUDA applications context-switching on the same GPU. This feature is available on Linux with SM3.5 devices. For information on enabling this, please see Single-GPU Debugging with the Desktop Manager Running and Multiple Debuggers.

**Remote GPU Debugging**

CUDA-GDB in conjunction with CUDA-GDBSERVER can now be used to debug a CUDA application running on the remote host.

**5.0 Release**

**Dynamic Parallelism Support**

CUDA-GDB fully supports Dynamic Parallelism, a new feature introduced with the 5.0 toolkit. The debugger is able to track the kernels launched from another kernel and to inspect and modify variables like any other CPU-launched kernel.
**Attach/Detach**

It is now possible to attach to a CUDA application that is already running. It is also possible to detach from the application before letting it run to completion. When attached, all the usual features of the debugger are available to the user, as if the application had been launched from the debugger. This feature is also supported with applications using Dynamic Parallelism.

**Attach on exception**

Using the environment variable `CUDA_DEVICE_WAITS_ON_EXCEPTION`, the application will run normally until a device exception occurs. Then the application will wait for the debugger to attach itself to it for further debugging.

**API Error Reporting**

Checking the error code of all the CUDA driver API and CUDA runtime API function calls is vital to ensure the correctness of a CUDA application. Now the debugger is able to report, and even stop, when any API call returns an error. See `set cuda api_failures` for more information.

**Inlined Subroutine Support**

Inlined subroutines are now accessible from the debugger on SM 2.0 and above. The user can inspect the local variables of those subroutines and visit the call frame stack as if the routines were not inlined.

**4.2 Release**

**Kepler Support**

The primary change in Release 4.2 of CUDA-GDB is the addition of support for the new Kepler architecture. There are no other user-visible changes in this release.

**4.1 Release**

**Source Base Upgraded to GDB 7.2**

Until now, CUDA-GDB was based on GDB 6.6 on Linux, and GDB 6.3.5 on Darwin (the Apple branch). Now, both versions of CUDA-GDB are using the same 7.2 source base.

Now CUDA-GDB supports newer versions of GCC (tested up to GCC 4.5), has better support for DWARF3 debug information, and better C++ debugging support.

**Simultaneous Sessions Support**

With the 4.1 release, the single CUDA-GDB process restriction is lifted. Now, multiple CUDA-GDB sessions are allowed to co-exist as long as the GPUs are not shared between the applications being processed. For instance, one CUDA-GDB process can debug process foo using GPU 0 while another CUDA-GDB process debugs process bar using GPU 1. The exclusive of GPUs can be enforced with the `CUDA_VISIBLE_DEVICES` environment variable.
New Autostep Command

A new ‘autostep’ command was added. The command increases the precision of CUDA exceptions by automatically single-stepping through portions of code.

Under normal execution, the thread and instruction where an exception occurred may be imprecisely reported. However, the exact instruction that generates the exception can be determined if the program is being single-stepped when the exception occurs.

Manually single-stepping through a program is a slow and tedious process. Therefore ‘autostep’ aides the user by allowing them to specify sections of code where they suspect an exception could occur. These sections are automatically single-stepped through when the program is running, and any exception that occurs within these sections is precisely reported.

Type ‘help autostep’ from CUDA-GDB for the syntax and usage of the command.

Multiple Context Support

On GPUs with compute capability of SM20 or higher, debugging multiple contexts on the same GPU is now supported. It was a known limitation until now.

Device Assertions Support

The R285 driver released with the 4.1 version of the toolkit supports device assertions. CUDA_GDB supports the assertion call and stops the execution of the application when the assertion is hit. Then the variables and memory can be inspected as usual. The application can also be resumed past the assertion if needed. Use the ‘set cuda hide_internal_frames’ option to expose/hide the system call frames (hidden by default).

Temporary Directory

By default, the debugger API will use /tmp as the directory to store temporary files. To select a different directory, the $TMPDIR environment variable and the API CUDADBG_APICLIENT_PID variable must be set.
Chapter 3. Getting Started

The CUDA toolkit can be installed by following instructions in the Quick Start Guide. Further steps should be taken to set up the debugger environment, build the application, and run the debugger.

3.1. Setting Up the Debugger Environment

3.1.1. Temporary Directory

By default, CUDA-GDB uses /tmp as the directory to store temporary files. To select a different directory, set the $TMPDIR environment variable.

**Note:** The user must have write and execute permission to the temporary directory used by CUDA-GDB. Otherwise, the debugger will fail with an internal error.

**Note:** Since /tmp folder does not exist on Android device, the $TMPDIR environment variable must be set and point to a user-writeable folder before launching cuda-gdb.

3.1.2. Using the CUDA-GDB debugger on Jetson and Drive Tegra devices

By default, on Jetson and Drive Tegra devices, GPU debugging is supported only if cuda-gdb and cuda-gdbserver are launched by a user who is a member of the debug group.

To add the current user to the debug group run this command:

```bash
sudo usermod -a -G debug $USER
```
3.2. Compiling the Application

3.2.1. Debug Compilation

NVCC, the NVIDIA CUDA compiler driver, provides a mechanism for generating the debugging information necessary for CUDA-GDB to work properly. The \(-g\) \(-G\) option pair must be passed to NVCC when an application is compiled for ease of debugging with CUDA-GDB; for example,

```
nvcc -g -G foo.cu -o foo
```

Using this line to compile the CUDA application `foo.cu`

- forces \(-O0\) compilation, with the exception of very limited dead-code eliminations and register-spilling optimizations.
- makes the compiler include debug information in the executable

To compile your CUDA Fortran code with debugging information necessary for CUDA-GDB to work properly, pgfortran, the PGI CUDA Fortran compiler, must be invoked with \(-g\) option. Also, for the ease of debugging and forward compatibility with the future GPU architectures, it is recommended to compile the code with \(-Mcuda=nordc\) option; for example,

```
pgfortran -g -Mcuda=nordc foo.cuf -o foo
```

For more information about the available compilation flags, please consult the PGI compiler documentation.

3.2.2. Compilation With Linenumber Information

Several enhancements were made to cuda-gdb’s support for debugging programs compiled with \(-lineinfo\) but not with \(-G\). This is intended primarily for debugging programs built with OptiX/RTCore.

Note that \(-lineinfo\) can be used when trying to debug optimized code. In this case, debugger stepping and breakpoint behavior may appear somewhat erratic.

- The PC may jump forward and backward unexpectedly while stepping.
- The user may step into code that has no linenumber information, leading to an inability to determine which source-file/linenumber the code at the PC belongs to.
- Breakpoints may break on a different line than they were originally set on.

When debugging OptiX/RTCore code, the following should be kept in mind:

- NVIDIA internal code cannot be debugged or examined by the user.
- OptiX/RTCode debugging is limited to \(-lineinfo\), and building this code with full debug information \(-g\) is not supported.
OptiX/RTC ode code is highly optimized, and as such the notes above about debugging optimized code apply.

### 3.2.3. Compiling For Specific GPU architectures

By default, the compiler will only generate code for the compute_52 PTX and sm_52 cubins. For later GPUs, the kernels are recompiled at runtime from the PTX for the architecture of the target GPU(s). Compiling for a specific virtual architecture guarantees that the application will work for any GPU architecture after that, for a trade-off in performance. This is done for forward-compatibility.

It is highly recommended to compile the application once and for all for the GPU architectures targeted by the application, and to generate the PTX code for the latest virtual architecture for forward compatibility.

A GPU architecture is defined by its compute capability. The list of GPUs and their respective compute capability, see [https://developer.nvidia.com/cuda-gpus](https://developer.nvidia.com/cuda-gpus). The same application can be compiled for multiple GPU architectures. Use the \texttt{-gencode} compilation option to dictate which GPU architecture to compile for. The option can be specified multiple times.

For instance, to compile an application for a GPU with compute capability 7.0, add the following flag to the compilation command:

\texttt{-gencode arch=compute\_70,code=sm\_70}

To compile PTX code for any future architecture past the compute capability 7.0, add the following flag to the compilation command:

\texttt{-gencode arch=compute\_70,code=compute\_70}

For additional information, please consult the compiler documentation at [http://docs.nvidia.com/cuda/cuda-compiler-driver-nvcc/index.html#extended-notation](http://docs.nvidia.com/cuda/cuda-compiler-driver-nvcc/index.html#extended-notation)

### 3.3. Using the Debugger

CUDA-GDB can be used in the following system configurations:

#### 3.3.1. Single-GPU Debugging with the Desktop Manager Running

For devices with compute capability 6.0 and higher CUDA-GDB can be used to debug CUDA applications on the same GPU that is running the desktop GUI.
Additionally for devices with compute capability less than 6.0 software preemption can be used to debug CUDA applications on the same GPU that is running the desktop GUI. There are two ways to enable this functionality:

- Use the following command:
  
  ```
  set cuda software_preemption on
  ```

- Export the following environment variable:

  ```
  CUDA_DEBUGGER_SOFTWARE_PREEMPTION=1
  ```

Either of the options above will activate software preemption. These options must be set prior to running the application. When the GPU hits a breakpoint or any other event that would normally cause the GPU to freeze, CUDA-GDB releases the GPU for use by the desktop or other applications. This enables CUDA-GDB to debug a CUDA application on the same GPU that is running the desktop GUI, and also enables debugging of multiple CUDA applications context-switching on the same GPU.

### 3.3.2. Multi-GPU Debugging

Multi-GPU debugging designates the scenario where the application is running on more than one CUDA-capable device. Multi-GPU debugging is not much different than single-GPU debugging except for a few additional CUDA-GDB commands that let you switch between the GPUs.

Any GPU hitting a breakpoint will pause all the GPUs running CUDA on that system. Once paused, you can use `info cuda kernels` to view all the active kernels and the GPUs they are running on. When any GPU is resumed, all the GPUs are resumed.

- **Note:** If the `CUDA_VISIBLE_DEVICES` environment is used, only the specified devices are suspended and resumed.

All CUDA-capable GPUs may run one or more kernels. To switch to an active kernel, use `cuda kernel <n>`, where `n` is the ID of the kernel retrieved from `info cuda kernels`.

- **Note:** The same kernel can be loaded and used by different contexts and devices at the same time. When a breakpoint is set in such a kernel, by either name or file name and line number, it will be resolved arbitrarily to only one instance of that kernel. With the runtime API, the exact instance to which the breakpoint will be resolved cannot be controlled. With the driver API, the user can control the instance to which the breakpoint will be resolved to by setting the breakpoint right after its module is loaded.
3.3.3. Remote Debugging

There are multiple methods to remote debug an application with CUDA-GDB. In addition to using SSH or VNC from the host system to connect to the target system, it is also possible to use the target remote GDB feature. Using this option, the local cuda-gdb (client) connects to the cuda-gdbserver process (the server) running on the target system. This option is supported with a Linux client and a Linux or QNX server.

Setting remote debugging that way is a 2-step process:

Launch the cuda-gdbserver on the remote host

cuda-gdbserver can be launched on the remote host in different operation modes.

▷ Option 1: Launch a new application in debug mode.

To launch a new application in debug mode, invoke cuda-gdb server as follows:

```bash
$ cuda-gdbserver :1234 app_invocation
```

Where 1234 is the TCP port number that cuda-gdbserver will listen to for incoming connections from cuda-gdb, and app-invocation is the invocation command to launch the application, arguments included.

▷ Option 2: Attach cuda-gdbserver to the running process

To attach cuda-gdbserver to an already running process, the --attach option followed by process identification number (PID) must be used:

```bash
$ cuda-gdbserver :1234 --attach 5678
```

Where 1234 is the TCP port number and 5678 is process identifier of the application cuda-gdbserver must be attached to.

Attaching to an already running process is not supported on QNX platforms.

Launch cuda-gdb on the client

Configure cuda-gdb to connect to the remote target using either:

```bash
(cuda-gdb) target remote
```

or

```bash
(cuda-gdb) target extended-remote
```

It is recommended to use set sysroot command if libraries installed on the debug target might differ from the ones installed on the debug host. For example, cuda-gdb could be configured to connect to remote target as follows:

```bash
(cuda-gdb) set sysroot remote://
(cuda-gdb) target remote 192.168.0.2:1234
```
Where 192.168.0.2 is the IP address or domain name of the remote target, and 1234 is the TCP port previously opened by `cuda-gdbserver`.

### 3.3.4. Multiple Debuggers

For devices with compute capability 6.0 and higher several debugging sessions may take place simultaneously.

For devices with compute capability less than 6.0, several debugging sessions may take place simultaneously as long as the CUDA devices are used exclusively. For instance, one instance of CUDA-GDB can debug a first application that uses the first GPU while another instance of CUDA-GDB debugs a second application that uses the second GPU. The exclusive use of a GPU is achieved by specifying which GPU is visible to the application by using the `CUDA_VISIBLE_DEVICES` environment variable.

```
$ CUDA_VISIBLE_DEVICES=1 cuda-gdb my_app
```

Additionally for devices with compute capability less than 6.0, with software preemption enabled (`set cuda software_preemption on`), multiple CUDA-GDB instances can be used to debug CUDA applications context-switching on the same GPU.

### 3.3.5. Attaching/Detaching

CUDA-GDB can attach to and detach from a CUDA application running on GPUs with compute capability 2.0 and beyond, using GDB’s built-in commands for attaching to or detaching from a process.

Additionally, if the environment variable `CUDA_DEVICE_WAITS_ON_EXCEPTION` is set to 1 prior to running the CUDA application, the application will run normally until a device exception occurs. The application will then wait for CUDA-GDB to attach itself to it for further debugging. This feature is not supported on WSL.

**Note:**

By default on some Linux distributions, the debugger cannot attach to an already running processes due to security settings. In order to enable the attach feature of the CUDA debugger, either `cuda-gdb` should be launched as root, or `/proc/sys/kernel/yama/ptrace_scope` should be set to zero, using the following command:

```
$ sudo sh -c "echo 0 >/proc/sys/kernel/yama/ptrace_scope"
```

To make the change permanent, edit `/etc/sysctl.d/10-ptrace.conf`. 
Chapter 4. CUDA-GDB Extensions

4.1. Command Naming Convention

The existing GDB commands are unchanged. Every new CUDA command or option is prefixed with the CUDA keyword. As much as possible, CUDA-GDB command names will be similar to the equivalent GDB commands used for debugging host code. For instance, the GDB command to display the host threads and switch to host thread 1 are, respectively:

```
(cuda-gdb) info threads
(cuda-gdb) thread 1
```

To display the CUDA threads and switch to cuda thread 1, the user only has to type:

```
(cuda-gdb) info cuda threads
(cuda-gdb) cuda thread 1
```

4.2. Getting Help

As with GDB commands, the built-in help for the CUDA commands is accessible from the cuda-gdb command line by using the help command:

```
(cuda-gdb) help cuda name_of_the_cuda_command
(cuda-gdb) help set cuda name_of_the_cuda_option
(cuda-gdb) help info cuda name_of_the_info_cuda_command
```

Moreover, all the CUDA commands can be auto-completed by pressing the TAB key, as with any other GDB command.

CUDA commands can also be queried using the `apropos` command.

4.3. Initialization File

The initialization file for CUDA-GDB is named `.cuda-gdbinit` and follows the same rules as the standard `.gdbinit` file used by GDB. The initialization file may contain any CUDA-GDB command. Those commands will be processed in order when CUDA-GDB is launched.
4.4. GUI Integration

Emacs

CUDA-GDB works with GUD in Emacs and XEmacs. No extra step is required other than pointing to the right binary.

To use CUDA-GDB, the gud-gdb-command-name variable must be set to cuda-gdb annotate=3. Use M-x customize-variable to set the variable.

Ensure that cuda-gdb is present in the Emacs/XEmacs $PATH.

DDD

CUDA-GDB works with DDD. To use DDD with CUDA-GDB, launch DDD with the following command:

```
ddd --debugger cuda-gdb
```

cuda-gdb must be in your $PATH.

4.5. GPU core dump support

Enabling GPU core dump generation on exception

Set the CUDA_ENABLE_COREDUMP_ON_EXCEPTION environment variable to 1 in order to enable generating a GPU core dump when a GPU exception is encountered. This option is disabled by default.

Set the CUDA_ENABLE_CPU_COREDUMP_ON_EXCEPTION environment variable to 0 in order to disable generating a CPU core dump when a GPU exception is encountered. This option is enabled by default when GPU core dump generation is enabled.

Note: CPU coredumps will be located in a distribution specific location. Examining the /proc/sys/kernel/core_pattern file will typically hint at the name/location of the CPU coredump.

Set the CUDA_ENABLE_LIGHTWEIGHT_COREDUMP environment variable to 1 in order to enable generating lightweight corefiles instead of full corefiles. When enabled, GPU core dumps will not contain the memory dumps (local, shared, global) of the application. This option is disabled by default.

On Volta-MPS, if an MPS client triggers a core dump, every other client running on the same MPS server will fault. The indirectly faulting clients will also generate a core dump if they have core dump generation enabled.
Naming of GPU core dump files

By default, a GPU core dump is created in the current working directory. It is named `core.cuda.HOSTNAME.PID` where `HOSTNAME` is the host name of the machine running the CUDA application and `PID` is the process identifier of the CUDA application.

The `CUDA_COREDUMP_FILE` environment variable can be used to define a template that is used to change the name of a GPU core dump file. The template can either be an absolute path or a relative path to the current working directory. The template can contain `%` specifiers which are substituted by the following patterns when a GPU core dump is created:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%h</td>
<td>Host name of the machine running the CUDA application</td>
</tr>
<tr>
<td>%p</td>
<td>Process identifier of the CUDA application</td>
</tr>
<tr>
<td>%t</td>
<td>Time as the number of seconds since the Epoch, 1970-01-01 00:00:00 +0000 (UTC)</td>
</tr>
</tbody>
</table>

As an example, setting `CUDA_COREDUMP_FILE` to:

```bash
eval CUDA_COREDUMP_FILE="newName.%h.%p"
```

Would result in GPU core dumps being written to `newName.myhost.1234` relative to the current working directory. Here `myhost` and `1234` are replaced with the real host name and pid respectively.

Setting `CUDA_COREDUMP_FILE` to:

```bash
eval CUDA_COREDUMP_FILE="/home/$USER/newName.%h.%p"
```

Would result in GPU core dumps being written to the user’s home directory with the same name logic as in the above example.

If `CUDA_COREDUMP_FILE` points to an existing file of FIFO type (e.g. named pipe), the coredump will be streamed to it.

Enabling user induced GPU core dump generation

For the devices that support compute preemption, the user can interrupt a running CUDA process to generate the GPU core dump.

Set the `CUDA_ENABLE_USER_TRIGGERED_COREDUMP` environment variable to 1 in order to enable generating a user induced GPU core dump. This option is disabled by default. Setting this environment variable will open a communication pipe for each subsequently running CUDA process. To induce the GPU core dump, the user simply writes to the pipe.

To change the default pipe file name, set the `CUDA_COREDUMP_PIPE` environment variable to a specific pipe name. The default pipe name is in the following format: `corepipe.cuda.HOSTNAME.PID` where `HOSTNAME` is the host name of machine running the
CUDA application and PID is the process identifier of the CUDA application. This environment variable can take % specifiers as described in the above section.

**Inspecting GPU and GPU+CPU core dumps in cuda-gdb**

Use the following command to load the GPU core dump into the debugger

```
(cuda-gdb) target cudacore core.cuda.localhost.1234
```

This will open the core dump file and print the exception encountered during program execution. Then, issue standard cuda-gdb commands to further investigate application state on the device at the moment it was aborted.

Use the following command to load CPU and GPU core dumps into the debugger

```
(cuda-gdb) target core core.cpu core.cuda
```

This will open the core dump file and print the exception encountered during program execution. Then, issue standard cuda-gdb commands to further investigate application state on the host and the device at the moment it was aborted.

**Note:** Coredump inspection does not require that a GPU be installed on the system
Chapter 5. Kernel Focus

A CUDA application may be running several host threads and many device threads. To simplify the visualization of information about the state of application, commands are applied to the entity in focus.

When the focus is set to a host thread, the commands will apply only to that host thread (unless the application is fully resumed, for instance). On the device side, the focus is always set to the lowest granularity level—the device thread.

5.1. Software Coordinates vs. Hardware Coordinates

A device thread belongs to a block, which in turn belongs to a kernel. Thread, block, and kernel are the software coordinates of the focus. A device thread runs on a lane. A lane belongs to a warp, which belongs to an SM, which in turn belongs to a device. Lane, warp, SM, and device are the hardware coordinates of the focus. Software and hardware coordinates can be used interchangeably and simultaneously as long as they remain coherent.

Another software coordinate is sometimes used: the grid. The difference between a grid and a kernel is the scope. The grid ID is unique per GPU whereas the kernel ID is unique across all GPUs. Therefore there is a 1:1 mapping between a kernel and a (grid, device) tuple.

Note: If software preemption is enabled (set cuda software preemption on), hardware coordinates corresponding to a device thread are likely to change upon resuming execution on the device. However, software coordinates will remain intact and will not change for the lifetime of the device thread.

5.2. Current Focus

To inspect the current focus, use the cuda command followed by the coordinates of interest:

(cuda-gdb) cuda device sm warp lane block thread
block (0,0,0), thread (0,0,0), device 0, sm 0, warp 0, lane 0
(cuda-gdb) cuda kernel block thread
kernel 1, block (0,0,0), thread (0,0,0)
(cuda-gdb) cuda kernel
kernel 1
5.3. Switching Focus

To switch the current focus, use the cuda command followed by the coordinates to be changed:

(cuda-gdb) cuda device 0 sm 1 warp 2 lane 3
[Switching focus to CUDA kernel 1, grid 2, block (8,0,0), thread (67,0,0), device 0, sm 1, warp 2, lane 3]
374 int totalThreads = gridDim.x * blockDim.x;

If the specified focus is not fully defined by the command, the debugger will assume that the omitted coordinates are set to the coordinates in the current focus, including the subcoordinates of the block and thread.

(cuda-gdb) cuda thread (15)
[Switching focus to CUDA kernel 1, grid 2, block (8,0,0), thread (15,0,0), device 0, sm 1, warp 0, lane 15]
374 int totalThreads = gridDim.x * blockDim.x;

The parentheses for the block and thread arguments are optional.

(cuda-gdb) cuda block 1 thread 3
[Switching focus to CUDA kernel 1, grid 2, block (1,0,0), thread (3,0,0), device 0, sm 3, warp 0, lane 3]
374 int totalThreads = gridDim.x * blockDim.
Chapter 6. Program Execution

Applications are launched the same way in CUDA-GDB as they are with GDB by using the run command. This chapter describes how to interrupt and single-step CUDA applications.

6.1. Interrupting the Application

If the CUDA application appears to be hanging or stuck in an infinite loop, it is possible to manually interrupt the application by pressing **CTRL+C**. When the signal is received, the GPUs are suspended and the `cuda-gdb` prompt will appear.

At that point, the program can be inspected, modified, single-stepped, resumed, or terminated at the user’s discretion.

This feature is limited to applications running within the debugger. It is not possible to break into and debug applications that have been launched outside the debugger.

6.2. Single Stepping

Single-stepping device code is supported. However, unlike host code single-stepping, device code single-stepping works at the warp level. This means that single-stepping a device kernel advances all the active threads in the warp currently in focus. The divergent threads in the warp are not single-stepped.

In order to advance the execution of more than one warp, a breakpoint must be set at the desired location and then the application must be fully resumed.

A special case is single-stepping over thread barrier calls like `__syncthreads()` or cluster-wide barriers. In this case, an implicit temporary breakpoint is set immediately after the barrier and all threads are resumed until the temporary breakpoint is hit.

You can step in, over, or out of the device functions as long as they are not inlined. To force a function to not be inlined by the compiler, the `__noinline__` keyword must be added to the function declaration.

Asynchronous SASS instructions executed on the device, such as the warpgroup instructions, at prior PCs are not guaranteed to be complete.

With Dynamic Parallelism, several CUDA APIs can be called directly from device code. The following list defines single-step behavior when encountering these APIs:
When encountering device side kernel launches (denoted by the `<<<>>>` launch syntax),
the step and next commands will have the same behavior, and both will step over the
launch call.

On devices prior to Hopper [SM 9.0], stepping into the deprecated
`cudaDeviceSynchronize()` results in undefined behavior. Users shall step over this call
instead.

When stepping a device grid launch to completion, focus will automatically switch back to
the CPU. The `cuda_kernel` focus switching command must be used to switch to another
grid of interest (if one is still resident).

**Note:** It is not possible to step into a device launch call (nor the routine launched by the call).
Chapter 7. Breakpoints & Watchpoints

There are multiple ways to set a breakpoint on a CUDA application. These methods are described below. The commands used to set a breakpoint on device code are the same as the commands used to set a breakpoint on host code.

If a breakpoint is set on device code, the breakpoint will be marked pending until the ELF image of the kernel is loaded. At that point, the breakpoint will be resolved and its address will be updated.

When a breakpoint is set, it forces all resident GPU threads to stop at this location when it reaches the corresponding PC.

When a breakpoint is hit by one thread, there is no guarantee that the other threads will hit the breakpoint at the same time. Therefore the same breakpoint may be hit several times, and the user must be careful with checking which thread(s) actually hit(s) the breakpoint. The disable command can be used to prevent hitting the breakpoint by additional threads.

### 7.1. Symbolic Breakpoints

To set a breakpoint at the entry of a function, use the `break` command followed by the name of the function or method:

```
(cuda-gdb) break my_function
(cuda-gdb) break my_class::my_method
```

For templatized functions and methods, the full signature must be given:

```
(cuda-gdb) break int my_templatized_function<int>(int)
```

The mangled name of the function can also be used. To find the mangled name of a function, you can use the following command:

```
(cuda-gdb) set demangle-style none
(cuda-gdb) info function my_function_name
(cuda-gdb) set demangle-style auto
```

### 7.2. Line Breakpoints

To set a breakpoint on a specific line number, use the following syntax:
If the specified line corresponds to an instruction within templatized code, multiple breakpoints will be created, one for each instance of the templatized code.

7.3. Address Breakpoints

To set a breakpoint at a specific address, use the `break` command with the address as argument:

```
(cuda-gdb) break *0x1afe34d0
```

The address can be any address on the device or the host.

7.4. Kernel Entry Breakpoints

To break on the first instruction of every launched kernel, set the `break_on_launch` option to application:

```
(cuda-gdb) set cuda break_on_launch application
```

See `set cuda break_on_launch` for more information.

7.5. Conditional Breakpoints

To make the breakpoint conditional, use the optional `if` keyword or the `cond` command.

```
(cuda-gdb) break foo.cu:23 if threadIdx.x == 1 && i < 5
(cuda-gdb) cond 3 threadIdx.x == 1 && i < 5
```

Conditional expressions may refer any variable, including built-in variables such as `threadIdx` and `blockIdx`. Function calls are not allowed in conditional expressions.

Note that conditional breakpoints are always hit and evaluated, but the debugger reports the breakpoint as being hit only if the conditional statement is evaluated to TRUE. The process of hitting the breakpoint and evaluating the corresponding conditional statement is time-consuming. Therefore, running applications while using conditional breakpoints may slow down the debugging session. Moreover, if the conditional statement is always evaluated to FALSE, the debugger may appear to be hanging or stuck, although it is not the case. You can interrupt the application with **CTRL-C** to verify that progress is being made.

Conditional breakpoints can be set on code from CUDA modules that are not already loaded. The verification of the condition will then only take place when the ELF image of that module is loaded. Therefore any error in the conditional expression will be deferred until the CUDA module is loaded. To double check the desired conditional expression, first set an unconditional breakpoint at the desired location and continue. When the breakpoint is hit, evaluate the desired conditional statement by using the `cond` command.
7.6. Watchpoints

Watchpoints on CUDA code are not supported.

Watchpoints on host code are supported. The user is invited to read the GDB documentation for a tutorial on how to set watchpoints on host code.
Chapter 8.  Inspecting Program State

8.1.  Memory and Variables

The GDB print command has been extended to decipher the location of any program variable and can be used to display the contents of any CUDA program variable including:

- data allocated via cudaMalloc()
- data that resides in various GPU memory regions, such as shared, local, and global memory
- special CUDA runtime variables, such as threadIdx

8.2.  Variable Storage and Accessibility

Depending on the variable type and usage, variables can be stored either in registers or in local, shared, const or global memory. You can print the address of any variable to find out where it is stored and directly access the associated memory.

The example below shows how the variable array, which is of type shared int *, can be directly accessed in order to see what the stored values are in the array.

(cuda-gdb) print &array
$1 = (@shared int *)[0]) 0x20
(cuda-gdb) print array[0]@4
$2 = {0, 128, 64, 192}

You can also access the shared memory indexed into the starting offset to see what the stored values are:

(cuda-gdb) print *(@shared int*)0x20
$3 = 0
(cuda-gdb) print *(@shared int*)0x24
$4 = 128
(cuda-gdb) print *(@shared int*)0x28
$5 = 64

The example below shows how to access the starting address of the input parameter to the kernel.
8.3. Info CUDA Commands

These are commands that display information about the GPU and the application’s CUDA state. The available options are:

- **devices**: information about all the devices
- **sms**: information about all the active SMs in the current device
- **warps**: information about all the active warps in the current SM
- **lanes**: information about all the active lanes in the current warp
- **kernels**: information about all the active kernels
- **blocks**: information about all the active blocks in the current kernel
- **threads**: information about all the active threads in the current kernel
- **launch trace**: information about the parent kernels of the kernel in focus
- **launch children**: information about the kernels launched by the kernels in focus
- **contexts**: information about all the contexts

A filter can be applied to every `info cuda` command. The filter restricts the scope of the command. A filter is composed of one or more restrictions. A restriction can be any of the following:

- `device n`
- `sm n`
- `warp n`
- `lane n`
- `kernel n`
- `grid n`
- `block x[,y]` or `block (x[,y])`
- `thread x[,y[,z]]` or `thread (x[,y[,z]])`
- `breakpoint all` and `breakpoint n`
where \( n, x, y, z \) are integers, or one of the following special keywords: `current`, `any`, and `all`. current indicates that the corresponding value in the current focus should be used. any and all indicate that any value is acceptable.

Note: The breakpoint `all` and breakpoint `n` filter are only effective for the `info cuda threads` command.

### 8.3.1. info cuda devices

This command enumerates all the GPUs in the system sorted by device index. A * indicates the device currently in focus. This command supports filters. The default is `device all`. This command prints No CUDA Devices if no active GPUs are found. A device is not considered active until the first kernel launch has been encountered.

<table>
<thead>
<tr>
<th>Device PCI Bus/Dev ID</th>
<th>Name</th>
<th>Description</th>
<th>SM Type</th>
<th>SMs Warps/SM Lanes</th>
<th>Active SMs</th>
</tr>
</thead>
<tbody>
<tr>
<td>* 0 65:00.0</td>
<td>NVIDIA GeForce RTX 3070</td>
<td>GA104-A</td>
<td>sm_86</td>
<td>46</td>
<td>48</td>
</tr>
</tbody>
</table>

### 8.3.2. info cuda sms

This command shows all the SMs for the device with active warps. This command supports filters and the default is `device current sm all`. A * indicates the SM in focus. The results are grouped per device. SMs without active warps are omitted from the output.

### 8.3.3. info cuda warps

This command prints all the active warps for the SM in focus. This command supports filters and the default is `device current sm current warp all`. The command can be used to display which warp executes what block. Warps without active lanes are omitted from the output.

8.3.4. info cuda lanes

This command displays all the active lanes (threads) for the warp in focus. This command supports filters and the default is `device current sm current warp current lane all`. If an exception occurred in the active lane, the name of the exception is displayed. None is displayed for no exception. This command can be used to display which lane executes what thread. Inactive lanes are omitted from the output. In the example below, you can see that all the lanes are at the same physical PC and encountered the same exception.

```
(cuda-gdb) info cuda lanes
Ln  State     Physical PC    ThreadIdx        Exception
Device 0 SM 0 Warp 29
  *  0 active 0x00000001           0xfffffffe 0x00000000000002d0      0  (0,0,0)
  1        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
  2        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
  3        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
  4        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
  5        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
  6        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
  7        0xffffffff           0x00000000 0x00000000000004b0      0  (0,0,0)
...
```

8.3.5. info cuda kernels

This command displays all the active kernels on the GPU in focus. It prints the kernel ID, parent kernel ID, device ID, grid ID, and SM mask for each kernel with the associated dimensions and invocation. The kernel ID is unique across all GPUs whereas the grid ID is unique per GPU. The Parent column shows the kernel ID of the parent grid. This command supports filters and the default is `kernel all`.

```
(cuda-gdb) info cuda kernels
Kernel Parent Dev Grid Status   SMs Mask GridDim BlockDim Invocation
  *      0      -   0    1 Active 0x00000000000000004d0 (928,0,0) (929,0,0) Warp Misaligned Address
  1 active 0x00000000000000004d0 (929,0,0) Warp Misaligned Address
  2 active 0x00000000000000004d0 (930,0,0) Warp Misaligned Address
  3 active 0x00000000000000004d0 (931,0,0) Warp Misaligned Address
  4 active 0x00000000000000004d0 (932,0,0) Warp Misaligned Address
...
```

This command will also show grids that have been launched on the GPU with Dynamic Parallelism. Kernels with a negative grid ID have been launched from the GPU, while kernels with a positive grid ID have been launched from the CPU.
8.3.6. info cuda blocks

This command displays all the active or running blocks for the kernel in focus. The results are grouped per kernel. This command supports filters and the default is kernel current block all. The outputs are coalesced by default.

```
(cuda-gdb) info cuda blocks
  BlockIdx To BlockIdx Count   State
Kernel 0
  * (0,0,0)    (45,0,0)    46 running
```

Coalescing can be turned off as follows in which case more information on the Device and the SM get displayed:

```
(cuda-gdb) set cuda coalescing off
```

The following is the output of the same command when coalescing is turned off.

```
(cuda-gdb) info cuda blocks
  BlockIdx   State Dev SM
Kernel 0
  * (0,0,0) running   0  0
  (1,0,0) running   0  2
  (2,0,0) running   0  4
  (3,0,0) running   0  6
  (4,0,0) running   0  8
  (5,0,0) running   0 10
  (6,0,0) running   0 12
  (7,0,0) running   0 14
  (8,0,0) running   0 16
...```

8.3.7. info cuda threads

This command displays the application’s active CUDA blocks and threads with the total count of threads in those blocks. Also displayed are the virtual PC and the associated source file and the line number information. The results are grouped per kernel. The command supports filters with default being kernel current block all thread all. The outputs are coalesced by default as follows:

```
(cuda-gdb) info cuda threads
  BlockIdx ThreadIdx To BlockIdx To ThreadIdx Count         Virtual PC Filename  Line
Kernel 0
  * (0,0,0)   (0,0,0)     (0,0,0)     (31,0,0)    32 0x0000555555c576b0  acos.cu
            332
  (0,0,0)  (32,0,0)     (7,0,0)     (32,0,0)   232 0x0000555555c57670  acos.cu
            331
...
```

Coalescing can be turned off as follows in which case more information is displayed with the output.

```
(cuda-gdb) info cuda threads
  BlockIdx ThreadIdx         Virtual PC Dev SM Wp Ln Filename  Line
Kernel 0
```
Inspecting Program State

Note: In coalesced form, threads must be contiguous in order to be coalesced. If some threads are not currently running on the hardware, they will create holes in the thread ranges. For instance, if a kernel consist of 2 blocks of 16 threads, and only the 8 lowest threads are active, then 2 coalesced ranges will be printed: one range for block 0 thread 0 to 7, and one range for block 1 thread 0 to 7. Because threads 8-15 in block 0 are not running, the 2 ranges cannot be coalesced.

The command also supports `breakpoint all` and `breakpoint breakpoint_number` as filters. The former displays the threads that hit all CUDA breakpoints set by the user. The latter displays the threads that hit the CUDA breakpoint `breakpoint_number`.

```
(cuda-gdb) info cuda threads breakpoint all
    BlockIdx ThreadIdx To BlockIdx To ThreadIdx Count         Virtual PC
    Filename  Line
    Kernel 0
*  (0,0,0)   (0,0,0)     (1,0,0)     (15,0,0)    32 0x00005555555c39530
    infoCommands.cu 12

(cuda-gdb) info cuda threads breakpoint 1 lane 1
    BlockIdx ThreadIdx To BlockIdx To ThreadIdx Count         Virtual PC
    Filename  Line
    Kernel 0
  (1,0,0)   (1,0,0)     (1,0,0)      (1,0,0)     1 0x00005555555c39530
    infoCommands.cu 12
  (1,0,0)   (0,0,0) (1,0,0)      (1,0,0)     1 0x00005555555c39530
    infoCommands.cu 12
```

### 8.3.8. info cuda launch trace

This command displays the kernel launch trace for the kernel in focus. The first element in the trace is the kernel in focus. The next element is the kernel that launched this kernel. The trace continues until there is no parent kernel. In that case, the kernel is CPU-launched.

For each kernel in the trace, the command prints the level of the kernel in the trace, the kernel ID, the device ID, the grid ID, the status, the kernel dimensions, the kernel name, and the kernel arguments.

```
(cuda-gdb) info cuda launch trace
    Lvl Kernel Dev Grid   Status GridDim BlockDim Invocation
* #0  3  0   -7  Active  (1,1,1)  (1,1,1) kernel4()
#1  2  0  -6  Sleeping  (1,1,1)  (1,1,1) kernel3()
#2  1  0  -5  Sleeping  (1,1,1)  (1,1,1) kernel2()
#3  0  0   2  Sleeping  (1,1,1)  (1,1,1) kernel1()
```
A kernel that has been launched but that is not running on the GPU will have a Pending status. A kernel currently running on the GPU will be marked as Active. A kernel waiting to become active again will be displayed as Sleeping. When a kernel has terminated, it is marked as Terminated. For the few cases, when the debugger cannot determine if a kernel is pending or terminated, the status is set to Undetermined.

This command supports filters and the default is kernel all.

**Note:** With set cuda software_preemption on, no kernel will be reported as active.

### 8.3.9. info cuda launch children

This command displays the list of non-terminated kernels launched by the kernel in focus. For each kernel, the kernel ID, the device ID, the grid ID, the kernel dimensions, the kernel name, and the kernel parameters are displayed.

```
(cuda-gdb) info cuda launch children
Kernel Dev Grid Status GridDim BlockDim Invocation
*      3   0   -7 Active (1,1,1)  (1,1,1) kernel5(a=3)
18   0   -8 Active (1,1,1) (32,1,1) kernel4(b=5)
```

This command supports filters and the default is kernel all.

### 8.3.10. info cuda contexts

This command enumerates all the CUDA contexts running on all GPUs. A * indicates the context currently in focus. This command shows whether a context is currently active on a device or not.

```
(cuda-gdb) info cuda contexts
Context Dev State
0x00000000080b9518   0 inactive
* 0x0000000008067948   0 active
```

### 8.3.11. info cuda managed

This command shows all the static managed variables on the device or on the host depending on the focus.

```
(cuda-gdb) info cuda managed
Static managed variables on device 0 are:
managed_var = 3
managed_consts = {one = 1, e = 2.71000004, pi = 3.1400000000000001}
```

### 8.4. Disassembly

The device SASS code can be disassembled using the standard GDB disassembly instructions such as x/i and display/i.
Inspecting Program State

Note: For disassembly instruction to work properly, cuobjdump must be installed and present in your $PATH.

In the disassembly view, the current pc is prefixed with =>. For Maxwell (SM 5.0) and newer architectures, if an instruction triggers an exception it will be prefixed with *>. If the pc and errorpc are the same instruction it will be prefixed with *=>.

For example, consider the following exception:

CUDA Exception: Warp Illegal Address
The exception was triggered at PC 0x555555c08620 (memexceptions_kernel.cu:17)
Thread 1 "memexceptions" received signal CUDA_EXCEPTION_14, Warp Illegal Address.
[Switching focus to CUDA kernel 0, grid 1, block (0,0,0), thread (0,0,0), device 0, sm 0, warp 0, lane 0]
0x0000555555c08fb0 in exception_kernel<<<(1,1,1),(1,1,1)>>> (data=0x7fffccc00000, exception=MMU_FAULT) at memexceptions_kernel.cu:50
50 }
(cuda-gdb)

The disas command can be used to view both the PC and the error PC that triggered the exception.

(cuda-gdb) disas $pc,+16
Dump of assembler code from 0x555555c08fb0 to 0x555555c08fc0:
=> 0x0000555555c08fb0 <_Z16exception_kernelPv11exception_t+3504>: ERRBAR
End of assembler dump.

(cuda-gdb) disas $errorpc,+16
Dump of assembler code from 0x555555c08620 to 0x555555c08630:
*> 0x0000555555c08620 <_Z16exception_kernelPv11exception_t+1056>: ST.E.U8.STRONG.SYS [R6.64], R5
End of assembler dump.

8.5. Registers

The device registers code can be inspected/modified using the standard GDB commands such as info registers.

(cuda-gdb) info registers $R0 $R1 $R2 $R3
R0 0xf0 240
R1 0xffffc48 16776264
R2 0x7800 30720
R3 0x80 128

The registers are also accessible as $R<regnum> built-in variables, for example:

(cuda-gdb) printf "%d %d\n", $R0*$R3, $R2
30720 30720
Values of predicate and CC registers can be inspecting by printing system registers group or by using their respective pseudo-names: \$P0..\$P6 and \$CC.

<table>

</tbody>
</table>
Chapter 9. Event Notifications

As the application is making forward progress, CUDA-GDB notifies the users about kernel events and context events. Within CUDA-GDB, *kernel* refers to the device code that executes on the GPU, while *context* refers to the virtual address space on the GPU for the kernel. You can enable output of CUDA context and kernel events to review the flow of the active contexts and kernels. By default, only context event messages are displayed.

9.1. Context Events

Any time a CUDA context is created, pushed, popped, or destroyed by the application, CUDA-GDB can optionally display a notification message. The message includes the context id and the device id to which the context belongs.

```
[Context Create of context 0xad2fe60 on Device 0]
[Context Destroy of context 0xad2fe60 on Device 0]
```

By default, context event notification is disabled. The context event notification policy is controlled with the `context_events` option.

- `(cuda-gdb) set cuda context_events off`
  
  CUDA-GDB does not display the context event notification messages (default).

- `(cuda-gdb) set cuda context_events on`
  
  CUDA-GDB displays the context event notification messages.

9.2. Kernel Events

Any time CUDA-GDB is made aware of the launch or the termination of a CUDA kernel, a notification message can be displayed. The message includes the kernel id, the kernel name, and the device to which the kernel belongs.

```
[Launch of CUDA Kernel 1 (kernel3) on Device 0]
[Termination of CUDA Kernel 1 (kernel3) on Device 0]
```

The kernel event notification policy is controlled with `kernel_events` and `kernel_events_depth` options.
(cuda-gdb) set cuda kernel_events none

Possible options are:

none
  no kernel, application or system (default)

application
  kernel launched by the user application

system
  any kernel launched by the driver, such as memset

all
  any kernel, application and system

(cuda-gdb) set cuda kernel_events_depth 0

Controls the maximum depth of the kernels after which no kernel event notifications will be displayed. A value of zero means that there is no maximum and that all the kernel notifications are displayed. A value of one means that the debugger will display kernel event notifications only for kernels launched from the CPU (default).
Chapter 10. Automatic Error Checking

10.1. Checking API Errors

CUDA-GDB can automatically check the return code of any driver API or runtime API call. If the return code indicates an error, the debugger will stop or warn the user.

The behavior is controlled with the set cuda_api_failures option. Three modes are supported:

- **hide** will not report any error of any kind
- **ignore** will emit a warning but continue the execution of the application (default)
- **stop** will emit an error and stop the application

**Note:** The success return code and other non-error return codes are ignored. For the driver API, those are: CUDA_SUCCESS and CUDA_ERROR_NOT_READY. For the runtime API, they are cudaSuccess and cudaErrorNotReady.

10.2. GPU Error Reporting

The following table shows the errors that are reported on GPUs with compute capability sm_50 and higher.

For exceptions that are not precise, such as cluster exceptions, the autostep command can be used to extract the exact block and instruction causing the error. See Autostep for more information.

**Note:** Continuing the execution of your application after these errors are found can lead to application termination or indeterminate results.
### Table 1. CUDA Exception Codes

<table>
<thead>
<tr>
<th>Exception Code</th>
<th>Precision of the Error</th>
<th>Scope of the Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUDA_EXCEPTION_0 : &quot;Device Unknown Exception&quot;</td>
<td>Unknown</td>
<td>Global error on the GPU</td>
<td>This is a global GPU error caused by the application which does not match any of the listed error codes below. This should be a rare occurrence. Potentially, this may be due to Device Hardware Stack overflows or a kernel generating an exception very close to its termination.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_1 : &quot;Deprecated&quot;</td>
<td>Deprecated</td>
<td>Deprecated</td>
<td>This exception is deprecated and should be treated as CUDA_EXCEPTION_0.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_2 : &quot;Lane User Stack Overflow&quot;</td>
<td>Precise</td>
<td>Per lane/thread error</td>
<td>This occurs when a thread exceeds its stack memory limit.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_3 : &quot;Device Hardware Stack Overflow&quot;</td>
<td>Precise</td>
<td>Global error on the GPU</td>
<td>This occurs when the application triggers a global hardware stack overflow. The main cause of this error is large amounts of divergence in the presence of function calls.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_4 : &quot;Warp Illegal Instruction&quot;</td>
<td>Precise</td>
<td>Warp error</td>
<td>This occurs when any thread within a warp has executed an illegal instruction.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_5 : &quot;Warp Out-of-range Address&quot;</td>
<td>Precise</td>
<td>Warp error</td>
<td>This occurs when any thread within a warp accesses an address that is outside the valid range of local or shared memory regions.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_6 : &quot;Warp Misaligned Address&quot;</td>
<td>Precise</td>
<td>Warp error</td>
<td>This occurs when any thread within a warp accesses an address in the local or shared memory segments that is not correctly aligned.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_7 : &quot;Warp Invalid Address Space&quot;</td>
<td>Precise</td>
<td>Warp error</td>
<td>This occurs when any thread within a warp executes an instruction that accesses a memory space not permitted for that instruction.</td>
</tr>
<tr>
<td>Exception Code</td>
<td>Precision of the Error</td>
<td>Scope of the Error</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>------------------------</td>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_8 : &quot;Warp Invalid PC&quot;</td>
<td>Precise</td>
<td>Warp error</td>
<td>This occurs when any thread within a warp advances its PC beyond the 40-bit address space.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_9 : &quot;Warp Hardware Stack Overflow&quot;</td>
<td>Precise</td>
<td>Warp error</td>
<td>This occurs when any thread in a warp triggers a hardware stack overflow. This should be a rare occurrence.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_10 : &quot;Device Illegal Address&quot;</td>
<td>Precise</td>
<td>Global error</td>
<td>This occurs when a thread accesses an illegal[out of bounds] global address.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_11 : &quot;Deprecated&quot;</td>
<td>Deprecated</td>
<td>Deprecated</td>
<td>This exception is deprecated and should be treated as CUDA_EXCEPTION_0.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_12 : &quot;Warp Assert&quot;</td>
<td>Precise</td>
<td>Per warp</td>
<td>This occurs when any thread in the warp hits a device side assertion.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_13 : &quot;Deprecated&quot;</td>
<td>Deprecated</td>
<td>Deprecated</td>
<td>This exception is deprecated and should be treated as CUDA_EXCEPTION_0.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_14 : &quot;Warp Illegal Address&quot;</td>
<td>Precise</td>
<td>Per warp</td>
<td>This occurs when a thread accesses an illegal[out of bounds] global/local/shared address.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_15 : &quot;Invalid Managed Memory Access&quot;</td>
<td>Precise</td>
<td>Per host thread</td>
<td>This occurs when a host thread attempts to access managed memory currently used by the GPU.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_16 : &quot;Deprecated&quot;</td>
<td>Deprecated</td>
<td>Deprecated</td>
<td>This exception is deprecated and should be treated as CUDA_EXCEPTION_0.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_17 : &quot;Cluster Out-of-range Address&quot;</td>
<td>Not precise</td>
<td>Per Cuda Cluster</td>
<td>This occurs when any thread within a block accesses an address that is outside the valid range of shared memory regions belonging to the cluster.</td>
</tr>
<tr>
<td>CUDA_EXCEPTION_18 : &quot;Cluster Target Block Not Present&quot;</td>
<td>Not precise</td>
<td>Per Cuda Cluster</td>
<td>This occurs when any thread within a block accesses another block that is outside the valid range of blocks belonging to the cluster.</td>
</tr>
</tbody>
</table>
10.3. Autostep

Autostep is a command to increase the precision of CUDA exceptions to the exact lane and instruction, when they would not have been otherwise.

Under normal execution, an exception may be reported several instructions after the exception occurred, or the exact thread where an exception occurred may not be known unless the exception is a lane error. However, the precise origin of the exception can be determined if the program is being single-stepped when the exception occurs. Single-stepping manually is a slow and tedious process; stepping takes much longer than normal execution and the user has to single-step each warp individually.

Autostep aides the user by allowing them to specify sections of code where they suspect an exception could occur, and these sections are automatically and transparently single-stepped the program is running. The rest of the program is executed normally to minimize the slow-down caused by single-stepping. The precise origin of an exception will be reported if the exception occurs within these sections. Thus the exact instruction and thread where an exception occurred can be found quickly and with much less effort by using autostep.

Autostep Usage

`autostep [LOCATION]`
`autostep [LOCATION] for LENGTH [lines|instructions]`

- **LOCATION** may be anything that you use to specify the location of a breakpoint, such as a line number, function name, or an instruction address preceded by an asterisk. If no LOCATION is specified, then the current instruction address is used.

- **LENGTH** specifies the size of the autostep window in number of lines or instructions (*lines* and *instructions* can be shortened, e.g., *l* or *i*). If the length type is not specified, then *lines* is the default. If the for clause is omitted, then the default is 1 line.

- **astep** can be used as an alias for the *autostep* command.

- Calls to functions made during an autostep will be stepped over.

- In case of divergence, the length of the autostep window is determined by the number of lines or instructions the first active lane in each warp executes. Divergent lanes are also single stepped, but the instructions they execute do not count towards the length of the autostep window.

- If a breakpoint occurs while inside an autostep window, the warp where the breakpoint was hit will not continue autostepping when the program is resumed. However, other warps may continue autostepping.

- Overlapping autosteps are not supported.
If an autostep is encountered while another autostep is being executed, then the second autostep is ignored.

If an autostep is set before the location of a memory error and no memory error is hit, then it is possible that the chosen window is too small. This may be caused by the presence of function calls between the address of the autostep location and the instruction that triggers the memory error. In that situation, either increase the size of the window to make sure that the faulty instruction is included, or move to the autostep location to an instruction that will be executed closer in time to the faulty instruction.

Related Commands

Autosteps and breakpoints share the same numbering so most commands that work with breakpoints will also work with autosteps.

```
info autosteps
```
shows all breakpoints and autosteps. It is similar to `info breakpoints`.

```
(cuda-gdb) info autosteps
Num Type  Disp Enb Address What
1    autostep keep y   0x0000000000401234 in merge at sort.cu:30 for 49 instructions
3    autostep keep y   0x0000000000489913 in bubble at sort.cu:94 for 11 lines
```

disable autosteps disables an autostep. It is equivalent to `disable breakpoints n`.
delete autosteps n deletes an autostep. It is equivalent to `delete breakpoints n`.
ignore n i tells the debugger to not single-step the next i times the debugger enters the window for autostep n. This command already exists for breakpoints.
Chapter 11. Walk-Through Examples

The chapter contains two CUDA-GDB walk-through examples:

- **Example: bitreverse**
- **Example: autostep**
- **Example: MPI CUDA Application**

### 11.1. Example: bitreverse

This section presents a walk-through of CUDA-GDB by debugging a sample application—called `bitreverse`—that performs a simple 8 bit reversal on a data set.

Source Code

```c
#include <stdio.h>
#include <stdlib.h>

// Simple 8-bit bit reversal Compute test

#define N 256

__global__ void bitreverse(void *data) {
    unsigned int *idata = (unsigned int*)data;
    extern __shared__ int array[];

    array[threadIdx.x] = idata[threadIdx.x];

    array[threadIdx.x] = ((0xf0f0f0f0 & array[threadIdx.x]) >> 4) |
                        ((0x0f0f0f0f & array[threadIdx.x]) << 4);
    array[threadIdx.x] = ((0xcccccccc & array[threadIdx.x]) >> 2) |
                        ((0x33333333 & array[threadIdx.x]) << 2);
    array[threadIdx.x] = ((0xaaaaaaaa & array[threadIdx.x]) >> 1) |
                        ((0x55555555 & array[threadIdx.x]) << 1);

    idata[threadIdx.x] = array[threadIdx.x];
}

int main(void) {
    void *d = NULL; int i;
    unsigned int idata[N], odata[N];

    for (i = 0; i < N; i++)
        idata[i] = (unsigned int)i;
```
11.1.1. Walking through the Code

1. Begin by compiling the `bitreverse.cu` CUDA application for debugging by entering the following command at a shell prompt:

   ```bash
   $ nvcc -g -G bitreverse.cu -o bitreverse
   ```

   This command assumes that the source file name is `bitreverse.cu` and that no additional compiler flags are required for compilation. See also Debug Compilation

2. Start the CUDA debugger by entering the following command at a shell prompt:

   ```bash
   $ cuda-gdb bitreverse
   ```

3. Set breakpoints. Set both the host (main) and GPU (bitreverse) breakpoints here. Also, set a breakpoint at a particular line in the device function (bitreverse.cu:18).

   ```
   (cuda-gdb) break main
   Breakpoint 1 at 0x18e1: file bitreverse.cu, line 25.
   (cuda-gdb) break bitreverse
   Breakpoint 2 at 0x18a1: file bitreverse.cu, line 8.
   (cuda-gdb) break 21
   Breakpoint 3 at 0x18ac: file bitreverse.cu, line 21.
   ```

4. Run the CUDA application, and it executes until it reaches the first breakpoint (main) set in 3.

   ```
   (cuda-gdb) run
   Starting program: /Users/CUDA_User1/docs/bitreverse
   Reading symbols for shared libraries
   .+........................................................... done
   Breakpoint 1, main () at bitreverse.cu:25
   25  void *d = NULL; int i;
   ```

5. At this point, commands can be entered to advance execution or to print the program state. For this walkthrough, let’s continue until the device kernel is launched.

   ```
   (cuda-gdb) continue
   Continuing.
   Reading symbols for shared libraries .. done
   Reading symbols for shared libraries .. done
   [Context Create of context 0x80f200 on Device 0]
   [Launch of CUDA Kernel 0 (bitreverse<<<(1,1,1),(256,1,1)>>>) on Device 0]
   Breakpoint 3 at 0x8667b8: file bitreverse.cu, line 21.
   [Switching focus to CUDA kernel 0, grid 1, block (0,0,0), thread (0,0,0), device 0, sm 0, warp 0, lane 0]
Breakpoint 2, bitreverse<<<(1,1,1),(256,1,1)>>> (data=0x110000) at bitreverse.cu:9
9 unsigned int *idata = (unsigned int*)data;

CUDA-GDB has detected that a CUDA device kernel has been reached. The debugger prints the current CUDA thread of focus.

6. Verify the CUDA thread of focus with the info cuda threads command and switch between host thread and the CUDA threads:

(cuda-gdb) info cuda threads
BlockIdx ThreadIdx To BlockIdx ThreadIdx Count Virtual PC Filename Line
Kernel 0 * (0,0,0) (0,0,0) (0,0,0) (255,0,0) 256 0x0000000000866400 bitreverse.cu 9
(cuda-gdb) thread 1
[Current thread is 1 (process 16738)]
(cuda-gdb) thread 1
[Switching to thread 1 (process 16738)]
#0 0x0000019d in main () at bitreverse.cu:34
34 bitreverse<<<1, N, N*sizeof(int)>>>(d);
(cuda-gdb) backtrace
#0 0x0000019d in main () at bitreverse.cu:34
(cuda-gdb) info cuda kernels
Kernel Dev Grid SMs Mask GridDim BlockDim Name Args
0 0 1 0x00000001 (1,1,1) (256,1,1) bitreverse data=0x110000
(cuda-gdb) cuda kernel 0
[Switching focus to CUDA kernel 0, grid 1, block (0,0,0), thread (0,0,0), device 0, sm 0, warp 0, lane 0]
9 unsigned int *idata = (unsigned int*)data;
(cuda-gdb) backtrace
#0 bitreverse<<<(1,1,1),(256,1,1)>>> (data=0x110000) at bitreverse.cu:9

7. Corroborate this information by printing the block and thread indexes:

(cuda-gdb) print blockIdx
$1 = {x = 0, y = 0}
(cuda-gdb) print threadIdx
$2 = {x = 0, y = 0, z = 0}

8. The grid and block dimensions can also be printed:

(cuda-gdb) print gridDim
$3 = {x = 1, y = 1}
(cuda-gdb) print blockDim
$4 = {x = 256, y = 1, z = 1}

9. Advance kernel execution and verify some data:

(cuda-gdb) next
12 array[threadIdx.x] = idata[threadIdx.x];
(cuda-gdb) next
14 array[threadIdx.x] = ((0xf0f0f0f0 & array[threadIdx.x]) >> 4) |
(cuda-gdb) next
16 array[threadIdx.x] = ((0xcccccccc & array[threadIdx.x]) >> 2) |
(cuda-gdb) next
18 array[threadIdx.x] = ((0xaaaaaaaa & array[threadIdx.x]) >> 1) |
(cuda-gdb) next

Breakpoint 3, bitreverse <<<(1,1),(256,1,1)>>> (data=0x100000) at bitreverse.cu:21
21 unsigned int *idata = array[threadIdx.x];
(cuda-gdb) print array[0]@12
Walk-Through Examples

10. Since thread (0,0,0) reverses the value of 0, switch to a different thread to show more interesting data:

(cuda-gdb) cuda thread 170
[Switching focus to CUDA kernel 0, grid 1, block (0,0,0), thread (170,0,0), device 0, sm 0, warp 5, lane 10]

11. Delete the breakpoints and continue the program to completion:

(cuda-gdb) delete breakpoints
Delete all breakpoints? (y or n) y
(cuda-gdb) continue
Continuing.
Program exited normally.

(cuda-gdb)

11.2. Example: autostep

This section shows how to use the autostep command and demonstrates how it helps increase the precision of memory error reporting.

Source Code

```c
#define NUM_BLOCKS 8
#define THREADS_PER_BLOCK 64

__global__ void example(int **data) {
    int value1, value2, value3, value4, value5;
    int idx1, idx2, idx3;

    idx1 = blockIdx.x * blockDim.x;
    idx2 = threadIdx.x;
    idx3 = idx1 + idx2;

    value1 = *(data[idx1]);
    value2 = *(data[idx2]);
    value3 = value1 + value2;
    value4 = value1 * value2;
    value5 = value3 + value4;

    *(data[idx3]) = value5;
    *(data[idx1]) = value3;
    *(data[idx2]) = value4;
    idx1 = idx2 = idx3 = 0;
}

int main(int argc, char *argv[]) {
    int *host_data[NUM_BLOCKS * THREADS_PER_BLOCK];
    int **dev_data;
```
In this small example, we have an array of pointers to integers, and we want to do some operations on the integers. Suppose, however, that one of the pointers is NULL as shown in line 38. This will cause CUDA_EXCEPTION_10 "Device Illegal Address" to be thrown when we try to access the integer that corresponds with block 3, thread 39. This exception should occur at line 16 when we try to write to that value.

### 11.2.1. Debugging with Autosteps

1. Compile the example and start CUDA-GDB as normal. We begin by running the program:

   ```
   (cuda-gdb) run
   Starting program: /home/jitud/cudagdb_test/autostep_ex/example
   [Thread debugging using libthread_db enabled] [New Thread 0x7ffff5688700 (LWP 9083)]
   [Context Create of context 0x617270 on Device 0]
   [Launch of CUDA Kernel 0 (example<<<(8,1,1),(64,1,1)>>>) on Device 0]
   Program received signal CUDA_EXCEPTION_10, Device Illegal Address.
   [Switching focus to CUDA kernel 0, grid 1, block (1,0,0), thread (0,0,0), device 0, sm 1, warp 0, lane 0]
   0x00000000000796f60 in example (data=0x200300000) at example.cu:17
   17        *(data[idx1]) = value3;
   ```

   As expected, we received a CUDA_EXCEPTION_10. However, the reported thread is block 1, thread 0 and the line is 17. Since CUDA_EXCEPTION_10 is a Global error, there is no thread information that is reported, so we would manually have to inspect all 512 threads.

2. Set autosteps. To get more accurate information, we reason that since CUDA_EXCEPTION_10 is a memory access error, it must occur on code that accesses memory. This happens on lines 11, 12, 16, 17, and 18, so we set two autostep windows for those areas:

   ```
   (cuda-gdb) autostep 11 for 2 lines
   Breakpoint 1 at 0x796d18: file example.cu, line 11.
   Created autostep of length 2 lines
   (cuda-gdb) autostep 16 for 3 lines
   ```
3. Finally, we run the program again with these autosteps:

(cuda-gdb) run
The program being debugged has been started already.
Start it from the beginning? (y or n) y
[Termination of CUDA Kernel 0 (example<<<(8,1,1),(64,1,1)>>>) on Device 0]
Starting program: /home/jitud/cudagdb_test/autostep_ex/example
[Thread debugging using libthread_db enabled]
[New Thread 0x7ffffff5688700 (LWP 9089)]
[Context Create of context 0x617270 on Device 0]
[Launch of CUDA Kernel 1 (example<<<(8,1,1),(64,1,1)>>>) on Device 0]
[Switching focus to CUDA kernel 1, grid 1, block (0,0,0), thread (0,0,0),
device 0, sm 0, warp 0, lane 0]

Program received signal CUDA_EXCEPTION_10, Device Illegal Address.
[Current focus set to CUDA kernel 1, grid 1, block (3,0,0), thread (32,0,0),
device 0, sm 1, warp 3, lane 0]
Autostep precisely caught exception at example.cu:16 (0x796e90)

This time we correctly caught the exception at line 16. Even though CUDA_EXCEPTION_10
is a global error, we have now narrowed it down to a warp error, so we now know that the
thread that threw the exception must have been in the same warp as block 3, thread 32.

In this example, we have narrowed down the scope of the error from 512 threads down to 32
threads just by setting two autosteps and re-running the program.

11.3. Example: MPI CUDA Application

For large scale MPI CUDA application debugging, NVIDIA recommends using parallel
debuggers supplied by our partners Allinea and Totalview. Both make excellent parallel
debuggers with extended support for CUDA. However, for debugging smaller applications, or
for debugging just a few processes in a large application, CUDA-GDB can be used.

If the cluster nodes have xterm support, launch CUDA-GDB in the same way you would launch
gdb with your job launcher. For example:

$ mpirun -np 4 -host nv1,nv2 xterm -e cuda-gdb a.out

You may have to export the DISPLAY variable to make sure that the xterm finds its way back to
your display. For example:

$ mpirun -np 4 -host nv1,nv2 -x DISPLAY=host.nvidia.com:0 xterm -e cuda-gdb a.out

Job launchers have different ways of exporting environment variables to the cluster nodes.
Consult your job launcher documentation for more details.

When xterm is not supported by your cluster environment, you can insert a spin loop inside
your program, ssh to the compute node(s), and attach onto the MPI processes. Somewhere
near the start of your program, add a code snippet similar to the following:

```c
int i = 0;
```
Recompile and launch the application. After it starts, ssh to the node(s) of interest and attach to the process using CUDA-GDB. Set the variable \( i \) to 1 to break out of the loop:

```bash
$ mpirun -np 2 -host nv1,nv2 a.out
PID 20060 on node nv1 is ready for attach
PID 5488 on node nv2 is ready for attach
```

```bash
$ ssh nv1
[nv1]$ cuda-gdb --pid 5488
```

```bash
$ ssh nv2
[nv2]$ cuda-gdb --pid 20060
```

For larger applications, you can conditionalize the spin loop based on the MPI rank using the `MPI_Comm_rank` function.

For devices with compute capability below 6.0, the software preemption workaround described in [Multiple Debuggers](#) does not work with MPI applications. For those GPUs, ensure each MPI rank targets a unique GPU.

If `CUDA_VISIBLE_DEVICES` is set, it may cause problems with the GPU selection logic in the MPI application. It may also prevent CUDA IPC working between GPUs on a node.
Chapter 12. Tips and Tricks

This section serves as reference to advanced settings and various tips and tricks users of CUDA-GDB can utilize which are not documented elsewhere.

12.1. Command line arguments

--cuda-use-lockfile

When debugging an application, CUDA-GDB will suspend all the visible CUDA-capable devices. On Maxwell devices [SM 5.0], to avoid any resource conflict, only one CUDA-GDB session is allowed at a time. To enforce this restriction, the --cuda-use-lockfile=1 argument can be provided to prevent two CUDA-GDB processes from running simultaneously.

On Maxwell devices [SM 5.0], if the user desires to debug two applications simultaneously through two separate CUDA-GDB sessions, use the CUDA_VISIBLE_DEVICES environment variable to target unique GPUs for each CUDA-GDB session. This is described in more detail in Multiple Debuggers.

The --cuda-use-lockfile=1 argument cannot be provided when debugging multiple ranks of an MPI application that use separate GPUs for each rank.

--disable-python

CUDA-GDB is built with a dlopen mechanism to initialize libpython. It only supports Python 3 and should work with most supported Linux distributions. Since CUDA-GDB does not link directly against the system installed python libraries, sometimes unforeseen errors can be encountered. If a python error is encountered at startup, the --disable-python command-line option can be used to force CUDA-GDB to skip python initialization.

12.2. set cuda break_on_launch

To break on the first instruction of every launched kernel, set the break_on_launch option to application:

(cuda-gdb) set cuda break_on_launch application
Possible options are:

- **none**
  - no kernel, application or system (default)
- **application**
  - kernel launched by the user application
- **system**
  - any kernel launched by the driver, such as memset
- **all**
  - any kernel, application and system

Those automatic breakpoints are not displayed by the info breakpoints command and are managed separately from individual breakpoints. Turning off the option will not delete other individual breakpoints set to the same address and vice-versa.

### 12.3. set cuda launch_blocking

When enabled, the kernel launches are synchronous as if the environment variable `CUDA_LAUNCH_BLOCKING` had been set to 1. Once blocking, the launches are effectively serialized and may be easier to debug.

- **(cuda-gdb) set cuda launch_blocking off**

  The kernel launches are launched synchronously or asynchronously as dictated by the application. This is the default.

- **(cuda-gdb) set cuda launch_blocking on**

  The kernel launches are synchronous. If the application has already started, the change will only take affect after the current session has terminated.

### 12.4. set cuda notify

Any time a CUDA event occurs, the debugger needs to be notified. The notification takes place in the form of a signal being sent to a host thread. The host thread to receive that special signal is determined with the `set cuda notify` option.

- **(cuda-gdb) set cuda notify youngest**

  The host thread with the smallest thread id will receive the notification signal (default).

- **(cuda-gdb) set cuda notify random**

  An arbitrary host thread will receive the notification signal.
12.5. **set cuda ptx_cache**

Before accessing the value of a variable, the debugger checks whether the variable is live or not at the current PC. On CUDA devices, the variables may not be live all the time and will be reported as "Optimized Out".

CUDA-GDB offers an option to circumvent this limitation by caching the value of the variable at the PTX register level. Each source variable is compiled into a PTX register, which is later mapped to one or more hardware registers. Using the debug information emitted by the compiler, the debugger may be able cache the value of a PTX register based on the latest hardware register it was mapped to at an earlier time.

This optimization is always correct. When enabled, the cached value will be displayed as the normal value read from an actual hardware register and indicated with the (cached) prefix. The optimization will only kick in while single-stepping the code.

- **(cuda-gdb) set cuda ptx_cache off**
  
  The debugger only read the value of live variables.

- **(cuda-gdb) set cuda ptx_cache on**
  
  The debugger will use the cached value when possible. This setting is the default and is always safe.

12.6. **set cuda single_stepping_optimizations**

Single-stepping can take a lot of time. When enabled, this option tells the debugger to use safe tricks to accelerate single-stepping.

- **(cuda-gdb) set cuda single_stepping_optimizations off**
  
  The debugger will not try to accelerate single-stepping. This is the unique and default behavior in the 5.5 release and earlier.

- **(cuda-gdb) set cuda single_stepping_optimizations on**
  
  The debugger will use safe techniques to accelerate single-stepping. This is the default starting with the 6.0 release.

12.7. **set cuda thread_selection**

When the debugger must choose an active thread to focus on, the decision is guided by a heuristics. The set cuda thread_selection guides those heuristics.
12.8. set cuda value_extrapolation

Before accessing the value of a variable, the debugger checks whether the variable is live or not at the current PC. On CUDA devices, the variables may not be live all the time and will be reported as “Optimized Out”.

CUDA-GDB offers an option to opportunistically circumvent this limitation by extrapolating the value of a variable when the debugger would otherwise mark it as optimized out. The extrapolation is not guaranteed to be accurate and must be used carefully. If the register that was used to store the value of a variable has been reused since the last time the variable was seen as live, then the reported value will be wrong. Therefore, any value printed using the option will be marked as "(possibly)".

- (cuda-gdb) set cuda value_extrapolation off

The debugger only read the value of live variables. This setting is the default and is always safe.

- (cuda-gdb) set cuda value_extrapolation on

The debugger will attempt to extrapolate the value of variables beyound their respective live ranges. This setting may report erroneous values.

12.9. Debugging Docker Containers

When debugging an application within a Docker container, the PTRACE capability needs to be enabled. The user needs to also ensure that the root file system has both read/write permissions set.

To enable the PTRACE capability, add the following to your Docker run command:

```
--cap-add=SYS_PTRACE
```

12.10. Switching to Classic Debugger Backend

A new debugger backend named the Unified Debugger (UD) has been introduced on Linux platforms with the CTK 11.8 release. UD allows for a unified debugger backend shared with
debugging tools such as cuda-gdb and NVIDIA® Nsight™ VSE. UD is supported across multiple platforms including both Windows and Linux. The end user experience with UD is transparent to existing tool use.

The previous debugger backend, known as the classic debugger backend, can still be used by setting the `CUDBG_USE_LEGACY_DEBUGGER` to 1 in the environment before starting cuda-gdb.

UD is not supported on Maxwell GPUs. Users must switch to the classic debugger backend to debug their applications on Maxwell GPUs.

### 12.11. Thread Block Clusters

CUDA applications that make use of Thread Block Clusters will see the cluster index displayed in the CUDA focus. Both cluster index and cluster dimension can be queried by printing the convenience variables `clusterIdx` and `clusterDim`.
Appendix A. Supported Platforms

Host Platform Requirements
CUDA-GDB is supported on all the platforms supported by the CUDA toolkit with which it is shipped. See the CUDA Toolkit release notes for more information.

GPU Requirements
Debugging is supported on all CUDA-capable GPUs supported by the current CUDA release.

GDB Python integration
GDB Python integration is supported in cuda-gdb with a dlopen mechanism in order to support multiple python3 interpreters across different platforms. Because of this, cuda-gdb only supports a subset of all python3 interpreters. Support exists for the following Python versions: Python 3.6, Python 3.7, Python 3.8, and Python 3.9

Python can be explicitly disabled via the command-line argument --disable-python, as mentioned in Command line arguments.
Appendix B. Common Issues on Supported Operating Systems

The following are known issues with the current release on supported operating systems and how to fix them.

**Python not initialized**

This happens due to a missing Python 3.x library on the machine, installing it fixes the issue. This can also be caused by having a mismatched major.minor version of libpython installed with the default python3 interpreter in PATH. A libpython version matching the default python3 interpreter in PATH must be available. The libpython version can be determined with the `python3 --version` command. For example, the following command would tell us that a `libpython3.8.so*` needs to be installed in a default library search path:

```
$ python3 --version
Python 3.8.10
```

Specific commands to install the proper libpython are below.

**CentOS/RHEL 7/8**

```
$ sudo yum -y install python3-libs
```

**Debian 10**

```
$ sudo apt-get -y install libpython3-stdlib
```

**Fedora 31**

```
$ sudo yum -y install python3-libs
```

**OpenSUSE 15**

```
$ sudo zypper install -y libpython3
```

**Ubuntu 16.04/18.04/20.04**

```
$ sudo apt-get -y install python3.8
$ sudo apt-get -y install libpython3.8
```
Appendix C. Known Issues

The following are known issues with the current release.

- Setting a breakpoint on a line within a __device__ or __global__ function before its module is loaded may result in the breakpoint being temporarily set on the first line of a function below in the source code. As soon as the module for the targeted function is loaded, the breakpoint will be reset properly. In the meantime, the breakpoint may be hit, depending on the application. In those situations, the breakpoint can be safely ignored, and the application can be resumed.

- The scheduler-locking option cannot be set to on.

- Stepping again after stepping out of a kernel results in undetermined behavior. It is recommended to use the ‘continue’ command instead.

- When remotely debugging 32-bit applications on a 64-bit server, the cuda-gdbserver binary used must be 32-bit.

- Attaching to a CUDA application with Software Preemption enabled in cuda-gdb is not supported.

- Attaching to CUDA application running in MPS client mode is not supported.

- Attaching to the MPS server process (nvidia-cuda-mps-server) using cuda-gdb, or starting the MPS server with cuda-gdb is not supported.

- If a CUDA application is started in the MPS client mode with cuda-gdb, the MPS client will wait until all other MPS clients have terminated, and will then run as non-MPS application.

- On Android and on other systems-on-chip with compute-capable GPU, debugger will always report managed memory as resident on the device.

- Attaching to CUDA application on Android or QNX is not supported.

- Debugging APK binaries is not supported.

- Significant performance degradation will occur when the debugger steps over inlined routines.
Because inlined code blocks may have multiple exit points, under the hood, the debugger steps every single instruction until an exit point is reached, which incurs considerable cost for large routines. The following actions are recommended to avoid this problem:

- Avoid using `__forceinline__` when declaring a function. (For code is compiled with debug information, only routines declared with the `__forceinline__` keyword are actually inlined)

- Use the `until <line#>` command to step over inlined subroutines.

- On Jetson, calls to the cuda API might result in the debugger jumping to `_dl_catch_exception()`. A workaround is to continue.

- On Jetson and Drive devices GPU debugging works correctly only if the debugger is run with the root permissions. Changes to devfs node permissions are required for the debugger to work without running as root.

- Debugger can miss reporting an induced trap(`__trap()`) in case it is the next instruction executed after the device resumes from a breakpoint.

- Debugger can miss reporting breakpoints or exceptions during resume in case new warps are launched on a previously empty SM.

- Debugger uses the libpython installed on the system. Use of Python scripting functionality will expose cuda-gdb to the same vulnerabilities as those in the system libpython version. It is recommended to always keep the system libpython library up-to-date.

- TUI mode is not supported to avoid dependencies on the readline library.

- Windows Subsystem for Linux (WSL) is not supported on Ada and Hopper platforms. Support will be added in a future release.
