Chapter 1.  Introduction

1.1.  nvJPEG Decoder

The nvJPEG library provides high-performance, GPU accelerated JPEG decoding functionality for image formats commonly used in deep learning and hyperscale multimedia applications. The library offers single and batched JPEG decoding capabilities which efficiently utilize the available GPU resources for optimum performance; and the flexibility for users to manage the memory allocation needed for decoding.

The nvJPEG library enables the following functions: use the JPEG image data stream as input; retrieve the width and height of the image from the data stream, and use this retrieved information to manage the GPU memory allocation and the decoding. A dedicated API is provided for retrieving the image information from the raw JPEG image data stream.

Tip: Throughout this document, the terms "CPU" and "Host" are used synonymously. Similarly, the terms "GPU" and "Device" are synonymous.

The nvJPEG library supports the following:

**JPEG options:**

- Baseline and Progressive JPEG decoding/encoding
- 8 bits per pixel
- Huffman bitstream decoding
- Upto 4 channel JPEG bitstreams
- 8- and 16-bit quantization tables
- The following chroma subsampling for the 3 color channels Y, Cb, Cr (Y, U, V):
  - 4:4:4
  - 4:2:2
  - 4:2:0
  - 4:4:0
Features:

- Hybrid decoding using both the CPU (i.e., host) and the GPU (i.e., device).
- Hardware acceleration for baseline JPEG decode on supported platforms.
- Input to the library is in the host memory, and the output is in the GPU memory.
- Single image and batched image decoding.
- Single phase and multiple phases decoding.
- Color space conversion.
- User-provided memory manager for the device and pinned host memory allocations.

1.2. nvJPEG Encoder

The encoding functions of the nvJPEG library perform GPU-accelerated compression of user’s image data to the JPEG bitstream. User can provide input data in a number of formats and color spaces, and control the encoding process with parameters. Encoding functionality will allocate temporary buffers using user-provided memory allocator.

Before calling the encoding functions the user should perform a few prerequisite steps using the helper functions described in nvJPEG Encoder Helper API Reference.

1.3. Thread Safety

Not all nvJPEG types are thread safe.

When using decoder APIs across multiple threads, the following decoder types should be instantiated separately for each thread: nvjpegJpegStream_t, nvjpegJpegState_t, nvjpegBufferDevice_t, nvjpegBufferPinned_t

When using encoder APIs across multiple threads, nvjpegEncoderState_t should be instantiated separately for each thread.

For user-provided allocators (inputs to nvJPEGCreateEx()), the user needs to ensure thread safety.

1.4. Hardware Acceleration

Starting with CUDA 11.0, hardware accelerated JPEG decode is available on GA100.

Platforms which support hardware accelerated JPEG decode:
- Windows
- Linux (x86_64, PowerPC, ARM64)
Chapter 2. JPEG Decoding

2.1. Using JPEG Decoding

The nvJPEG library provides functions for both the decoding of a single image, and batched decoding of multiple images.

2.1.1. Single Image Decoding

For single-image decoding you provide the data size and a pointer to the file data, and the decoded image is placed in the output buffer.

To use the nvJPEG library, start by calling the helper functions for initialization.

1. Create nvJPEG library handle with one of the helper functions `nvjpegCreateSimple()` or `nvjpegCreateEx()`.

2. Create JPEG state with the helper function `nvjpegJpegStateCreate()`. See `nvJPEG Type Declarations` and `nvjpegJpegStateCreate()`.

The following helper functions are available in the nvJPEG library:

- `nvjpegStatus_t nvjpegGetProperty(libraryPropertyType type, int *value);`
- `[DEPRECATED] nvjpegStatus_t nvjpegCreate(nvjpegBackend_t backend, nvjpegHandle_t *handle, nvjpeg_dev_allocator allocator);`
- `nvjpegStatus_t nvjpegCreateSimple(nvjpegHandle_t *handle);`
- `nvjpegStatus_t nvjpegCreateEx(nvjpegBackend_t backend, nvjpegDevAllocator_t *dev_allocator, nvjpegPinnedAllocator_t *pinned_allocator, unsigned int flags, nvjpegHandle_t *handle);`
- `nvjpegStatus_t nvjpegDestroy(nvjpegHandle_t handle);`
- `nvjpegStatus_t nvjpegJpegStateCreate(nvjpegHandle_t handle, nvjpegJpegState_t *jpeg_handle);`
- `nvjpegStatus_t nvjpegJpegStateDestroy(nvjpegJpegState handle);`
Other helper functions such as \texttt{nvjpegSet*()} and \texttt{nvjpegGet*()} can be used to configure the library functionality on per-handle basis. Refer to the \texttt{helper API reference} for more details.

3. Retrieve the width and height information from the JPEG-encoded image by using the \texttt{nvjpegGetImageInfo()} function.

Below is the signature of \texttt{nvjpegGetImageInfo()} function:

\begin{verbatim}
nvjpegStatus_t nvjpegGetImageInfo(
    nvjpegHandle_t              handle,
    const unsigned char         *data,
    size_t                      length,
    int                         *nComponents,
    nvjpegChromaSubsampling_t   *subsampling,
    int                         *widths,
    int                         *heights);
\end{verbatim}

For each image to be decoded, pass the JPEG data pointer and data length to the above function. The \texttt{nvjpegGetImageInfo()} function is thread safe.

4. One of the outputs of the above \texttt{nvjpegGetImageInfo()} function is \texttt{nvjpegChromaSubsampling_t}. This parameter is an enum type, and its enumerator list is composed of the chroma subsampling property retrieved from the JPEG image. See \texttt{nvJPEG Chroma Subsampling}.

5. Use the \texttt{nvjpegDecode()} function in the \texttt{nvJPEG} library to decode this single JPEG image. See the signature of this function below:

\begin{verbatim}
nvjpegStatus_t nvjpegDecode(
    nvjpegHandle_t          handle,
    nvjpegJpegState_t       jpeg_handle,
    const unsigned char     *data,
    size_t                  length,
    nvjpegOutputFormat_t    output_format,
    nvjpegImage_t           *destination,
    cudaStream_t            stream);
\end{verbatim}

In the above \texttt{nvjpegDecode()} function, the parameters \texttt{nvjpegOutputFormat_t}, \texttt{nvjpegImage_t}, and \texttt{cudaStream_t} can be used to set the output behavior of the \texttt{nvjpegDecode()} function. You provide the \texttt{cudaStream_t} parameter to indicate the stream to which your asynchronous tasks are submitted.

6. The \texttt{nvjpegOutputFormat_t} parameter:

The \texttt{nvjpegOutputFormat_t} parameter can be set to one of the \texttt{output_format} settings below:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{output\_format} & \textbf{Meaning} \\
\hline
\texttt{NVJPEG\_OUTPUT\_UNCHANGED} & Return the decoded image planar format. \\
\hline
\texttt{NVJPEG\_OUTPUT\_RGB} & Convert to planar RGB. \\
\hline
\texttt{NVJPEG\_OUTPUT\_BGR} & Convert to planar BGR. \\
\hline
\texttt{NVJPEG\_OUTPUT\_RGBI} & Convert to interleaved RGB. \\
\hline
\texttt{NVJPEG\_OUTPUT\_BGRI} & Convert to interleaved BGR. \\
\hline
\end{tabular}
\end{table}
For example, if the output_format is set to NVJPEG_OUTPUT_Y or NVJPEG_OUTPUT_RGB, or NVJPEG_OUTPUT_BGRI then the output is written only to channel[0], and the other channels are not touched.

Alternately, in the case of planar output, the data is written to the corresponding channels of the nvjpegImage_t destination structure.

Finally, in the case of grayscale JPEG and RGB output, the luminance is used to create the grayscale RGB.

The below table explains the combinations of the output formats and the number of channels supported by the library.

<table>
<thead>
<tr>
<th>No of Channels in bitstream</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output Format</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_UNCHANGED</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_YUV</td>
<td>Only the first channel of the output is populated</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_Y</td>
<td>Yes</td>
<td>No</td>
<td>Yes</td>
<td>Yes[a]</td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_RGB</td>
<td>Yes[b]</td>
<td>No</td>
<td>Yes</td>
<td>Yes[a]</td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_BGR</td>
<td>Yes[b]</td>
<td>No</td>
<td>Yes</td>
<td>Yes[a]</td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_RGBA</td>
<td>Yes[b]</td>
<td>No</td>
<td>Yes</td>
<td>Yes[a]</td>
</tr>
</tbody>
</table>

NOTES:

a. [a] Must be enabled using nvjpegDecodeParamsSetAllowCMYK().

b. [b] Luminance is used to create the grayscale RGB.

7. As mentioned above, an important benefit of the nvjpegGetImageInfo() function is the ability to utilize the image information retrieved from the the input JPEG image to allocate proper GPU memory for your decoding operation.

The nvjpegGetImageInfo() function returns the widths, heights and nComponents parameters.

```c
nvjpegStatus_t nvjpegGetImageInfo(
    nvjpegHandle_t handle,
    const unsigned char *data,
    size_t length,
    int *nComponents,
    int *subsampling,
    int *widths,
    int *heights);
```

You can use the retrieved parameters, widths, heights and nComponents, to calculate the required size for the output buffers, either for a single decoded JPEG, or for every decoded JPEG in a batch.
To optimally set the destination parameter for the `nvjpegDecode()` function, use the following guidelines:

<table>
<thead>
<tr>
<th>For the output_format:</th>
<th><code>destination.pitch[0]</code> should be at least: <code>width[0]</code></th>
<th><code>destination.channel[0]</code> should be at least of size: <code>destination.pitch[0]*height[0]</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_OUTPUT_Y</td>
<td><code>destination.pitch[0]</code> should be at least: <code>width[0]</code></td>
<td><code>destination.channel[0]</code> should be at least of size: <code>destination.pitch[0]*height[0]</code></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_YUV</td>
<td><code>destination.pitch[c]</code> should be at least: <code>width[c]</code> for <code>c = 0, 1, 2</code></td>
<td><code>destination.channel[c]</code> should be at least of size: <code>destination.pitch[c]*height[c]</code> for <code>c = 0, 1, 2</code></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_RGB and</td>
<td><code>width[0]</code> for <code>c = 0, 1, 2</code></td>
<td><code>destination.pitch[0]*height[0]</code> for <code>c = 0, 1, 2</code></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_BGR</td>
<td><code>width[0]</code> for <code>c = 0, 1, 2</code></td>
<td><code>destination.pitch[0]*height[0]</code> for <code>c = 0, 1, 2</code></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_RGBI and</td>
<td><code>width[0]*3</code></td>
<td><code>destination.pitch[0]*height[0]</code></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_BGRI</td>
<td><code>width[0]*3</code></td>
<td><code>destination.pitch[0]*height[0]</code></td>
</tr>
<tr>
<td>NVJPEG_OUTPUT_UNCHANGED</td>
<td><code>destination.pitch[c]*height[c]</code> for <code>c = [ 0, nComponents - 1 ]</code></td>
<td><code>destination.pitch[c]*height[c]</code> for <code>c = [ 0, nComponents - 1 ]</code></td>
</tr>
</tbody>
</table>

8. Ensure that the `nvjpegImage_t` structure (or structures, in the case of batched decode) is filled with the pointers and pitches of allocated buffers. The `nvjpegImage_t` structure that holds the output pointers is defined as follows:

```c
typedef struct
{
    unsigned char * channel[NVJPEG_MAX_COMPONENT];
    size_t pitch[NVJPEG_MAX_COMPONENT];
} nvjpegImage_t;
```

`NVJPEG_MAX_COMPONENT` is the maximum number of color components the `nvJPEG` library supports in the current release. For generic images, this is the maximum number of encoded channels that the library is able to decompress.

9. Finally, when you call the `nvjpegDecode()` function with the parameters as described above, the `nvjpegDecode()` function fills the output buffers with the decoded data.

### 2.1.2. Decode using Decoupled Phases

The `nvJPEG` library allows further separation of the host and device phases of the decode process. The host phase of the decoding will not need to access to device resources.

A few examples of decoupled APIs can be found under [Decode API - Decoupled Decoding](#).

Below is the sequence of API calls to decode a single image:

1. Initialize all the items that are used in the decoding process:
   a). Create the library handle using one of the library handle initialization routines.
   b). Choose decoder implementation `nvjpegBackend_t`, and create decoder using `nvjpegDecoderCreate()`.
   c). Create JPEG decoder state using `nvjpegDecoderStateCreate()`.
   d). Create JPEG stream using `nvjpegJpegStreamCreate()`.
e). Create the pinned and device buffers used by the decoder using the below APIs respectively. These buffers are used to store intermediate decoding results.

- `nvjpegBufferPinnedCreate()`
- `nvjpegBufferDeviceCreate()`

f). Link the buffers to the JPEG state using the following APIs respectively:

- `nvjpegStateAttachPinnedBuffer()`
- `nvjpegStateAttachDeviceBuffer()`

g). Create decode parameters using the below API. This is used to set the output format, and enable ROI decode:

- `nvjpegDecodeParamsCreate()`

2. Perform decoding:

a). Parse the jpeg bit-stream using `nvjpegJpegStreamParse()`

- Encoded bitstream information, like channel dimensions, can be retrieved using the below API. This information is used to allocate the output pointers in `nvjpegImage_t`.
  - `nvjpegJpegStreamGetComponentsNum()`
  - `nvjpegJpegStreamGetComponentDimensions()`

b). Call the decode API in the below sequence to decode the image:

- `nvjpegDecodeJpegHost()`
- `nvjpegDecodeJpegTransferToDevice()`
- `nvjpegDecodeJpegDevice()`

**2.1.3. Batched Image Decoding**

For the batched image decoding you provide pointers to multiple file data in the memory, and also provide the buffer sizes for each file data. The nvJPEG library will decode these multiple images, and will place the decoded data in the output buffers that you specified in the parameters.

**2.1.3.1. Single Phase**

For batched image decoding in single phase, follow these steps:

1. Call `nvjpegDecodeBatchedInitialize()` function to initialize the batched decoder. Specify the batch size in the `batch_size` parameter. See `nvjpegDecodeBatchedInitialize()`.

2. Next, call `nvjpegDecodeBatched()` for each new batch. Make sure to pass the parameters that are correct to the specific batch of images. If the size of the batch...
changes, or if the batch decoding fails, then call the \texttt{nvjpegDecodeBatchedInitialize()} function again.

2.2. \textbf{nvJPEG Type Declarations}

2.2.1. \textbf{nvJPEG Backend}

\begin{verbatim}
typedef enum {
    NVJPEG_BACKEND_DEFAULT = 0,
    NVJPEG_BACKEND_HYBRID = 1,
    NVJPEG_BACKEND_GPU_HYBRID = 2,
    NVJPEG_BACKEND_HARDWARE = 3,
    NVJPEG_BACKEND_GPU_HYBRID_DEVICE = 4,
    NVJPEG_BACKEND_HARDWARE_DEVICE = 5
} nvjpegBackend_t;
\end{verbatim}

The \texttt{nvjpegBackend_t} enum is used to select either default back-end by default, or use GPU decoding for baseline JPEG images, or use CPU for Huffman decoding.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_BACKEND_DEFAULT</td>
<td>Back-end is selected internally</td>
</tr>
<tr>
<td>NVJPEG_BACKEND_HYBRID</td>
<td>Uses CPU for Huffman decoding</td>
</tr>
<tr>
<td>NVJPEG_BACKEND_GPU_HYBRID</td>
<td>Uses GPU for Huffman decoding. \texttt{nvjpegDecodeBatched} will use GPU decoding for baseline JPEG images with interleaved scan when batch size is greater than 100. The \texttt{decoupled APIs} will use GPU assisted Huffman decoding.</td>
</tr>
<tr>
<td>NVJPEG_BACKEND_HARDWARE</td>
<td>Uses \texttt{Hardware Acceleration} for decode. Supports baseline JPEG images with single scan with 1 or 3 channels. 410 and 411 chroma subsamplings are not supported.</td>
</tr>
<tr>
<td>NVJPEG_BACKEND_GPU_HYBRID_DEVICE</td>
<td>Supports input bitstream on device memory. Can be used only with batched decode APIs for baseline JPEG images without restart intervals.</td>
</tr>
<tr>
<td>NVJPEG_BACKEND_HARDWARE_DEVICE</td>
<td>Supports input bitstream on device memory. Can be used only with batched decode APIs. Uses \texttt{Hardware Acceleration} for decode. Supports baseline JPEG images with single scan with 1 or 3 channels. 410 and 411 chroma subsamplings are not supported.</td>
</tr>
</tbody>
</table>

2.2.2. \textbf{nvJPEG Bitstream Handle}

\begin{verbatim}
struct nvjpegJpegStream;
typedef struct nvjpegJpegStream* nvjpegJpegStream_t;
\end{verbatim}

This handle stores the bit-stream parameters on the host. This helps retrieve bitstream metadata using APIs defined in \texttt{nvJPEG Stream API}. 

\texttt{nvJPEG}
2.2.3.  nvJPEG Decode Device Buffer Handle

```c
struct nvjpegBufferDevice;
typedef struct nvjpegBufferDevice* nvjpegBufferDevice_t;
```

This `nvjpegBufferDevice_t` is used by decoder states to store the intermediate information in device memory.

2.2.4.  nvJPEG Decode Parameter Handle

```c
struct nvjpegDecodeParams;
typedef struct nvjpegDecodeParams* nvjpegDecodeParams_t;
```

This decoder parameter handle stores the parameters like output format, and the ROI decode parameters that are set using APIs defined in [nvJPEG Chroma Subsampling](#).

2.2.5.  nvJPEG Decode Pinned Buffer Handle

```c
struct nvjpegBufferPinned;
typedef struct nvjpegBufferPinned* nvjpegBufferPinned_t;
```

This `nvjpegBufferPinned_t` handle is used by decoder states to store the intermediate information on pinned memory.

2.2.6.  nvJPEG Decoder Handle

```c
struct nvjpegJpegDecoder;
typedef struct nvjpegJpegDecoder* nvjpegJpegDecoder_t;
```

This decoder handle stores the intermediate decoder data, which is shared across the decoding stages. This decoder handle is initialized for a given `nvjpegBackend_t`. It is used as input to the [Decode API—Decoupled Decoding](#).

2.2.7.  nvJPEG Host Pinned Memory Allocator Interface

```c
typedef int (*tPinnedMalloc)(void**, size_t, unsigned int flags);
typedef int (*tPinnedFree)(void*);
typedef struct {
    tPinnedMalloc pinned_malloc;
    tPinnedFree pinned_free;
} nvjpegPinnedAllocator_t;
```

When the `nvjpegPinnedAllocator_t *allocator` parameter in the `nvjpegCreateEx()` function is set as a pointer to the above `nvjpegPinnedAllocator_t` structure, then this structure will be used for allocating and releasing host pinned memory for copying data to/from device. The function prototypes for the memory allocation and memory freeing functions are similar to the `cudaHostAlloc()` and `cudaFreeHost()` functions. They will return 0 in case of success, and non-zero otherwise.
However, if the `nvjpegPinnedAllocator_t *allocator` parameter in the `nvjpegCreateEx()` function is set to NULL, then the default memory allocation functions `cudaHostAlloc()` and `cudaFreeHost()` will be used. When using `nvjpegCreate()` or `nvjpegCreateSimple()` function to create library handle, the default host pinned memory allocator will be used.

### 2.2.8. nvJPEG Image

```c
typedef struct {
    unsigned char * channel[NVJPEG_MAX_COMPONENT];
    size_t pitch[NVJPEG_MAX_COMPONENT];
} nvjpegImage_t;
```

The `nvjpegImage_t` structure (or structures, in the case of batched decode) is used to fill with the pointers and pitches of allocated buffers. The `nvjpegImage_t` structure that holds the output pointers.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_MAX_COMPONENT</td>
<td>Maximum number of color components the nvJPEG library supports. For generic images, this is the maximum number of encoded channels that the library is able to decompress.</td>
</tr>
</tbody>
</table>

### 2.2.9. nvJPEG Device Memory Allocator Interface

```c
typedef int (*tDevMalloc)(void**, size_t);
typedef int (*tDevFree)(void*);
typedef struct {
    tDevMalloc dev_malloc;
    tDevFree dev_free;
} nvjpegDevAllocator_t;
```

Users can tell the library to use their own device memory allocator. The function prototypes for the memory allocation and memory freeing functions are similar to the `cudaMalloc()` and `cudaFree()` functions. They should return 0 in case of success, and non-zero otherwise.

A pointer to the `nvjpegDevAllocator_t` structure, with properly filled fields, should be provided to the `nvjpegCreate()` function. NULL is accepted, in which case the default memory allocation functions `cudaMalloc()` and `cudaFree()` is used.

When the `nvjpegDevAllocator_t *allocator` parameter in the `nvjpegCreate()` or `nvjpegCreateEx()` function is set as a pointer to the above `nvjpegDevAllocator_t` structure, then this structure is used for allocating and releasing the device memory. The function prototypes for the memory allocation and memory freeing functions are similar to the `cudaMalloc()` and `cudaFree()` functions. They should return 0 in case of success, and non-zero otherwise.

However, if the `nvjpegDevAllocator_t *allocator` parameter in the `nvjpegCreate()` or `nvjpegCreateEx()` function is set to NULL, then the default memory allocation functions `cudaMalloc()` and `cudaFree()` will be used. When using `nvjpegCreateSimple()` function to create library handle the default device memory allocator will be used.
### 2.2.10. nvJPEG Opaque JPEG Decoding State Handle

```c
struct nvjpegJpegState;
typedef struct nvjpegJpegState* nvjpegJpegState_t;
```

The `nvjpegJpegState` structure stores the temporary JPEG information. It should be initialized before any usage. This JPEG state handle can be reused after being used in another decoding. The same JPEG handle should be used across the decoding phases for the same image or batch. Multiple threads are allowed to share the JPEG state handle only when processing same batch during first phase (nvjpegDecodePhaseOne).

### 2.2.11. nvJPEG Opaque Library Handle Struct

```c
struct nvjpegHandle;
typedef struct nvjpegHandle* nvjpegHandle_t;
```

The library handle is used in any consecutive nvJPEG library calls, and should be initialized first.

The library handle is thread safe, and can be used by multiple threads simultaneously.

### 2.2.12. nvJPEG Output Pointer Struct

```c
typedef struct {
    unsigned char * channel[NVJPEG_MAX_COMPONENT];
    size_t     pitch[NVJPEG_MAX_COMPONENT];
} nvjpegImage_t;
```

The `nvjpegImage_t` struct holds the pointers to the output buffers, and holds the corresponding strides of those buffers for the image decoding.

See [Single Image Decoding](#) on how to set up the `nvjpegImage_t` struct.

### 2.2.13. nvJPEG Jpeg Encoding

```c
typedef enum {
    NVJPEG_ENCODING_UNKNOWN                      = 0x0,
    NVJPEG_ENCODING_BASELINE_DCT                 = 0xc0,
    NVJPEG_ENCODING_EXTENDED_SEQUENTIAL_DCT_HUFFMAN = 0xc1,
    NVJPEG_ENCODING_PROGRESSIVE_DCT_HUFFMAN      = 0xc2
} nvjpegJpegEncoding_t;
```

The `nvjpegJpegEncoding_t` enum lists the JPEG encoding types that are supported by the nvJPEG library. The enum values are based on the markers defined in the JPEG specification.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_ENCODING_UNKNOWN</td>
<td>This value is returned for all the JPEG markers not supported by the nvJPEG library.</td>
</tr>
<tr>
<td>NVJPEG_ENCODING_BASELINE_DCT</td>
<td>Corresponds to the JPEG marker 0xc0, refer to the JPEG spec for more details.</td>
</tr>
</tbody>
</table>
### 2.2.14. nvJPEG Scale Factor

```c
typedef enum {
    NVJPEG_SCALE_NONE = 0,
    NVJPEG_SCALE_1_BY_2 = 1,
    NVJPEG_SCALE_1_BY_4 = 2,
    NVJPEG_SCALE_1_BY_8 = 3
} nvjpegScaleFactor_t;
```

The `nvjpegScaleFactor_t` enum lists all the scale factors supported by the library. This feature is supported when `nvjpeg` handles are instantiated using `NVJPEG_BACKEND_HARDWARE`.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_SCALE_NONE</td>
<td>Decoded output is not scaled</td>
</tr>
<tr>
<td>NVJPEG_SCALE_1_BY_2</td>
<td>Decoded output width and height are scaled by a factor of 1/2</td>
</tr>
<tr>
<td>NVJPEG_SCALE_1_BY_4</td>
<td>Decoded output width and height are scaled by a factor of 1/4</td>
</tr>
<tr>
<td>NVJPEG_SCALE_1_BY_8</td>
<td>Decoded output width and height are scaled by a factor of 1/8</td>
</tr>
</tbody>
</table>

### 2.2.15. nvJPEG Flags

```c
#define NVJPEG_FLAGS_DEFAULT 0
#define NVJPEG_FLAGS_HW_DECODE_NO_PIPELINE 1
#define NVJPEG_FLAGS_ENABLE_MEMORY_POOLS   2
#define NVJPEG_FLAGS_BITSTREAM_STRICT      4
```

`nvJPEG` flags provide additional controls when initializing the library using `nvJPEGCreateEx()`. It is possible to combine the flags as they are bit fields.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_FLAGS_DEFAULT</td>
<td>Corresponds to default library behavior</td>
</tr>
<tr>
<td>NVJPEG_FLAGS_HW_DECODE_NO_PIPELINE</td>
<td>To be used when the library is initialized with <code>NVJPEG_BACKEND_HARDWARE</code>. It will be ignored for other back-ends. <code>nvjpeg</code> in batched decode mode buffers additional images to achieve optimal performance. Use this flag to disable buffering of additional images.</td>
</tr>
<tr>
<td>NVJPEG_FLAGS_ENABLE_MEMORY_POOLS [Deprecated]</td>
<td>Starting with CUDA 11.1 this flag will be ignored</td>
</tr>
</tbody>
</table>
JPEG Decoding

**2.2.16. nvJPEG Exif Orientation**

```c
typedef enum {
    NVJPEG_ORIENTATION_UNKNOWN = 0,
    NVJPEG_ORIENTATION_NORMAL = 1,
    NVJPEG_ORIENTATION_FLIP_HORIZONTAL = 2,
    NVJPEG_ORIENTATION_ROTATE_180 = 3,
    NVJPEG_ORIENTATION_FLIP_VERTICAL = 4,
    NVJPEG_ORIENTATION_TRANSPOSE = 5,
    NVJPEG_ORIENTATION_ROTATE_90 = 6,
    NVJPEG_ORIENTATION_TRANSVERSE = 7,
    NVJPEG_ORIENTATION_ROTATE_270 = 8
} nvjpegExifOrientation_t;
```

The `nvjpegExifOrientation_t` enum represents the exif orientation in a jfif/jpeg file. Exif orientation information is typically used to denote the digital camera sensor orientation at the time of image capture.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_ORIENTATION_UNKNOWN</td>
<td>Exif orientation information is not available in the bitstream.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_NORMAL</td>
<td>Decode output remains unchanged.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_FLIP_HORIZONTAL</td>
<td>Decoded output should be mirrored/flipped horizontally.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_ROTATE_180</td>
<td>Decoded output should be rotated 180 degrees.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_FLIP_VERTICAL</td>
<td>Decoded output should be mirrored/flipped vertically.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_TRANSPOSE</td>
<td>Decoded output should be flipped/mirrored horizontally followed by a 90 degrees counter-clockwise rotation</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_ROTATE_90</td>
<td>Decoded output should be rotated 90 degrees counter-clockwise.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_TRANSVERSE</td>
<td>Decoded output should be flipped/mirrored horizontally followed by a 270 degrees counter-clockwise rotation.</td>
</tr>
<tr>
<td>NVJPEG_ORIENTATION_ROTATE_270</td>
<td>Decoded output should be rotated 270 degrees counter-clockwise.</td>
</tr>
</tbody>
</table>

**2.3. nvJPEG API Reference**

This section describes the nvJPEG decoder API.
2.3.1. nvJPEG Helper API Reference

2.3.1.1. nvjpegGetProperty()

Gets the numeric value for the major or minor version, or the patch level, of the nvJPEG library.

Signature:

```c
nvjpegStatus_t nvjpegGetProperty(
    libraryPropertyType type,
    int *value);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libraryPropertyType type</td>
<td>Input</td>
<td>Host</td>
<td>One of the supported libraryPropertyType values, that is, MAJOR_VERSION, MINOR_VERSION or PATCH_LEVEL.</td>
</tr>
<tr>
<td>int *value</td>
<td>Output</td>
<td>Host</td>
<td>The numeric value corresponding to the specific libraryPropertyType requested.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.1.2. nvjpegGetCudartProperty()

Gets the numeric value for the major version, minor version, or the patch level of the CUDA toolkit that was used to build nvJPEG library. For the same information on the nvJPEG library itself, see nvjpegGetProperty().

Signature:

```c
nvjpegStatus_t nvjpegGetCudartProperty(
    libraryPropertyType type,
    int *value);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>libraryPropertyType type</td>
<td>Input</td>
<td>Host</td>
<td>One of the supported libraryPropertyType values, that is, MAJOR_VERSION, MINOR_VERSION or PATCH_LEVEL.</td>
</tr>
<tr>
<td>int *value</td>
<td>Output</td>
<td>Host</td>
<td>The numeric value corresponding to the specific libraryPropertyType requested.</td>
</tr>
</tbody>
</table>
Returns:

nvjpegStatus_t — An error code as specified in `nvJPEG API Return Codes`.

### 2.3.1.3. nvjpegCreate() [DEPRECATED]

Allocates and initializes the library handle.

**Note:** This function is deprecated. Use either `nvjpegCreateSimple()` or `nvjpegCreateEx()` functions to create the library handle.

**Signature:**

```
nvjpegStatus_t nvjpegCreate(
    nvjpegBackend_t   backend,
    nvjpegDevAllocator_t   *allocator,
    nvjpegHandle_t   *handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegBackend_t backend</td>
<td>Input</td>
<td>Host</td>
<td>Backend parameter for <code>nvjpegDecodeBatched()</code> API. If this is set to DEFAULT then it automatically chooses one of the underlying algorithms.</td>
</tr>
<tr>
<td>nvjpegDevAllocator_t *allocator</td>
<td>Input</td>
<td>Host</td>
<td>Device memory allocator. See <code>nvjpegDevAllocator_t</code> structure description. If NULL is provided, then the default CUDA runtime <code>cudaMalloc()</code> and <code>cudaFree()</code> functions will be used.</td>
</tr>
<tr>
<td>nvjpegHandle_t *handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>

The `nvjpegBackend_t` parameter is an enum type, with the below enumerated list values:

```
typedef enum {
    NVJPEG_BACKEND_DEFAULT = 0,
    NVJPEG_BACKEND_HYBRID = 1,
} nvjpegBackend_t;
```

**Returns:**

nvjpegStatus_t - An error code as specified in `nvJPEG API Return Codes`.

### 2.3.1.4. nvjpegCreateSimple()

Allocates and initializes the library handle, with default codec implementations selected by library and default memory allocators.
Signature:

```
nvjpegStatus_t nvjpegCreateSimple(nvjpegHandle_t *handle);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t *handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>

Returns:

`nvjpegStatus_t` - An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.1.5. `nvjpegCreateEx()`

Allocates and initializes the library handle using the provided arguments.

Signature:

```
nvjpegStatus_t nvjpegCreateEx(nvjpegBackend_t backend,
   nvjpegDevAllocator_t *dev_allocator,
   nvjpegPinnedAllocator_t *pinned_allocator,
   unsigned int flags,
   nvjpegHandle_t *handle);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegBackend_t backend</td>
<td>Input</td>
<td>Host</td>
<td>Backend parameter for <code>nvjpegDecodeBatched()</code> API. If this is set to DEFAULT</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>then it automatically chooses one of the underlying algorithms.</td>
</tr>
<tr>
<td>nvjpegDevAllocator_t *devAllocator</td>
<td>Input</td>
<td>Host</td>
<td>Device memory allocator. See <code>nvjpegDevAllocator_t</code> structure description. If NULL is provided, then the default CUDA runtime functions <code>cudaMalloc()</code> and <code>cudaFree()</code> will be used.</td>
</tr>
<tr>
<td>nvjpegPinnedAllocator_t *pinned_allocator</td>
<td>Input</td>
<td>Host</td>
<td>Pinned host memory allocator. See <code>nvjpegPinnedAllocator_t</code> structure description. If NULL is provided, then the default CUDA runtime functions <code>cudaHostAlloc()</code> and <code>cudaFreeHost()</code> will be used.</td>
</tr>
<tr>
<td>unsigned int flags</td>
<td>Input</td>
<td>Host</td>
<td>Refer to <a href="#">nvJPEG Flags</a> for details</td>
</tr>
<tr>
<td>nvjpegHandle_t *handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>

Returns:

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).
2.3.1.6. **nvjpegDestroy()**

Releases the library handle.

**Signature:**

```
nvjpegStatus_t nvjpegDestroy(nvjpegHandle_t handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle to release.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t - An error code as specified in [nvJPEG API Return Codes](#).

2.3.1.7. **nvjpegSetDeviceMemoryPadding()**

Use the provided padding for all device memory allocations with specified library handle. A large number will help to amortize the need for device memory reallocations when needed.

**Signature:**

```
nvjpegStatus_t nvjpegSetDeviceMemoryPadding(
    size_t padding,
    nvjpegHandle_t handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size_t padding</td>
<td>Input</td>
<td>Host</td>
<td>Device memory padding to use for all further device memory allocations.</td>
</tr>
<tr>
<td>nvjpegHandle_t *handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t - An error code as specified in [nvJPEG API Return Codes](#).

2.3.1.8. **nvjpegGetDeviceMemoryPadding()**

Retrieve the device memory padding that is currently used for the specified library handle.

**Signature:**

```
nvjpegStatus_t nvjpegGetDeviceMemoryPadding(
    size_t *padding,
    nvjpegHandle_t handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size_t *padding</td>
<td>Input</td>
<td>Host</td>
<td></td>
</tr>
<tr>
<td>nvjpegHandle_t *handle</td>
<td>Input/Output</td>
<td>Host</td>
<td></td>
</tr>
</tbody>
</table>
size_t *padding | Output  | Host  | Device memory padding that is currently used for device memory allocations.
---|---|---|---
nvjpegHandle_t *handle | Input/Output | Host | The library handle.

Returns:

nvjpegStatus_t - An error code as specified in *nvJPEG API Return Codes*.

### 2.3.1.9. nvjpegSetPinnedMemoryPadding()

Use the provided padding for all pinned host memory allocations with specified library handle. A large number will help to amortize the need for pinned host memory reallocations when needed.

**Signature:**

```c
nvjpegStatus_t nvjpegSetPinnedMemoryPadding(
    size_t padding,
    nvjpegHandle_t handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size_t padding</td>
<td>Input</td>
<td>Host</td>
<td>Pinned host memory padding to use for all further pinned host memory allocations.</td>
</tr>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in *nvJPEG API Return Codes*.

### 2.3.1.10. nvjpegGetPinnedMemoryPadding()

Retrieve the pinned host memory padding that is currently used for specified library handle.

**Signature:**

```c
nvjpegStatus_t nvjpegGetPinnedMemoryPadding(
    size_t *padding,
    nvjpegHandle_t handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size_t *padding</td>
<td>Output</td>
<td>Host</td>
<td>Pinned host memory padding that is currently used for pinned host memory allocations.</td>
</tr>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in *nvJPEG API Return Codes*.
2.3.1.11. nvjpegJpegStateCreate()

Allocates and initializes the internal structure required for the JPEG processing.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStateCreate(
   nvjpegHandle_t      handle,
   nvjpegJpegState_t   *jpeg_handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t *jpeg_handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The image state handle.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

2.3.1.12. nvjpegJpegStateDestroy()

Releases the image internal structure.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStateDestroy(nvjpegJpegState handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegState handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>The image state handle.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

2.3.1.13. nvjpegDecoderCreate()

Creates a decoder handle.

**Signature:**

```c
nvjpegStatus_t nvjpegDecoderCreate(
   nvjpegHandle_t nvjpeg_handle,
   nvjpegBackend_t implementation,
   nvjpegJpegDecoder_t* decoder_handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t nvjpeg_handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
</tbody>
</table>
nvjpegBackend_t backend | Input | Host | Backend parameter for the decoder_handle. The back end applies to all the functions under the decoupled API, when called with this handle.

nvjpegJpegDecoder_t decoder_handle | Input/Output | Host | Decoder state handle.

Returns:

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.1.14. nvjpegDecoderDestroy()

Destroys the decoder handle.

**Signature:**

```c
nvjpegStatus_t nvjpegDecoderDestroy(
    nvjpegJpegDecoder_t decoder_handle);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegDecoder_t decoder_handle</td>
<td>Input/Output</td>
<td>Host</td>
<td>Decoder handle.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.1.15. nvjpegDecoderJpegSupported()

Determines whether the decoder_handle is able to handle the bit-stream stored in jpeg_stream.

**Signature:**

```c
nvjpegStatus_t nvjpegDecoderJpegSupported(
    nvjpegJpegDecoder_t decoder_handle,
    nvjpegJpegStream_t jpeg_stream,
    nvjpegDecodeParams_t decode_params,
    int* is_supported);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegDecoder_t decoder_handle</td>
<td>Input</td>
<td>Host</td>
<td>Decoder state handle</td>
</tr>
<tr>
<td>nvjpegJpegStream_t jpeg_stream</td>
<td>Input</td>
<td>Host</td>
<td>Bit stream meta-data</td>
</tr>
<tr>
<td>nvjpegDecodeParams_t decode_params</td>
<td>Input</td>
<td>Host</td>
<td>Decoder output configuration</td>
</tr>
</tbody>
</table>
int* is_supported | Output | Host | Return value of 0 indicates bitstream can be decoded by the decoder_handle, non zero value indicates that the bitstream is not supported

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.1.16. nvjpegDecoderStateCreate()

Creates the decoder_state internal structure. The decoder_state is associated with the nvjpegBackend_t implementation that was used to create the decoder_handle.

Signature:

```
nvjpegStatus_t nvjpegDecoderStateCreate(  
nvjpegHandle_t nvjpeg_handle,  
nvjpegJpegDecoder_t decoder_handle,  
nvjpegJpegState_t* decoder_state);```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t nvjpeg_handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>nvjpegJpegDecoder_t decoder_handle</td>
<td>Input</td>
<td>Host</td>
<td>Decoder handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t* decoder_state</td>
<td>Input/Output</td>
<td>Host</td>
<td>nvJPEG Image State Handle.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.1.17. nvjpegJpegStreamCreate()

Creates jpeg_stream that is used to parse the JPEG bitstream and store bitstream parameters.

Signature:

```
nvjpegStatus_t nvjpegJpegStreamCreate(  
nvjpegHandle_t handle,  
nvjpegJpegStream_t *jpeg_stream);```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle</td>
</tr>
<tr>
<td>nvjpegJpegStream_t *jpeg_stream</td>
<td>Input</td>
<td>Host</td>
<td>Bitstream handle</td>
</tr>
</tbody>
</table>
**Returns:**
nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.1.18. nvjpegJpegStreamDestroy()

Destroys the jpeg_stream structure.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStreamDestroy(
    nvjpegJpegStream_t *jpeg_stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegStream_t *</td>
<td>Input</td>
<td>Host</td>
<td>Bitstream handle</td>
</tr>
</tbody>
</table>

**Returns:**
nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.1.19. nvjpegBufferPinnedCreate()

Creates a pinned buffer handle.

**Signature:**

```c
nvjpegStatus_t nvjpegBufferPinnedCreate(
    nvjpegHandle_t handle,
    nvjpegPinnedAllocator_t* pinned_allocator,
    nvjpegBufferPinned_t* buffer);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>nvjpegPinnedAllocator_t* pinned_allocator</td>
<td>Input</td>
<td>Host</td>
<td>Pinned host memory allocator. See <a href="#">nvjpegPinnedAllocator_t</a> structure description.</td>
</tr>
<tr>
<td>nvjpegBufferPinned_t* buffer</td>
<td>Input/Output</td>
<td>Host</td>
<td>nvJPEG pinned buffer object.</td>
</tr>
</tbody>
</table>

**Returns:**
nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.1.20. nvjpegBufferPinnedDestroy()

Destroys a pinned buffer handle.

**Signature:**

```c
nvjpegStatus_t nvjpegBufferPinnedDestroy(
```
Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegBufferPinned_t buffer</td>
<td>Input</td>
<td>Host</td>
<td>nvJPEG pinned buffer object.</td>
</tr>
</tbody>
</table>

Returns:

`nvjpegStatus_t` — An error code as specified in nvJPEG API Return Codes.

### 2.3.1.21. nvjpegStateAttachPinnedBuffer()

Link the nvJPEG pinned buffer handle to `decoder_state`. The `pinned_buffer` is used by the decoder to store the intermediate information that is used across the decoding stages. Pinned buffer can be attached to different decoder states, which helps to switch between implementations without allocating extra memory.

**Signature:**

```c
nvjpegStatus_t nvjpegStateAttachPinnedBuffer(
    nvjpegJpegState_t decoder_state,
    nvjpegBufferPinned_t pinned_buffer);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegState_t decoder_state</td>
<td>Input</td>
<td>Host</td>
<td>nvJPEG decoder state.</td>
</tr>
<tr>
<td>nvjpegBufferPinned_t pinned_buffer</td>
<td>Input</td>
<td>Host</td>
<td>nvJPEG pinned buffer container.</td>
</tr>
</tbody>
</table>

Returns:

`nvjpegStatus_t` — An error code as specified in nvJPEG API Return Codes.

### 2.3.1.22. nvjpegBufferPinnedRetrieve()

Retrieves the pinned memory pointer and size from the nvJPEG pinned buffer handle. Allows the application to re-use the memory once the decode is complete.

**Signature:**

```c
nvjpegStatus_t nvjpegBufferPinnedRetrieve(
    nvjpegBufferPinned_t buffer,
    size_t* size, void** ptr);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegBufferPinned_t buffer</td>
<td>Input</td>
<td>Host</td>
<td>nvJPEG pinned buffer container.</td>
</tr>
<tr>
<td>size_t* size</td>
<td>Input/Output</td>
<td>Host</td>
<td>Size in bytes of the pinned buffer.</td>
</tr>
</tbody>
</table>
Returns:

`nvjpegStatus_t` — An error code as specified in `nvJPEG API Return Codes`.

### 2.3.1.23. `nvjpegBufferDeviceCreate()`

Creates the device buffer handle.

**Signature:**

```c
nvjpegStatus_t nvjpegBufferDeviceCreate(
    nvjpegHandle_t handle,
    nvjpegDevAllocator_t* device_allocator,
    nvjpegBufferDevice_t* buffer);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegHandle_t handle</code></td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td><code>nvjpegDevAllocator_t* device_allocator</code></td>
<td>Input</td>
<td>Host</td>
<td>Device memory allocator. See the <code>nvJPEG Device Memory Allocator Interface</code> structure description.</td>
</tr>
<tr>
<td><code>nvjpegBufferDevice_t* buffer</code></td>
<td>Input/Output</td>
<td>Host</td>
<td><code>nvJPEG</code> device buffer container.</td>
</tr>
</tbody>
</table>

Returns:

`nvjpegStatus_t` — An error code as specified in `nvJPEG API Return Codes`.

### 2.3.1.24. `nvjpegBufferDeviceDestroy()`

Destroys the device buffer handle.

**Signature:**

```c
nvjpegStatus_t nvjpegBufferDeviceDestroy(
    nvjpegBufferDevice_t buffer);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegBufferDevice_t buffer</code></td>
<td>Input</td>
<td>Host/Device</td>
<td><code>nvJPEG</code> device buffer container. Device pointers are stored within the host structures.</td>
</tr>
</tbody>
</table>

Returns:

`nvjpegStatus_t` — An error code as specified in `nvJPEG API Return Codes`. 

---

`void** ptr` | Input/Output | Host | Pointer to the pinned buffer.
2.3.1.25. `nvjpegStateAttachDeviceBuffer()`

Link the nvJPEG device buffer handle to the `decoder_state`. The `device_buffer` is used by the decoder to store the intermediate information that is used across the decoding stages. Device buffer can be attached to different decoder states, which helps to switch between implementations without allocating extra memory.

**Signature:**

```c
nvjpegStatus_t nvjpegStateAttachDeviceBuffer(
    nvjpegJpegState_t decoder_state,
    nvjpegBufferDevice_t device_buffer);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegState_t decoder_state</td>
<td>Input</td>
<td>Host</td>
<td>nvJPEG decoder state.</td>
</tr>
<tr>
<td>nvjpegBufferDevice_t device_buffer</td>
<td>Input</td>
<td>Host/Device</td>
<td>nvJPEG device buffer container. Device pointers are stored within the host structures.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

2.3.1.26. `nvjpegBufferDeviceRetrieve()`

Retrieve the device memory pointer and size from the nvJPEG device buffer handle. Allows the application to re-use the memory after the decode is complete.

**Signature:**

```c
nvjpegStatus_t nvjpegBufferDeviceRetrieve(
    nvjpegBufferDevice_t buffer,
    size_t* size,
    void** ptr);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegBufferDevice_t buffer</td>
<td>Input</td>
<td>Host</td>
<td>nvJPEG device buffer container.</td>
</tr>
<tr>
<td>size_t* size</td>
<td>Input/Output</td>
<td>Host</td>
<td>Device buffer size in bytes.</td>
</tr>
<tr>
<td>void** ptr</td>
<td>Input/Output</td>
<td>Host</td>
<td>Pointer to the device buffer.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).
2.3.1.27. nvjpegDecodeParamsCreate()

Creates a handle for the parameters. The parameters that can be programmed include: output format, ROI decode, CMYK to RGB conversion.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeParamsCreate(
    nvjpegHandle_t handle,
    nvjpegDecodeParams_t *decode_params);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>nvjpegDecodeParams_t *decode_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Decode output parameters.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

2.3.1.28. nvjpegDecodeParamsDestroy()

Destroys the decode_params handle.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeParamsDestroy(
    nvjpegDecodeParams_t *decode_params);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegDecodeParams_t *decode_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Decode output parameters.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

2.3.2. Retrieve Encoded Image Information API

The helper functions for retrieving the encoded image information.

2.3.2.1. nvjpegGetImageInfo()

Decodes the JPEG header and retrieves the basic information about the image.

**Signature:**

```c
nvjpegStatus_t nvjpegGetImageInfo(
    nvjpegHandle_t handle,
    const unsigned char *data,
```
Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>const unsigned char *data</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the encoded data.</td>
</tr>
<tr>
<td>size_t length</td>
<td>Input</td>
<td>Host</td>
<td>Size of the encoded data in bytes.</td>
</tr>
<tr>
<td>int *nComponents</td>
<td>Output</td>
<td>Host</td>
<td>Pointer to the first element of array of size NVJPEG_MAX_COMPONENT, where the width of each channel (up to NVJPEG_MAX_COMPONENT) will be saved. If the channel is not encoded, then the corresponding value would be zero.</td>
</tr>
<tr>
<td>int *widths</td>
<td>Output</td>
<td>Host</td>
<td>Pointer to the first element of array of size NVJPEG_MAX_COMPONENT, where the height of each channel (up to NVJPEG_MAX_COMPONENT) will be saved. If the channel is not encoded, then the corresponding value would be zero.</td>
</tr>
<tr>
<td>int *heights</td>
<td>Output</td>
<td>Host</td>
<td>Pointer to the first element of array of size NVJPEG_MAX_COMPONENT, where the height of each channel (up to NVJPEG_MAX_COMPONENT) will be saved. If the channel is not encoded, then the corresponding value would be zero.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.2.2. nvJPEG Stream API

These functions store the parsed bit-stream data on the host.

2.3.2.2.1. nvjpegJpegStreamParse()

 Parses the bitstream and stores the metadata in the jpeg_stream struct.

Signature:

nvjpegStatus_t nvjpegJpegStreamParse(
    const unsigned char *data,
    size_t length,
    int save_metadata,
    int save_stream,
    nvjpegJpegStream_t jpeg_stream);
Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>const unsigned char *data</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the bit-stream.</td>
</tr>
<tr>
<td>size_t length</td>
<td>Input</td>
<td>Host</td>
<td>Bit-stream size.</td>
</tr>
<tr>
<td>int save_metadata</td>
<td>Input</td>
<td>Host</td>
<td>[Not enabled. Marked for future use]. If not 0, then the JPEG stream metadata (headers, app markers, etc.) will be saved in the internal JpegStream structure for future usage. If 0, then the meta data (headers, app markers etc.) will be discarded.</td>
</tr>
<tr>
<td>int save_stream</td>
<td>Input</td>
<td>Host</td>
<td>If not 0, then the whole jpeg stream will be copied to the internal JpegStream structure, and the pointer to the JPEG file data will not be needed after this call. If 0, then JpegStream will just save the pointers to JPEG file data, and these pointers will be used later during the image decoding.</td>
</tr>
<tr>
<td>nvjpegJpegStream_t jpeg_stream</td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>The nvJPEG bitstream handle that stores the parsed bitstream information.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.2.2.2. nvjpegJpegStreamParseHeader()

Parses only the header of the bit-stream and stores the header information in the jpeg_stream struct.

Signature:

```c
nvjpegStatus_t nvjpegJpegStreamParseHeader(
    nvjpegHandle_t handle,
    const unsigned char *data,
    size_t length,
    nvjpegJpegStream_t jpeg_stream);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
</tbody>
</table>
2.3.2.2.3. `nvjpegJpegStreamParseTables()`

To be used when decoding TIFF files with JPEG compression. Parses the JPEG tables bitstream and stores the jpeg tables in `jpeg_stream`.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStreamParseTables(
    nvjpegHandle_t handle,
    const unsigned char *data,
    size_t length,
    nvjpegJpegStream_t jpeg_stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>const unsigned char *data</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the JPEG tables bitstream. Can be set to NULL to reset the JPEG tables.</td>
</tr>
<tr>
<td>size_t length</td>
<td>Input</td>
<td>Host</td>
<td>JPEG tables bitstream size.</td>
</tr>
<tr>
<td>nvjpegJpegStream_t jpeg_stream</td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>The nvJPEG bitstream handle that stores the parsed bitstream information.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

2.3.2.2.4. `nvjpegJpegStreamGetFrameDimensions()`

Extracts the JPEG frame dimensions from the bitstream.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStreamGetFrameDimensions(
    nvjpegJpegStream_t jpeg_stream,
    unsigned int* width,
    unsigned int* height);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegStream_t jpeg_stream</td>
<td>Input/Output</td>
<td>Host</td>
<td>The nvJPEG bitstream handle that stores the parsed bitstream information.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).
### 2.3.2.2.5. `nvjpegJpegStreamGetComponentsNum()`

Extracts the JPEG frame dimensions from the bitstream.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStreamGetComponentsNum(
    nvjpegJpegStream_t jpeg_stream,
    unsigned int* components_num);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegJpegStream_t</code> jpeg_stream</td>
<td>Input</td>
<td>Host</td>
<td>Bitstream handle.</td>
</tr>
<tr>
<td><code>unsigned int* components_num</code></td>
<td>Output</td>
<td>Host</td>
<td>Number of encoded channels in the input.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](https://docs.nvidia.com/cuda/nvjpeg-api/index.html#nvjpeg-status).

### 2.3.2.2.6. `nvjpegJpegStreamGetComponentDimensions()`

Extracts the component dimensions from the bitstream.

**Signature:**

```c
nvjpegStatus_t nvjpegJpegStreamGetComponentDimensions(
    nvjpegJpegStream_t jpeg_stream,
    unsigned int component,
    unsigned int* width,
    unsigned int* height);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegJpegStream_t</code> jpeg_stream</td>
<td>Input</td>
<td>Host</td>
<td>Bitstream handle.</td>
</tr>
<tr>
<td><code>unsigned int</code> component</td>
<td>Input</td>
<td>Host</td>
<td>Component index.</td>
</tr>
<tr>
<td><code>unsigned int* width</code></td>
<td>Output</td>
<td>Host</td>
<td>Component height.</td>
</tr>
<tr>
<td><code>unsigned int* height</code></td>
<td>Output</td>
<td>Host</td>
<td>Component width.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](https://docs.nvidia.com/cuda/nvjpeg-api/index.html#nvjpeg-status).
nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.2.2.7. nvjpegJpegStreamGetChromaSubsampling()

Gets the chroma subsampling from the jpeg_stream. For grayscale (single channel) images it returns NVJPEG_CSS_GRAY. For 3-channel images it tries to assign one of the known chroma sub-sampling values based on the sampling information present in the bitstream, else it returns NVJPEG_CSS_UNKNOWN. If the number of channels is 2 or 4, then it returns NVJPEG_CSS_UNKNOWN.

Signature:

```c
nvjpegStatus_t nvjpegJpegStreamGetChromaSubsampling(
    nvjpegJpegStream_t jpeg_stream,
    nvjpegChromaSubsampling_t* chroma_subsampling);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegStream_t jpeg_stream</td>
<td>Input</td>
<td>Host</td>
<td>Bitstream handle.</td>
</tr>
<tr>
<td>nvjpegChromaSubsampling_t* chroma_subsampling</td>
<td>Output</td>
<td>Host</td>
<td>Chroma subsampling for the 1- or 3- channel encoding.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.2.2.8. nvjpegJpegStreamGetJpegEncoding()

This function obtains the JPEG encoding type from the jpeg_stream. For baseline images it returns NVJPEG_ENCODING_BASELINE_DCT. For progressive images it returns NVJPEG_ENCODING_PROGRESSIVE_DCT_HUFFMAN.

Signature:

```c
nvjpegStatus_t nvjpegJpegStreamGetJpegEncoding(
    nvjpegJpegStream_t jpeg_stream,
    nvjpegJpegEncoding_t* jpeg_encoding);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jpeg_stream</td>
<td>In</td>
<td>Host</td>
<td>Input bitstream handle.</td>
</tr>
<tr>
<td>jpeg_encoding</td>
<td>Out</td>
<td>Host</td>
<td>Encoding type obtained—baseline or progressive.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.
2.3.2.2.9. nvjpegJpegStreamGetExifOrientation()

Extracts the exif orientation from the bitstream. Returns NVJPEG_ORIENTATION_UNKNOWN if the exif marker/orientation information is not present.

**Signature:**

```
nvjpegStatus_t NVJPEGAPI nvjpegJpegStreamGetExifOrientation(
    nvjpegJpegStream_t jpeg_stream,
    nvjpegExifOrientation_t *orientation_flag);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegJpegStream_t jpeg_stream</td>
<td>Input</td>
<td>Host</td>
<td>Bitstream handle.</td>
</tr>
<tr>
<td>nvjpegExifOrientation_t *orientation_flag</td>
<td>Output</td>
<td>Host</td>
<td>Exif orientation in JPEG stream.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

2.3.3. Decode API—Single Phase

Functions for decoding single image or batched images in a single phase.

2.3.3.1. nvjpegDecode()

Decodes a single image, and writes the decoded image in the desired format to the output buffers. This function is asynchronous with respect to the host. All GPU tasks for this function will be submitted to the provided stream.

From CUDA 11 onwards, `nvjpegDecode()` picks the best available back-end for a given image, user no longer has control on this. If there is a need to select the back-end, then consider using `nvjpegDecodeJpeg`. This is a new API added in CUDA 11 which allows user to control the back-end.

**Signature:**

```
nvjpegStatus_t nvjpegDecode(
    nvjpegHandle_t          handle,
    nvjpegJpegState_t       jpeg_handle,
    const unsigned char     *data,
    size_t                  length,
    nvjpegOutputFormat_t    output_format,
    nvjpegImage_t           *destination,
    cudaStream_t            stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t jpeg_handle</td>
<td>Input</td>
<td>Host</td>
<td>The image state handle.</td>
</tr>
</tbody>
</table>
const unsigned char *data | Input | Host | Pointer to the encoded data.
size_t length | Input | Host | Size of the encoded data in bytes.
nvjpegOutputFormat_t output_format | Input | Host | Format in which the decoded output will be saved.
nvjpegImage_t *destination | Input/Output | Host/Device | Pointer to the structure that describes the output destination. This structure should be on the host (CPU), but the pointers in this structure should be pointing to the device (i.e., GPU) memory. See nvjpegImage_t.
cudaStream_t stream | Input | Host | The CUDA stream where all of the GPU work will be submitted.

Returns:
nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

### 2.3.3.2. nvjpegDecodeBatchedInitialize()

This function initializes the batched decoder state. The initialization parameters include the batch size, the maximum number of CPU threads, and the specific output format in which the decoded image will be saved. This function should be called once, prior to decoding the batches of images. Any currently running batched decoding should be finished before calling this function.

**Signature:**

```
nvjpegStatus_t nvjpegDecodeBatchedInitialize(
    nvjpegHandle_t         handle,
    nvjpegJpegState_t       jpeg_handle,
    int                     batch_size,
    int                     max_cpu_threads,
    nvjpegOutputFormat_t    output_format);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t jpeg_handle</td>
<td>Input</td>
<td>Host</td>
<td>The image state handle.</td>
</tr>
<tr>
<td>int batch_size</td>
<td>Input</td>
<td>Host</td>
<td>Batch size.</td>
</tr>
<tr>
<td>int max_cpu_threads</td>
<td>Input</td>
<td>Host</td>
<td>This parameter is no longer used by the library.</td>
</tr>
<tr>
<td>nvjpegOutputFormat_t output_format</td>
<td>Input</td>
<td>Host</td>
<td>Format in which the decoded output will be saved.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.
### 2.3.3.3. `nvjpegDecodeBatched()`

Decodes the batch of images, and writes them to the buffers described in the `destination` parameter in a format provided to `nvjpegDecodeBatchedInitialize()` function. This function is asynchronous with respect to the host. All GPU tasks for this function will be submitted to the provided stream.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeBatched(
    nvjpegHandle_t       handle,  
    nvjpegJpegState_t    jpeg_handle,  
    const unsigned char *const *data,  
    const size_t         *lengths,  
    nvjpegImage_t        *destinations,  
    cudaStream_t         stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegHandle_t handle</code></td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td><code>nvjpegJpegState_t jpeg_handle</code></td>
<td>Input</td>
<td>Host</td>
<td>The image state handle.</td>
</tr>
<tr>
<td><code>const unsigned char *const *data</code></td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the first element of array of the input data. The size of the array is assumed to be batch_size provided to <code>nvjpegDecodeBatchedInitialize()</code> batch initialization function.</td>
</tr>
<tr>
<td><code>const size_t *lengths</code></td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the first element of array of input sizes. Size of array is assumed to be batch_size provided to <code>nvjpegDecodeBatchedInitialize()</code>, the batch initialization function.</td>
</tr>
<tr>
<td><code>nvjpegImage_t *destinations</code></td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>Pointer to the first element of array of output descriptors. The size of array is assumed to be batch_size provided to <code>nvjpegDecodeBatchedInitialize()</code>, the batch initialization function. See also <code>nvjpegImage_t</code>.</td>
</tr>
<tr>
<td><code>cudaStream_t stream</code></td>
<td>Input</td>
<td>Host</td>
<td>The CUDA stream where all the GPU work will be submitted.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.3.4. `nvjpegDecodeBatchedEx()`

This API helps to Decodes the batch of images with ROI, and writes them to the buffers described in the `destination` parameter in a format provided to
nvjpegDecodeBatchedInitialize() function. This function is asynchronous with respect to the host. All GPU tasks for this function will be submitted to the provided stream.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeBatchedEx(
    nvjpegHandle_t handle,
    nvjpegJpegState_t jpeg_handle,
    const unsigned char *const *data,
    const size_t *lengths,
    nvjpegImage_t *destinations,
    nvjpegDecodeParams_t *decode_params,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>nvjpeg library handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t jpeg_handle</td>
<td>Input</td>
<td>Host</td>
<td>The image state handle.</td>
</tr>
<tr>
<td>const unsigned char *const *data</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the first element of array of the input data. The size of the array is assumed to be batch_size provided to nvjpegDecodeBatchedInitialize() batch initialization function.</td>
</tr>
<tr>
<td>const size_t *lengths</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the first element of array of input sizes.</td>
</tr>
<tr>
<td>nvjpegImage_t *destinations</td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>Pointer to the first element of array of output descriptors. The size of array is assumed to be batch_size provided to nvjpegDecodeBatchedInitialize(), the batch initialization function. See also nvjpegImage_t.</td>
</tr>
<tr>
<td>nvjpegDecodeParams_t *decode_params</td>
<td>Input</td>
<td>Host</td>
<td>Setting ROI Decode parameters</td>
</tr>
<tr>
<td>cudaStream_t stream</td>
<td>Input</td>
<td>Host</td>
<td>The CUDA stream where all the GPU work will be submitted.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.3.5. nvjpegDecodeBatchSupported()

This API helps determine whether an image can be decoded by `nvjpegDecodeBatched`. User can parse the bitstream header using `nvjpegJpegStreamParseHeader` and then call this API to determine whether the image can be decoded.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeBatchSupported(
```

nvJPEG
nvjpegHandle_t handle,
nvjpegJpegStream_t jpeg_stream,
int* is_supported);

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.3.6. nvjpegDecodeBatchedSupportedEx()

This API helps determine whether an image can be decoded by nvjpegDecodeBatchedEx. User can parse the bitstream header using nvjpegJpegStreamParseHeader and set the ROI in the decode params then call this API to determine whether the image can be decoded.

Signature:

nvjpegStatus_t nvjpegDecodeBatchedSupportedEx(
    nvjpegHandle_t handle,
    nvjpegJpegStream_t jpeg_stream,
    nvjpegDecodeParams_t decode_params,
    int* is_supported);

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>

<tr>
<td>int* is_supported</td>
<td>Output</td>
<td>Host</td>
<td>Return value of 0 indicates bitstream can be decoded by the decoder_handle, non zero value indicates that the bitstream is not supported.</td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.
2.3.3.7. **nvjpegDecodeBatchedPreAllocate()**

This is an experimental API that can be used with `nvjpegDecodeBatched`. When decoding images with varying sizes and chroma subsampling, performance is limited by the repeated cuda calls made by the library to free/allocate device memory. This API attempts to avoid this problem by allocating device memory prior to the actual decoding. Users have the option to call this API with values that are unlikely to be exceeded when `nvjpegDecodeBatched` is called.

**Note:**

This functionality is available only when the `nvjpegHandle_t` is instantiated using `NVJPEG_BACKEND_HARDWARE`. It is currently a No Op for other backends.

This API only provides a hint for initial allocation. If the image dimensions at the time of decode exceed what was provided, then the library will resize the device buffers.

If the images being decoded have different chroma subsamplings, then the `chroma_subsampling` field should be set to `NVJPEG_CSS_444` to ensure that the device memory can be reused.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeBatchedPreAllocate(
    nvjpegHandle_t          handle,
    nvjpegJpegState_t       jpeg_handle,
    int                     batch_size,
    int                     width,
    int                     height,
    nvjpegChromaSubsampling_t chroma_subsampling,
    nvjpegOutputFormat_t    output_format);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegHandle_t</code> handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td><code>nvjpegJpegState_t</code> jpeg_handle</td>
<td>Input</td>

</tr>
<tr>
<td><code>int</code> batch_size</td>
<td>Input</td>
<td>Host</td>
<td>Batch size.</td>
</tr>
<tr>
<td><code>int</code> width</td>
<td>Input</td>
<td>Host</td>
<td>Maximum width of image that will be decoded.</td>
</tr>
<tr>
<td><code>int</code> height</td>
<td>Input</td>
<td>Host</td>
<td>Maximum height of image that will be decoded.</td>
</tr>
<tr>
<td><code>nvjpegChromaSubsampling_t</code> chroma_subsampling</td>
<td>Input</td>
<td>Host</td>
<td>Chroma-subsampling of the images.</td>
</tr>
<tr>
<td><code>nvjpegOutputFormat_t</code> output_format</td>
<td>Input</td>
<td>Host</td>
<td>Format in which the decoded output will be saved.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).
2.3.3.8. nvjpegDecodeBatchedParseJpegTables()

To be used along with batched decode APIs when decoding JPEG bitstreams from a TIFF file. This function parses the JPEG tables bitstream to extract the JPEG tables. The external Huffman and quantization tables will be applied to all the JPEG bitstreams in the batch.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeBatchedParseJpegTables(
    nvjpegHandle_t handle,
    nvjpegJpegState_t jpeg_handle,
    const unsigned char *data,
    const size_t length);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t jpeg_handle</td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>The image state handle.</td>
</tr>
<tr>
<td>const unsigned char *data</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the JPEG tables bitstream. Can be set to NULL to reset the jpeg tables.</td>
</tr>
<tr>
<td>size_t length</td>
<td>Input</td>
<td>Host</td>
<td>JPEG tables bitstream size.</td>
</tr>
</tbody>
</table>

**Returns:**

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

2.3.4. Decode API—Decoupled Decoding

This set of decoding API works with the bitstream handles, decode parameter handles, pinned and device buffers handles as input, thus decoupling JPEG bitstream parse, buffer management and setting up decoder parameters from the decode process itself.

Currently only multiphase decoding is available. Multiphase decoupled single image decoding consists of three phases:

- Host
- Mixed
- Device

Each of the above decodings is carried on according to its individual semantics. Phases on different images can be carried out with different decoding state handles simultaneously, while sharing of some helper objects is possible. See the details of semantics in the individual phases descriptions.

Below are a couple of examples of using decoupled API.
The following snippet explains how to use the API to prefetch the host stage of the processing: first do all of the host work on the host, and then submit the rest of decoding work to the device.

```c
#define BATCH_SIZE 2
nvjpegHandle_t nvjpeg_handle;
nvjpegState_t nvjpeg_decoder_state[BATCH_SIZE];
nvjpegPinned_t nvjpeg_pinned_buffer[BATCH_SIZE];
nvjpegDevice_t nvjpeg_device_buffer;
nvjpegStream_t nvjpeg_jpeg_stream[BATCH_SIZE];
nvjpegDecodeParams_t nvjpeg_decode_params;
nvjpegDecoder_t nvjpeg_decoder;
nvjpegBackend_t impl = NVJPEG_BACKEND_DEFAULT;

unsigned char* bitstream[BATCH_SIZE] // pointers jpeg bitstreams
size_t length[BATCH_SIZE]; // bitstream sizes

nvjpegImage_t output_images[BATCH_SIZE];

// all the images in the batch will be decoded as RGBI
nvjpegDecodeParamsSetOutputFormat(nvjpeg_decode_params, NVJPEG_OUTPUT_RGBI);

// call host phase for two bitstreams
for (int i = 0; i < BATCH_SIZE; i++)
{
    nvjpegStreamParse(nvjpeg_handle, bitstream[i], length[i], 0, 0,
    nvjpeg_jpeg_stream[i]);
    nvjpegStateAttachPinnedBuffer(nvjpeg_decoder_state[i], nvjpeg_pinned_buffer[i]);
    nvjpegDecodeJpegHost(nvjpeg_handle, nvjpeg_decoder, nvjpeg_decoder_state[i],
    nvjpeg_decode_params, nvjpeg_jpeg_stream[i])
}

for (int i = 0; i < BATCH_SIZE; i++)
{
    // same device buffer being used for decoding bitstreams
    nvjpegStateAttachDeviceBuffer(nvjpeg_decoder_state[i], nvjpeg_device_buffer);

    // cuda stream set to NULL
    nvjpegDecodeJpegToDevice(nvjpeg_handle, nvjpeg_decoder, nvjpeg_jpeg_stream[i], NULL);
    // cuda stream set to NULL
    nvjpegDecodeJpegDevice(nvjpeg_handle, nvjpeg_decoder, nvjpeg_decoder_state[i],
    &output_images[i], NULL);
    cudaDeviceSynchronize();
}
```

The following snippet explains how pinned and device buffers can be shared across two instances of `nvJPEG Decoder Handle`.

```c
#define BATCH_SIZE 4
nvjpegHandle_t nvjpeg_handle;
nvjpegDecoder_t nvjpeg_decoder_impl1;
nvjpegDecoder_t nvjpeg_decoder_impl2;
nvjpegState_t nvjpeg_decoder_state_impl1;
nvjpegState_t nvjpeg_decoder_state_impl2;
nvjpegPinned_t nvjpeg_pinned_buffer;
nvjpegDevice_t nvjpeg_device_buffer;
nvjpegStream_t nvjpeg_jpeg_stream;
nvjpegDecodeParams_t nvjpeg_decode_params;

unsigned char* bitstream[BATCH_SIZE] // pointers jpeg bitstreams
size_t length[BATCH_SIZE]; // bitstream sizes

// populate bitstream and length correctly for this code to work
nvjpegImage_t output_images[BATCH_SIZE];
```
// allocate device memory for output images, for this snippet to work
nvjpegStateAttachPinnedBuffer(nvjpeg_decoder_state_impl1, nvjpeg_pinned_buffer);
nvjpegStateAttachPinnedBuffer(nvjpeg_decoder_state_impl2, nvjpeg_pinned_buffer);
nvjpegStateAttachDeviceBuffer(nvjpeg_decoder_state_impl1, nvjpeg_device_buffer);
nvjpegStateAttachDeviceBuffer(nvjpeg_decoder_state_impl2, nvjpeg_device_buffer);

// all the images in the batch will be decoded as RGBI
nvjpegDecodeParamsSetOutputFormat(nvjpeg_decode_params, NVJPEG_OUTPUT_RGBI);

for (int i = 0; i < BATCH_SIZE; i++)
{
    nvjpegJpegStreamParse(nvjpeg_handle, bitstream[i], length[i], 0, 0, nvjpeg_jpeg_stream);

    // decide which implementation to use, based on image size
    unsigned int frame_width;
    unsigned int frame_height;
    nvjpegJpegStreamGetFrameDimensions(nvjpeg_jpeg_stream, &frame_width, &frame_height);
    nvjpegJpegDecoder_t& decoder = (frame_height * frame_width > 1024 * 768) ? nvjpeg_decoder_impl2 : nvjpeg_decoder_impl1;
    nvjpegJpegState_t& decoder_state = (frame_height * frame_width > 1024 * 768) ? nvjpeg_decoder_state_impl2 : nvjpeg_decoder_state_impl1;

    nvjpegDecodeJpegHost(nvjpeg_handle, decoder, decoder_state, nvjpeg_decode_params, nvjpeg_jpeg_stream);

    // cuda stream set to NULL
    nvjpegDecodeJpegTransferToDevice(nvjpeg_handle, decoder, decoder_state, nvjpeg_jpeg_stream, NULL);

    // cuda stream set to NULL
    nvjpegDecodeJpegDevice(nvjpeg_handle, nvjpeg_decoder, decoder_state, &output_images, NULL);
    cudaDeviceSynchronize();
}

2.3.4.1. nvjpegDecodeJpegHost()

This is the first stage of the decoupled decoding process. It is done entirely on the host, hence it is synchronous with respect to the host.

If a pinned buffer is attached to the decoder state, then the pinned buffer object will be used to allocate the pinned memory required for the host decoding phase. There wouldn’t be allocation if the pinned buffer object already handles the required amount of pinned memory.

If a pinned buffer object is not attached, then the state will use heap host memory to allocate the memory required for the host processing.

In this phase, device is not participating. Hence the device selection, device initialization, and device memory initialization can be done later in the decoding process.

This function works on a parsed stream. The parsed stream handle that is available after calling the nvjpegJpegStreamParse() function should be provided to this function.

Signature:

```
nvjpegStatus_t nvjpegDecodeJpegHost(
    nvjpegHandle_t handle,
    nvjpegJpegDecoder_t decoder,
    nvjpegJpegState_t decoder_state,
    nvjpegDecodeParams_t decode_params,
    nvjpegJpegStream_t jpeg_stream);
```

Parameters:
Parameter | Input / Output | Memory | Description
--- | --- | --- | ---
nvjpegHandle_t handle | Input | Host | The library handle.
nvjpegJpegDecoder_t decoder | Input | Host | The nvJPEG decoder handle.
nvjpegJpegState_t decoder_state | Input | Host | The nvJPEG decoder state handle.
nvjpegDecodeParams_t decode_params | Input | Host | Handle to decode the output properties.
nvjpegJpegStream_t jpeg_stream | Input | Host | Handle to the parsed bitstream data.

Returns:

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).

### 2.3.4.2. nvjpegDecodeJpegTransferToDevice()

This phase contains both host and device operations. Hence it is a mix of synchronous and asynchronous operations with respect to the host. All the device operations will be submitted to the provided stream.

This phase should be called only after the host phase with the same decoder handle, decoder state handle and parsed jpeg stream handle. Device should be initialized and device buffer should be attached to decoder_state handle using `nvjpegStateAttachDeviceBuffer()` prior to calling this API. This device buffer object will be resized to the required amount of memory if needed. For the host memory buffer, this phase will use whatever was used in the host phase: either the attached pinned buffer or the state’s host memory buffer.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeJpegTransferToDevice(
    nvjpegHandle_t handle,
    nvjpegJpegDecoder_t decoder,
    nvjpegJpegState_t decoder_state,
    nvjpegJpegStream_t jpeg_stream,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
</table>
nvjpegHandle_t handle | Input | Host | The library handle. |
nvjpegJpegDecoder_t decoder | Input | Host | The nvJPEG decoder handle. |
nvjpegJpegState_t decoder_state | Input | Host | The nvJPEG decoder state handle. |
nvjpegJpegStream_t jpeg_stream | Input | Host | Handle to the parsed bitstream data. |

cudaStream_t stream | Input | Host | The CUDA stream to which all the GPU tasks will be submitted. |

Returns:

nvjpegStatus_t — An error code as specified in [nvJPEG API Return Codes](#).
2.3.4.3. nvjpegDecodeJpegDevice()

This phase consists of decode operations that take place mainly on the device (no significant host side computation is done). Hence this phase is asynchronous with respect to the host. This phase should be called after `nvjpegDecodeJpegTransferToDevice()` for a given `decoder_state` handle and `decoder` handle.

In this function call, the host memory buffers are not used, so if the pinned buffer was attached to the state, then it can be reused somewhere else. Note that at this point the Jpeg stream handle is not needed anymore, since parts that are needed for device decoding will be copied to the device memory in the previous phase.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeJpegDevice(
    nvjpegHandle_t handle,
    nvjpegJpegDecoder_t decoder,
    nvjpegJpegState_t decoder_state,
    nvjpegImage_t *destination,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegHandle_t handle</td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td>nvjpegJpegDecoder_t decoder</td>
<td>Input</td>
<td>Host</td>
<td>The nvJPEG decoder handle.</td>
</tr>
<tr>
<td>nvjpegJpegState_t decoder_state</td>
<td>Input</td>
<td>Host</td>
<td>The nvJPEG decoder state handle.</td>
</tr>
<tr>
<td>nvjpegImage_t *destination</td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>Pointer to a structure that describes the output destination. This structure should be on host, but the pointers in this structure should be pointing to the device memory. See <code>nvJPEG Image</code> for details.</td>
</tr>
<tr>
<td>cudaStream_t stream</td>
<td>Input</td>
<td>Host</td>
<td>The CUDA stream to which all the GPU tasks will be submitted.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in `nvJPEG API Return Codes`.

2.3.4.4. nvjpegDecodeJpeg()

This is a single phase API with the flexibility to select nvJPEG back-end when creating an `nvjpegJpegDecoder_t` object. The user has the option to call this API instead of making three separate calls to `nvjpegDecodeJpegHost()`, `nvjpegDecodeJpegTransferToDevice()`, and `nvjpegDecodeJpegDevice()`.

It is required to attach the device buffer to the decoder state before calling this API. The pinned buffer is optional. If the pinned buffer is not attached, then heap memory will be used for host processing.
This function works on a parsed stream. The parsed stream handle that is available after calling the `nvJPEGJpegStreamParse()` function should be provided to this function.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeJpeg(
    nvjpegHandle_t handle,
    nvjpegJpegDecoder_t decoder,
    nvjpegJpegState_t decoder_state,
    nvjpegJpegStream_t jpeg_bitstream,
    nvjpegImage_t *destination,
    nvjpegDecodeParams_t decode_params,
    cudaStream_t stream);
```

### Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>nvjpegHandle_t handle</code></td>
<td>Input</td>
<td>Host</td>
<td>The library handle.</td>
</tr>
<tr>
<td><code>nvjpegJpegDecoder_t decoder</code></td>
<td>Input</td>
<td>Host</td>
<td>The nvJPEG decoder handle.</td>
</tr>
<tr>
<td><code>nvjpegJpegState_t decoder_state</code></td>
<td>Input</td>
<td>Host</td>
<td>The nvJPEG decoder state handle.</td>
</tr>
<tr>
<td><code>nvjpegJpegStream_t jpeg_stream</code></td>
<td>Input</td>
<td>Host</td>
<td>Handle to the parsed bitstream data.</td>
</tr>
<tr>
<td><code>nvjpegImage_t *destination</code></td>
<td>Input/Output</td>
<td>Host/Device</td>
<td>Pointer to a structure that describes the output destination. This structure should be on the host, but the pointers in this structure should be pointing to the device memory. See nvJPEG Image for details.</td>
</tr>
<tr>
<td><code>nvjpegDecodeParams_t decode_params</code></td>
<td>Input</td>
<td>Host</td>
<td>The handle which stores the decode output properties.</td>
</tr>
<tr>
<td><code>cudaStream_t stream</code></td>
<td>Input</td>
<td>Host</td>
<td>The CUDA stream to which all the GPU tasks will be submitted.</td>
</tr>
</tbody>
</table>

### Returns:

- `nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

#### 2.3.5. nvJPEG Decode Parameters

This category of APIs is used to set the decoding parameters. These APIs should be used with the decode APIs defined in [Decode API—Decoupled Decoding](#).

##### 2.3.5.1. nvjpegDecodeParamsSetOutputFormat()

This function is used to set the decode output format. See `nvjpegOutputFormat_t` described in step 6 of [Single Image Decoding](#). The output parameter of `nvjpegOutputFormat_t` defaults to `NVJPEG_OUTPUT_UNCHANGED` if not set using this API.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeParamsSetOutputFormat(
```
nvjpegDecodeParams_t decode_params,
nvjpegOutputFormat_t output_format);

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegDecodeParams_t</td>
<td>Input</td>
<td>Host</td>
<td>Decode output parameter handle.</td>
</tr>
<tr>
<td>decode_params</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>nvjpegOutputFormat_t</td>
<td>Input</td>
<td>Host</td>
<td>See step 6 of Single Image Decoding.</td>
</tr>
<tr>
<td>output_format</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns:

nvjpegStatus_t — An error code as specified in nvJPEG API Return Codes.

2.3.5.2. nvjpegDecodeParamsSetROI()

This function enables the region of interest-only (ROI-only) decode. To disable the ROI-only, i.e., to decode the whole image, set:

- offset_x = 0,
- offset_y = 0,
- roi_width = -1, and
- roi_height = -1.

**Note:** ROI decode is disabled by default. It is not supported when the nvJPEG decoder handle is created using NVJPEG_BACKEND_HARDWARE.

The ROI window cannot go out of image bounds. That is:

- offset_x cannot be lower than zero, or
- offset_x + roi_width cannot be larger than the JPEG image width.

If the output format is NVJPEG_OUTPUT_YUV or NVJPEG_OUTPUT_UNCHANGED, then the offset_x and offset_y values have to be multiples of the maximum subsampling factor, as defined in the JPEG standard.

Signature:

```
nvjpegStatus_t nvjpegDecodeParamsSetROI(
    nvjpegDecodeParams_t decode_params,
    int offset_x,
    int offset_y,
    int roi_width,
    int roi_height);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegDecodeParams_t</td>
<td>Input</td>
<td>Host</td>
<td>The decode output parameter handle.</td>
</tr>
<tr>
<td>decode_params</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
2.3.5.3. `nvjpegDecodeParamsSetAllowCMYK()`

If enabled, the nvJPEG library assumes that the JPEG with 4 encoded color components is in CMYK colorspace, and enables the conversion to RGB/YUV colorspace. The CMYK-to-RGB conversion is disabled by default. The conversion is based on the subtractive scheme—this behavior matches OpenCV’s handling of 4-component JPEGs.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeParamsSetAllowCMYK(
    nvjpegDecodeParams_t decode_params,
    int allow_cmyk);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>decode_params</code></td>
<td>Input</td>
<td>Host</td>
<td>Decode output parameter handle.</td>
</tr>
<tr>
<td><code>allow_cmyk</code></td>
<td>Input</td>
<td>Host</td>
<td>Enable CMYK to RGB conversion.</td>
</tr>
</tbody>
</table>

**Returns:**

`nvjpegStatus_t` — An error code as specified in `nvJPEG API Return Codes`.

2.3.5.4. `nvjpegDecodeParamsSetScaleFactor()`

Allows the user to scale decode output.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeParamsSetScaleFactor(
    nvjpegDecodeParams_t decode_params,
    nvjpegScaleFactor_t scale_factor);
```

**Parameters:**

**Note:** This feature is currently supported only when nvJPEG decoder handle is created using `NVJPEG_BACKEND_HARDWARE`. 
The scale factor is set to NVJPEG_SCALE_NONE by default. The supported values are listed here.

When setting a scale factor value, the recommended allocation of the destination parameters is as follows:

- Use `nvjpegGetImageInfo()` or `nvjpegJpegStreamGetFrameDimensions()` to extract the dimensions of each channel.
- Let `height[NVJPEG_MAX_COMPONENT]` and `width[NVJPEG_MAX_COMPONENT]` be 2 arrays which store the height and width. The index to these arrays correspond to the channel id.
- For a channel `c`, the scaled dimensions are calculated as follows:
  - `scaled_height[c] = (height[c] + rounding_factor - 1)/rounding_factor`
  - `scaled_width[c] = (width[c] + rounding_factor - 1)/rounding_factor`
  - `when scale_factor = NVJPEG_SCALE_NONE, rounding_factor = 1`
  - `when scale_factor = NVJPEG_SCALE_1_BY_2, rounding_factor = 2`
  - `when scale_factor = NVJPEG_SCALE_1_BY_4, rounding_factor = 4`
  - `when scale_factor = NVJPEG_SCALE_1_BY_8, rounding_factor = 8`

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nvjpegDecodeParams_t</td>
<td>Input</td>
<td>Host</td>
<td>Decode output parameter handle.</td>
</tr>
<tr>
<td>nvjpegScaleFactor_t</td>
<td>Input</td>
<td>Host</td>
<td>Set the scaling factor for the decode output.</td>
</tr>
</tbody>
</table>

For the `output_format`:

| NVJPEG_OUTPUT_YUV             | `destination.pitch[0]` should be at least: `width[0]` | `destination.channel[0]` should be at least of size: `destination.pitch[0]*height[0]` |
| NVJPEG_OUTPUT_YUVA            | `destination.pitch[c]` should be at least:            | `destination.channel[c]` should be at least of size:                                             |
| NVJPEG_OUTPUT_RGB and         | `width[c]` for `c = 0, 1, 2`                          | `destination.pitch[c]*height[c]` for `c = 0, 1, 2`                                               |
| NVJPEG_OUTPUT_BGR             | `width[0]` for `c = 0, 1, 2`                          | `destination.pitch[0]*height[0]` for `c = 0, 1, 2`                                               |
| NVJPEG_OUTPUT_RGBI and        | `width[0]*3`                                          | `destination.pitch[0]*height[0]`                                                                  |
| NVJPEG_OUTPUT_BGRI            | `width[c]` for `c = [0, nComponents - 1]`              | `destination.pitch[c]*height[c]` for `c = [0, nComponents - 1]`                                   |
| NVJPEG_OUTPUT_UNCHANGED       |                                                           |                                                                                                  |

Returns:

`nvjpegStatus_t` — An error code as specified in `nvJPEG API Return Codes`. 
2.3.5.5. `nvjpegDecodeParamsSetExifOrientation()`

This function is used to generate the decoded output based on the exif orientation parameter. When ExifOrientation is enabled, the output buffers should be allocated based on the rotated dimensions. If the orientation is set as `NVJPEG_ORIENTATION_UNKNOWN`, the library will default to `NVJPEG_ORIENTATION_HORIZONTAL`.

**ROI Decode and EXIF rotation**

Exif rotation and ROI Decode can be enabled together. The ROI coordinates should be in the rotated space.

**Signature:**

```c
nvjpegStatus_t nvjpegDecodeParamsSetExifOrientation(
    nvjpegDecodeParams_t decode_params,
    nvjpegExifOrientation_t orientation);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decode_params</td>
<td>Input</td>
<td>Host</td>
<td>Decode output parameter handle.</td>
</tr>
<tr>
<td>orientation</td>
<td>Input</td>
<td>Host</td>
<td>Set the exif orientation for the decode output.</td>
</tr>
</tbody>
</table>

**Returns:**

- `nvjpegStatus_t` — An error code as specified in [nvJPEG API Return Codes](#).

2.3.6. **nvJPEG API Return Codes**

The nvJPEG API adheres to the following return codes and their indicators:

```c
typedef enum {
    NVJPEG_STATUS_SUCCESS = 0,
    NVJPEG_STATUS_NOT_INITIALIZED = 1,
    NVJPEG_STATUS_INVALID_PARAMETER = 2,
    NVJPEG_STATUS_BAD_JPEG = 3,
    NVJPEG_STATUS_JPEG_NOT_SUPPORTED = 4,
    NVJPEG_STATUS_ALLOCATOR_FAILURE = 5,
    NVJPEG_STATUS_EXECUTION_FAILED = 6,
    NVJPEG_STATUS_ARCH_MISMATCH = 7,
    NVJPEG_STATUS_INTERNAL_ERROR = 8,
    NVJPEG_STATUS_IMPLEMENTATION_NOT_SUPPORTED = 9
} nvjpegStatus_t;
```

**Description of the returned error codes:**

<table>
<thead>
<tr>
<th>Returned Error (Returned Code)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_STATUS_SUCCESS (0)</td>
<td>The API call has finished successfully. Note that many of the calls are asynchronous and some of the errors may be seen only after synchronization.</td>
</tr>
</tbody>
</table>
2.3.7. **nvJPEG Chroma Subsampling**

One of the outputs of the `nvjpegGetImageInfo()` API is `nvjpegChromaSubsampling_t`. This parameter is an enum type, and its enumerator list comprises of the chroma subsampling property retrieved from the encoded JPEG image. The `nvjpegGetImageInfo()` function currently supports the following chroma subsampling types:

```c
typedef enum {
    NVJPEG_CSS_444,
    NVJPEG_CSS_422,
    NVJPEG_CSS_420,
    NVJPEG_CSS_440,
    NVJPEG_CSS_411,
    NVJPEG_CSS_410,
    NVJPEG_CSS_GRAY,
    NVJPEG_CSS_410V,
    NVJPEG_CSS_UNKNOWN
} nvjpegChromaSubsampling_t;
```

2.3.8. **Reference Documents**

Refer to the JPEG standard: [https://jpeg.org/jpeg/](https://jpeg.org/jpeg/)
2.4. Examples of nvJPEG

nvJPEG Decode sample can be found here: [https://github.com/NVIDIA/CUDALibrarySamples/tree/master/nvJPEG/nvJPEG-Decoder](https://github.com/NVIDIA/CUDALibrarySamples/tree/master/nvJPEG/nvJPEG-Decoder)
Chapter 3. JPEG Encoding

This section describes the encoding functions of the nvJPEG Library.

3.1. Using the Encoder

The user should perform the below prerequisite steps before calling the nvJPEG encoding functions. See also nvJPEG Encoder Helper API Reference.

3.1.1. Encoding the Parameters

The user should create an encoding parameters structure with \texttt{nvjpegEncoderParamsCreate()} function. The function will be initialized with default parameters. User can use an appropriate \texttt{nvjpegEncoderParamsSet*()} function to set a specific parameter.

The quality parameter can be set, using the \texttt{nvjpegEncoderParamsSetQuality()} function, to an integer value between 1 and 100, and this quality parameter will be used as a base for generating the JPEG quantization tables.

The parameters structure should be passed to compression functions.

\textbf{Note:} The encoding parameters structure can be reused to compress multiple images simultaneously, but no changes to the parameters should be made during the ongoing encoding, or the encoding result will be undefined.

3.1.2. Encoding the State

The user should create the encoding state structure using \texttt{nvjpegEncoderStateCreate()} function. This function will hold intermediate buffers for the encoding process. This state should be passed to the compression functions.

\textbf{Note:} The encoding state structure can be reused to encode a series of images, but no encoding should be performed on multiple images with the same encoding state at the same time—otherwise the result of the encodings will be undefined.
3.1.3. Encoding the Image

The nvJPEG library provides a few interfaces for compressing the image in different formats and colorspaces. See below.

3.1.3.1. nvjpegEncodeYUV

Input for this function is an image in YUV colorspace. See `nvjpegEncodeYUV()`. The `source` argument should be filled with the corresponding YUV planar data. The `chroma_subsampling` argument should have the chroma subsampling of the input data. If the chroma subsampling in the encoding parameters is the same as input chroma subsampling, then the user’s input data will be directly used in the JPEG compression. Otherwise chroma will be resampled to match the chroma subsampling of the encoding parameters.

Input data should be provided with respect to the subsampling factors. That is, the chrominance image planes should have sizes aligned to the corresponding subsamplings. For example:

- Image dimensions: 123x321
- Input chroma subsampling: NVJPEG_CSS_410
- Chroma subsampling factor for this chroma subsampling: 4x2
- Given the above, the encoder library expects the user to provide:
  - Y plane with size: 123 x 321
  - Cb and Cr plane with size: 31 x 161

3.1.3.2. nvjpegEncodeImage

See `nvjpegEncodeImage()`. Input for this function, i.e., how data should be provided in the `source` argument, is determined by the `input_format` argument. For the interleaved formats (ending with `I`) only the first channel is used. For the non-interleaved formats, all the channels in the input format are used.

For example, if the user has interleaved the RGB image of size $W \times H$, stored continuously, and the pointer to it is `pImage`, then `source` should be:

- `source.channel[0] = pImage`
- `source.pitch[0] = W*3`

When the same image is stored in planar format, with image planes pointers stored continuously in the array `pImage[3]`, then `source` should be:

- `source.channel[0] = pImage[0]`
The pitch values for each channel in the source parameter should be set accordingly to the data layout.

The nvJPEG library will perform the color transformation to the YCbCr, and will compress the result.

### 3.1.4. Retrieving the Compressed Stream

Often it is not feasible to accurately predict the final compressed data size of the final JPEG stream for any input data and parameters. The nvJPEG library, while encoding, will calculate the size of the final stream, allocate temporary buffer in the encoder state and save the compressed data in the encoding state’s buffer. In order to get final compressed JPEG stream, the user should provide the memory buffer large enough to store this compressed data. There are two options for how to do this:

1. Use the upper bound on compressed JPEG stream size for the given parameters and image dimensions:
   
   a). Use the `nvjpegEncodeRetrieveBitstream()` function to retrieve the maximum possible JPEG stream size at any given time.
   
   b). Allocate the memory buffer at any given time.
   
   c). Encode the image using one of the encoding functions.
   
   d). Retrieve the compressed JPEG stream from the encoder state after successful encoding, using the `nvjpegEncodeRetrieveBitstream()` and the allocated buffer.

2. Wait for the encoding to complete, and retrieve the exact size of required buffer, as below:
   
   a). Encode the image using one of the encoding functions.
   
   b). Use the `nvjpegEncodeRetrieveBitstream()` function to retrieve the size in bytes of the compressed JPEG stream.
   
   c). Allocate the memory buffer of at least this size.
   
   d). Use the `nvjpegEncodeRetrieveBitstream()` function to populate your buffer with the compressed JPEG stream.

**Note:** As the same encoding image state can be reused to compress a series of images, the `nvjpegEncodeRetrieveBitstream()` function will return the result for the last compressed image.

### 3.1.5. JPEG Encoding Example

See below the example code, and the block diagram shown in Figure 1, for encoding with nvJPEG Encoder.
nvjpegHandle_t nv_handle;
nvjpegEncoderState_t nv_enc_state;
nvjpegEncoderParams_t nv_enc_params;
cudaStream_t stream;

// initialize nvjpeg structures
nvjpegCreateSimple(&nv_handle);
nvjpegEncoderStateCreate(nv_handle, &nv_enc_state, stream);
nvjpegEncoderParamsCreate(nv_handle, &nv_enc_params, stream);

nvjpegImage_t nv_image;
// Fill nv_image with image data, let's say 640x480 image in RGB format

// Compress image
nvjpegEncodeImage(nv_handle, nv_enc_state, nv_enc_params,
    &nv_image, NVJPEG_INPUT_RGB, 640, 480, stream);

// get compressed stream size
size_t length;
nvjpegEncodeRetrieveBitstream(nv_handle, nv_enc_state, NULL, &length, stream);
// get stream itself
cudaStreamSynchronize(stream);
std::vector<char> jpeg(length);
nvjpegEncodeRetrieveBitstream(nv_handle, nv_enc_state, jpeg.data(), &length, 0);

// write stream to file
cudaStreamSynchronize(stream);
std::ofstream output_file("test.jpg", std::ios::out | std::ios::binary);
output_file.write(jpeg.data(), length);
output_file.close();
3.2. nvJPEG Encoder Type Declarations

This section describes the nvJPEG Encoder Type Declarations.

3.2.1. `nvjpegInputFormat_t`

```c
typedef enum {
    NVJPEG_INPUT_RGB         = 3,
    NVJPEG_INPUT_BGR         = 4,
    NVJPEG_INPUT_RGBI        = 5,
    NVJPEG_INPUT_BGRI        = 6
} nvjpegInputFormat_t;
```

The `nvjpegInputFormat_t` enum is used to select the color model and pixel format of the input image. It is used for conversion to YCbCr during encoding.

<table>
<thead>
<tr>
<th>Member</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVJPEG_INPUT_RGB</td>
<td>Input image is in RGB color model. Pixel format is RGB.</td>
</tr>
<tr>
<td>NVJPEG_INPUT_BGR</td>
<td>Input image is in RGB color model. Pixel format is BGR.</td>
</tr>
<tr>
<td>NVJPEG_INPUT_RGBI</td>
<td>Input image is in RGB color model. Pixel format is interleaved RGB.</td>
</tr>
<tr>
<td>NVJPEG_INPUT_BGRI</td>
<td>Input image is in RGB color model. Pixel format is interleaved BGR.</td>
</tr>
</tbody>
</table>

3.2.2. `nvjpegEncoderState_t`

The `nvjpegEncoderState_t` structure stores intermediate buffers and variables used for compression.

3.2.3. `nvjpegEncoderParams_t`

The `nvjpegEncoderParams_t` structure stores JPEG encode parameters.

3.3. nvJPEG Encoder Helper API

Reference

The nvJPEG Encoder helper functions are used for initializing.

3.3.1. `nvjpegEncoderStateCreate()`

Creates encoder state that stores intermediate buffers used in compression.

**Signature:**

```c
nvjpegStatus_t nvjpegEncoderStateCreate(
    nvjpegHandle_t handle,
    nvjpegEncoderState_t *encoder_state,
    cudaStream_t stream);
```
Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle</td>
</tr>
<tr>
<td>encoder_state</td>
<td>Output</td>
<td>Host</td>
<td>Pointer to the encoder state structure, where the new state will be placed.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

3.3.2. nvjpegEncoderStateDestroy()

Destroys the encoder state.

Signature:

```
nvjpegStatus_t nvjpegEncoderStateDestroy(
    nvjpegEncoderState_t encoder_state);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_state</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder state structure that will be released.</td>
</tr>
</tbody>
</table>

3.3.3. nvjpegEncoderParamsCreate()

Creates the structure that holds the compression parameters.

Signature:

```
nvjpegStatus_t nvjpegEncoderParamsCreate(
    nvjpegHandle_t handle,
    nvjpegEncoderParams_t *encoder_params,
    cudaStream_t stream);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>encoder_params</td>
<td>Output</td>
<td>Host</td>
<td>Pointer to the location where the new parameters structure will be placed.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>
3.3.4. **nvjpegEncoderParams_Destroy()**

Destroys the encoder parameters structure.

**Signature:**

```c
nvjpegEncoderParams_Destroy(
    nvjpegEncoderParams_t encoder_params);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder params structure that will be released.</td>
</tr>
</tbody>
</table>

3.3.5. **nvjpegEncoderParamsSetEncoding()**

Sets the parameter quality in the encoder parameters structure.

**Signature:**

```c
nvjpegStatus_t nvjpegEncoderParamsSetEncoding(
    nvjpegEncoderParams_t encoder_params,
    nvjpegJpegEncoding_t etype,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
<tr>
<td>etype</td>
<td>Input</td>
<td>Host</td>
<td>Encoding type selection [Baseline/Progressive]. Default is Baseline.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

3.3.6. **nvjpegEncoderParamsSetQuality()**

Sets the parameter quality in the encoder parameters structure.

**Signature:**

```c
nvjpegStatus_t nvjpegEncoderParamsSetQuality(
    nvjpegEncoderParams_t encoder_params,
    const int quality,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
<tr>
<td>quality</td>
<td>Input</td>
<td></td>
<td></td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>
3.3.7. **nvjpegEncoderParamsSetOptimizedHuffman()**

Sets whether or not to use optimized Huffman. Using optimized Huffman produces smaller JPEG bitstream sizes with the same quality, but with slower performance.

**Signature:**

```c
nvjpegStatus_t nvjpegEncoderParamsSetOptimizedHuffman(
    nvjpegEncoderParams_t encoder_params,
    const int optimized,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
<tr>
<td>optimized</td>
<td>Input</td>
<td>Host</td>
<td>If this value is 0 then non-optimized Huffman will be used. Otherwise optimized version will be used. Default value is 0.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

3.3.8. **nvjpegEncoderParamsSetSamplingFactors()**

Sets which chroma subsampling will be used for JPEG compression.

**Signature:**

```c
nvjpegStatus_t nvjpegEncoderParamsSetSamplingFactors(
    nvjpegEncoderParams_t encoder_params,
    const nvjpegChromaSubsampling_t chroma_subsampling,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
</tbody>
</table>
Chroma subsampling that will be used for JPEG compression. If the input is in YUV color model and chroma_subsampling is different from the subsampling factors of source image, then the NVJPEG library will convert subsampling to the value of chroma_subsampling. Default value is 4:4:4.

| stream | Input | Host | CUDA stream where all the required device operations will be placed. |

3.4. **nvJPEG Encoder API Reference**

This section describes the nvJPEG Encoder API.

3.4.1. **nvjpegEncodeGetBufferSize()**

Returns the maximum possible buffer size that is needed to store the compressed JPEG stream, for the given input parameters.

**Signature:**

```c
nvjpegStatus_t nvjpegEncodeGetBufferSize(
    nvjpegHandle_t handle,
    const nvjpegEncoderParams_t encoder_params,
    int image_width,
    int image_height,
    size_t *max_stream_length);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>encoder_params</td>
<td>Input/Output</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
<tr>
<td>image_width</td>
<td>Input</td>
<td>Host</td>
<td>Input image width.</td>
</tr>
<tr>
<td>image_height</td>
<td>Input</td>
<td>Host</td>
<td>Input image height.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>
3.4.2. nvjpegEncodeYUV()

Compresses the image in YUV colorspace to JPEG stream using the provided parameters, and stores it in the state structure.

**Signature:**

```c
nvjpegStatus_t nvjpegEncodeYUV(
    nvjpegHandle_t handle,
    nvjpegEncoderState_t encoder_state,
    const nvjpegEncoderParams_t encoder_params,
    const nvjpegImage_t *source,
    nvjpegChromaSubsampling_t chroma_subsampling,
    int image_width,
    int image_height,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>encoder_state</td>
<td>Input/Output</td>
<td>Host</td>
<td>Internal structure that holds the temporary buffers required for the compression and also stores the final compressed JPEG stream.</td>
</tr>
<tr>
<td>encoder_params</td>
<td>Input</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
<tr>
<td>source</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the nvjpeg structure that holds the device pointers to the Y, U(Cb) and V(Cr) image planes and the respective strides.</td>
</tr>
<tr>
<td>chroma_subsampling</td>
<td>Input</td>
<td>Host</td>
<td>Chroma subsampling of the input data.</td>
</tr>
<tr>
<td>image_width</td>
<td>Input</td>
<td>Host</td>
<td>Input image width.</td>
</tr>
<tr>
<td>image_height</td>
<td>Input</td>
<td>Host</td>
<td>Input image height.</td>
</tr>
<tr>
<td>stream</td>
<td>Inputt</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

3.4.3. nvjpegEncodeImage()

Compresses the image in the provided format to the JPEG stream using the provided parameters, and stores it in the state structure.

**Signature:**

```c
nvjpegStatus_t nvjpegEncodeImage(
    nvjpegHandle_t handle,
    nvjpegEncoderState_t encoder_state,
    const nvjpegEncoderParams_t encoder_params,
    const nvjpegImage_t *source,
    ...);
```
```c
nvjpegInputFormat_t input_format,
int image_width,
int image_height,
cudaStream_t stream);
```

### Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>encoder_state</td>
<td>Input/Output</td>
<td>Host</td>
<td>Internal structure that holds the temporary buffers required for the compression and also stores the final compressed JPEG stream.</td>
</tr>
<tr>
<td>encoder_params</td>
<td>Input</td>
<td>Host</td>
<td>Encoder parameters structure handle.</td>
</tr>
<tr>
<td>source</td>
<td>Input</td>
<td>Host</td>
<td>Pointer to the <code>nvjpeg</code> structure that holds the device pointers to the Y, U(Cb) and V(Cr) image planes and the respective strides.</td>
</tr>
<tr>
<td>input_format</td>
<td>Input</td>
<td>Host</td>
<td>Value of <code>nvjpegInputFormat_t</code> type that describes the input data.</td>
</tr>
<tr>
<td>image_width</td>
<td>Input</td>
<td>Host</td>
<td>Input image width.</td>
</tr>
<tr>
<td>image_height</td>
<td>Input</td>
<td>Host</td>
<td>Input image height.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

### 3.4.4. `nvjpegEncodeRetrieveBitstream()`

Retrieves the compressed stream from the encoder state that was previously used in one of the encoder functions.

- If `data` parameter is NULL then the encoder will return compressed stream size in the `length` parameter.
- If `data` is not NULL then the provided `length` parameter should contain the `data` buffer size.
- If the provided `length` is less than compressed stream size, then an error will be returned. Otherwise the compressed stream will be stored in the `data` buffer and the actual compressed buffer size will be stored in the `length` parameter.

#### Signature:

```c
nvjpegStatus_t nvjpegEncodeRetrieveBitstream(
    nvjpeHandle_t handle,
    nvjpegEncoderState_t encoder_state,
    unsigned char *data,
    size_t *length,
    cudaStream_t stream);
```
Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>encoder_state</td>
<td>Input/Output</td>
<td>Host</td>
<td>The encoder_state that was previously used in one of the encoder functions.</td>
</tr>
<tr>
<td>data</td>
<td>Input/Output</td>
<td>Host</td>
<td>Pointer to the buffer in the host memory where the compressed stream will be stored. Can be NULL [see description].</td>
</tr>
<tr>
<td>length</td>
<td>Input/Output</td>
<td>Host</td>
<td>Pointer to the input buffer size. On return the NVJPEG library will store the actual compressed stream size in this parameter.</td>
</tr>
<tr>
<td>stream</td>
<td>Input</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

3.4.5. `nvjpegEncodeRetrieveBitstreamDevice()`

Retrieves the compressed stream from the encoder state that was previously used in one of the encoder functions.

- **Data parameter** should be on device memory
- If `data` parameter is NULL then the encoder will return compressed stream size in the `length` parameter.
- If `data` is not NULL then the provided `length` parameter should contain the `data` buffer size.
- If the provided `length` is less than compressed stream size, then an error will be returned. Otherwise the compressed stream will be stored in the `data` buffer and the actual compressed buffer size will be stored in the `length` parameter.

Signature:

```c
nvjpegStatus_t nvjpegEncodeRetrieveBitstreamDevice(
    nvjpegHandle_t handle,
    nvjpegEncoderState_t encoder_state,
    unsigned char *data,
    size_t *length,
    cudaStream_t stream);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>Input</td>
<td>Host</td>
<td>Library handle.</td>
</tr>
<tr>
<td>encoder_state</td>
<td>Input/Output</td>
<td>Host</td>
<td>The encoder_state that was previously used in one of the encoder functions.</td>
</tr>
</tbody>
</table>

nvJPEG
<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Input/Output</td>
<td>Device</td>
</tr>
<tr>
<td>length</td>
<td>Input/Output</td>
<td>Host</td>
</tr>
<tr>
<td>stream</td>

</tr>
</tbody>
</table>
Chapter 4. JPEG Transcoding

This section describes the transcoding functions of the nvJPEG Library.

4.1. nvJPEG Transcoder Helper API Reference

This section describes the nvJPEG Transcoder helper API.

4.1.1. nvjpegEncoderParamsCopyMetadata()

Copies the metadata (JFIF, APP, EXT, and COM markers) from the parsed stream.

Signature:

```c
nvjpegStatus_t nvjpegEncoderParamsCopyMetadata(
    nvjpegEncoderState_t encoder_state,
    nvjpegEncoderParams_t encode_params,
    nvjpegJpegStream_t jpeg_stream,
    cudaStream_t stream);
```

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_state</td>
<td>In/Out</td>
<td>Host</td>
<td>Internal structure that stores the temporary buffers required for the compression.</td>
</tr>
<tr>
<td>encode_params</td>
<td>Out</td>
<td>Host</td>
<td>Encoder parameters that will be used for compression.</td>
</tr>
<tr>
<td>jpeg_stream</td>
<td>In</td>
<td>Host</td>
<td>Input parsed stream.</td>
</tr>
<tr>
<td>stream</td>
<td>In</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

4.1.2. nvjpegEncoderParamsCopyQuantizationTables()

Copies the quantization tables from the parsed stream.
4.1.3. `nvjpegEncoderParamsCopyHuffmanTables()`

Copies the Huffman tables from the parsed stream.

**Signature:**

```c
nvjpegStatus_t nvjpegEncoderParamsCopyHuffmanTables(
    nvjpegEncoderState_t encoder_state,
    nvjpegEncoderParams_t encode_params,
    nvjpegJpegStream_t jpeg_stream,
    cudaStream_t stream);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Input / Output</th>
<th>Memory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoder_state</td>
<td>In/Out</td>
<td>Host</td>
<td>Internal structure that stores the temporary buffers required for the compression.</td>
</tr>
<tr>
<td>encode_params</td>
<td>Out</td>
<td>Host</td>
<td>Encoder parameters that will be used for compression.</td>
</tr>
<tr>
<td>jpeg_stream</td>
<td>In</td>
<td>Host</td>
<td>Input parsed stream.</td>
</tr>
<tr>
<td>stream</td>
<td>In</td>
<td>Host</td>
<td>CUDA stream where all the required device operations will be placed.</td>
</tr>
</tbody>
</table>

4.2. JPEG Transcoding Example

See below the example code.

```c
cudaStream_t stream;
// create Library handle
nvjpegHandle_t handle;
nvjpegCreateSimple(&handle);
```

```c
// nvJPEG decoding
```

```
nvJPEG
```

```
DA-06762-001_v11.7   | 65
```
// create bitstream object
nvjpegJpegStream_t jpeg_stream;
nvjpegJpegStreamCreate(handle, &jpeg_stream);

// parse jpeg stream
nvjpegJpegStreamParse(handle, data_ptr, data_size, 1, 7, 0, jpeg_stream);

// create decoder and decoder state
nvjpegJpegDecoder_t decoder;
nvjpegJpegState_t decoder_state;
nvjpegDecoderCreate(handle, NVJPEG_BACKEND_DEFAULT, &decoder);
nvjpegDecoderStateCreate(handle, decoder, &decoder_state);

// create and set up decoder parameters
nvjpegDecodeParams_t decode_params;
nvjpegDecodeParamsCreate(handle, &decode_params);
nvjpegDecodeParamsSetOutputFormat(decode_params, NVJPEG_OUTPUT_RGBI);

// decode image
nvjpegImage_t output_image;
nvjpegDecodeJpeg(handle, decoder, decode_params, jpeg_stream, decoder_state, &output_image, stream);

// nvJPEG Transcode and encode API
nvjpegEncoderState_t encoder_state;
nvjpegEncoderParams_t encode_params;

// get encoding from the jpeg stream and copy it to the encode parameters
nvjpegJpegStreamGetJpegEncoding(jpeg_stream, &jpeg_encoding);
nvjpegEncoderParamsSetEncoding(encode_params, jpeg_encoding);

// copies according data to the encode parameters
nvjpegEncoderParamsCopyMetadata(encode_params, jpeg_stream, stream);
nvjpegEncoderParamsCopyQuantizationTables(encode_params, jpeg_stream, stream);
nvjpegEncoderParamsCopyHuffmanTables(encode_params, jpeg_stream, stream);

// retrieve frame dimensions
unsigned width, height;
nvjpegJpegStreamGetFrameDimensions(jpeg_stream, &width, &height);

// encode using encode parameters
nvjpegEncodeImage(nvjpeg_handle, encoder_state, encode_params, &output_image, input_format, width, height, stream);

// get compressed stream size
size_t length;
nvjpegEncodeRetrieveBitstream(nvjpeg_handle, encoder_state, NULL, &length, stream);

// get stream itself
cudaStreamSynchronize(stream);
std::vector<char> jpeg(length);
nvjpegEncodeRetrieveBitstream(nvjpeg_handle, encoder_state, jpeg.data(), &length, 0);
Chapter 5. List of Dropped APIs

The following APIs are dropped starting CUDA 11.0

nvjpegStatus_t nvjpegDecodePhaseOne(
    nvjpegHandle_t          handle,
    nvjpegJpegState_t       jpeg_handle,
    const unsigned char     *data,
    size_t                  length,
    nvjpegOutputFormat_t    output_format,
    cudaStream_t            stream);

nvjpegStatus_t nvjpegDecodePhaseTwo(
    nvjpegHandle_t       handle,
    nvjpegJpegState_t    jpeg_handle,
    cudaStream_t         stream);

nvjpegStatus_t nvjpegDecodePhaseThree(
    nvjpegHandle_t       handle,
    nvjpegJpegState_t    jpeg_handle,
    nvjpegImage_t        *destination,
    cudaStream_t         stream);

nvjpegStatus_t nvjpegDecodeBatchedPhaseOne(
    nvjpegHandle_t          handle,
    nvjpegJpegState_t       jpeg_handle,
    const unsigned char     *data,
    size_t                  length,
    int                     image_idx,
    int                     thread_idx,
    cudaStream_t            stream);

nvjpegStatus_t nvjpegDecodeBatchedPhaseTwo(
    nvjpegHandle_t          handle,
    nvjpegJpegState_t       jpeg_handle,
    cudaStream_t            stream);

nvjpegStatus_t nvjpegDecodeBatchedPhaseThree(
    nvjpegHandle_t            handle,
    nvjpegJpegState_t         jpeg_handle,
    nvjpegImage_t             *destinations,
    cudaStream_t              stream);
