Chapter 1. Introduction

NVIDIA® TensorRT™ is an SDK that facilitates high-performance machine learning inference. It is designed to work in a complementary fashion with training frameworks such as TensorFlow, PyTorch, and MXNet. It focuses specifically on running an already-trained network quickly and efficiently on NVIDIA hardware.

Refer to the NVIDIA TensorRT Installation Guide for instructions on how to install TensorRT.

The NVIDIA TensorRT Quick Start Guide is for users who want to try out TensorRT SDK; specifically, you will learn how to construct an application to run inference on a TensorRT engine quickly.

1.1. Structure of This Guide

Chapter 1 provides information about how TensorRT is packaged and supported, and how it fits into the developer ecosystem.

Chapter 2 provides a broad overview of TensorRT capabilities.

Chapters three and four contain introductions to the C++ and Python APIs respectively.

Subsequent chapters provide more detail about advanced features.

The appendix contains a layer reference and answers to FAQs.

1.2. Samples

The NVIDIA TensorRT Sample Support Guide illustrates many of the topics discussed in this guide. Additional samples focusing on embedded applications can be found here.

1.3. Complementary GPU Features

Multi-Instance GPU, or MIG, is a feature of NVIDIA GPUs with NVIDIA Ampere Architecture or later architectures that enable user-directed partitioning of a single GPU into multiple smaller GPUs. The physical partitions provide dedicated compute and memory slices with QoS and independent execution of parallel workloads on fractions of the GPU. For
TensorRT applications with low GPU utilization, MIG can produce higher throughput at small or no impact on latency. The optimal partitioning scheme is application-specific.

1.4. Complementary Software

The NVIDIA Triton™ Inference Server is a higher-level library providing optimized inference across CPUs and GPUs. It provides capabilities for starting and managing multiple models, and REST and gRPC endpoints for serving inference.

NVIDIA DALI® provides high-performance primitives for preprocessing image, audio, and video data. TensorRT inference can be integrated as a custom operator in a DALI pipeline. A working example of TensorRT inference integrated as a part of DALI can be found here.

TensorFlow-TensorRT (TF-TRT) is an integration of TensorRT directly into TensorFlow. It selects subgraphs of TensorFlow graphs to be accelerated by TensorRT, while leaving the rest of the graph to be executed natively by TensorFlow. The result is still a TensorFlow graph that you can execute as usual. For TF-TRT examples, refer to Examples for TensorRT in TensorFlow.

Torch-TensorRT (Torch-TRT) is a PyTorch-TensorRT compiler that converts PyTorch modules into TensorRT engines. Internally, the PyTorch modules are first converted into TorchScript/FX modules based on the Intermediate Representation (IR) selected. The compiler selects subgraphs of the PyTorch graphs to be accelerated by TensorRT, while leaving the rest of the graph to be executed natively by Torch. The result is still a PyTorch module that you can execute as usual. For examples, refer to Examples for Torch-TRT.

The TensorFlow-Quantization Toolkit provides utilities for training and deploying Tensorflow 2-based Keras models at reduced precision. This toolkit is used to quantize different layers in the graph exclusively based on operator names, class, and pattern matching. The quantized graph can then be converted into ONNX and then into TensorRT engines. For examples, refer to the model zoo.

The PyTorch Quantization Toolkit provides facilities for training PyTorch models at reduced precision, which can then be exported for optimization in TensorRT.

In addition, the PyTorch Automatic SParsity (ASP) tool provides facilities for training models with structured sparsity, which can then be exported and allows TensorRT to use the faster sparse tactics on NVIDIA Ampere Architecture GPUs.

TensorRT is integrated with NVIDIA’s profiling tools, NVIDIA Nsight™ Systems and NVIDIA Deep Learning Profiler (DLProf).

A restricted subset of TensorRT is certified for use in NVIDIA DRIVE® products. Some APIs are marked for use only in NVIDIA DRIVE and are not supported for general use.

1.5. ONNX

TensorRT’s primary means of importing a trained model from a framework is through the ONNX interchange format. TensorRT ships with an ONNX parser library to assist in
importing models. Where possible, the parser is backward compatible up to opset 7; the ONNX Model Opset Version Converter can assist in resolving incompatibilities.

The GitHub version may support later opsets than the version shipped with TensorRT refer to the ONNX-TensorRT operator support matrix for the latest information on the supported opset and operators. For TensorRT deployment, we recommend exporting to the latest available ONNX opset.

The ONNX operator support list for TensorRT can be found here. PyTorch natively supports ONNX export. For TensorFlow, the recommended method is tf2onnx.

A good first step after exporting a model to ONNX is to run constant folding using Polygraphy. This can often solve TensorRT conversion issues in the ONNX parser and generally simplify the workflow. For details, refer to this example. In some cases, it may be necessary to modify the ONNX model further, for example, to replace subgraphs with plugins or reimplement unsupported operations in terms of other operations. To make this process easier, you can use ONNX-GraphSurgeon.

1.6. Code Analysis Tools

For guidance using the valgrind and clang sanitizer tools with TensorRT, refer to the Troubleshooting chapter.

1.7. API Versioning

TensorRT version number (MAJOR.MINOR.PATCH) follows Semantic Versioning 2.0.0 for its public APIs and library ABIs. Version numbers change as follows:

1. MAJOR version when making incompatible API or ABI changes
2. MINOR version when adding functionality in a backward compatible manner
3. PATCH version when making backward compatible bug fixes

Note that semantic versioning does not extend to serialized objects. To reuse plan files, and timing caches, version numbers must match across major, minor, patch, and build versions (with some exceptions for the safety runtime as detailed in the NVIDIA DRIVE OS 6.0 Developer Guide). Calibration caches can typically be reused within a major version but compatibility is not guaranteed.

1.8. Deprecation Policy

Deprecation is used to inform developers that some APIs and tools are no longer recommended for use. Beginning with version 8.0, TensorRT has the following deprecation policy:

- Deprecation notices are communicated in the NVIDIA TensorRT Release Notes.
When using the C++ API:
- API functions are marked with the `TRT_DEPRECATED_API` macro.
- Enums are marked with the `TRT_DEPRECATED_ENUM` macro.
- All other locations are marked with the `TRT_DEPRECATED` macro.
- Classes, functions, and objects will have a statement documenting when they were deprecated.

When using the Python API, deprecated methods and classes will issue deprecation warnings at runtime, if they are used.
- TensorRT provides a 12-month migration period after the deprecation.
- APIs and tools continue to work during the migration period.
- After the migration period ends, APIs and tools are removed in a manner consistent with semantic versioning.

For any APIs and tools specifically deprecated in TensorRT 7.x, the 12-month migration period starts from the TensorRT 8.0 GA release date.

### 1.9. Hardware Support Lifetime

TensorRT 8.5.3 was the last release supporting NVIDIA Kepler (SM 3.x) and NVIDIA Maxwell (SM 5.x) devices. These devices are no longer supported in TensorRT 8.6. NVIDIA Pascal (SM 6.x) devices are deprecated in TensorRT 8.6.

### 1.10. Support

Support, resources, and information about TensorRT can be found online at [https://developer.nvidia.com/tensorrt](https://developer.nvidia.com/tensorrt). This includes blogs, samples, and more.

In addition, you can access the NVIDIA DevTalk TensorRT forum at [https://devtalk.nvidia.com/default/board/304/tensorrt/](https://devtalk.nvidia.com/default/board/304/tensorrt/) for all things related to TensorRT. This forum offers the possibility of finding answers, making connections, and getting involved in discussions with customers, developers, and TensorRT engineers.

### 1.11. Reporting Bugs

NVIDIA appreciates all types of feedback. If you encounter any problems, follow the instructions in the [Reporting TensorRT Issues](#) section to report the issues.
Chapter 2. TensorRT’s Capabilities

This chapter provides an overview of what you can do with TensorRT. It is intended to be useful to all TensorRT users.

2.1. C++ and Python APIs

TensorRT’s API has language bindings for both C++ and Python, with nearly identical capabilities. The Python API facilitates interoperability with Python data processing toolkits and libraries like NumPy and SciPy. The C++ API can be more efficient, and may better meet some compliance requirements, for example in automotive applications.

Note: The Python API is not available for all platforms. For more information, refer to the NVIDIA TensorRT Support Matrix.

2.2. The Programming Model

TensorRT operates in two phases. In the first phase, usually performed offline, you provide TensorRT with a model definition, and TensorRT optimizes it for a target GPU. In the second phase, you use the optimized model to run inference.

2.2.1. The Build Phase

The highest-level interface for the build phase of TensorRT is the Builder (C++, Python). The builder is responsible for optimizing a model, and producing an Engine.

In order to build an engine, you must:

- Create a network definition.
- Specify a configuration for the builder.
- Call the builder to create the engine.

The NetworkDefinition interface (C++, Python) is used to define the model. The most common path to transfer a model to TensorRT is to export it from a framework in ONNX format, and use TensorRT’s ONNX parser to populate the network definition. However,
you can also construct the definition step by step using TensorRT’s Layer (C++, Python) and Tensor (C++, Python) interfaces.

Whichever way you choose, you must also define which tensors are the inputs and outputs of the network. Tensors that are not marked as outputs are considered to be transient values that can be optimized away by the builder. Input and output tensors must be named, so that at runtime, TensorRT knows how to bind the input and output buffers to the model.

The BuilderConfig interface (C++, Python) is used to specify how TensorRT should optimize the model. Among the configuration options available, you can control TensorRT’s ability to reduce the precision of calculations, control the tradeoff between memory and runtime execution speed, and constrain the choice of CUDA® kernels.

Since the builder can take minutes or more to run, you can also control how the builder searches for kernels, and cached search results for use in subsequent runs.

After you have a network definition and a builder configuration, you can call the builder to create the engine. The builder eliminates dead computations, folds constants, and reorders and combines operations to run more efficiently on the GPU. It can optionally reduce the precision of floating-point computations, either by simply running them in 16-bit floating point, or by quantizing floating point values so that calculations can be performed using 8-bit integers. It also times multiple implementations of each layer with varying data formats, then computes an optimal schedule to execute the model, minimizing the combined cost of kernel executions and format transforms.

The builder creates the engine in a serialized form called a plan, which can be deserialized immediately, or saved to disk for later use.

Note:
- By default, engines created by TensorRT are specific to both the TensorRT version with which they were created and the GPU on which they were created. Refer to the Version Compatibility and Hardware Compatibility sections for how to configure an engine for forward compatibility.
- TensorRT’s network definition does not deep-copy parameter arrays (such as the weights for a convolution). Therefore, you must not release the memory for those arrays until the build phase is complete. When importing a network using the ONNX parser, the parser owns the weights, so it must not be destroyed until the build phase is complete.
- The builder times algorithms to determine the fastest. Running the builder in parallel with other GPU work may perturb the timings, resulting in poor optimization.

2.2.2. The Runtime Phase
The highest-level interface for the execution phase of TensorRT is the Runtime (C++, Python).

When using the runtime, you will typically carry out the following steps:
- Deserialize a plan to create an engine.
- Create an execution context from the engine.
Then, repeatedly:

- Populate input buffers for inference.
- Call `enqueueV3()` on the execution context to run inference.

The *Engine* interface (*C++*, *Python*) represents an optimized model. You can query an engine for information about the input and output tensors of the network - the expected dimensions, data type, data format, and so on.

The *ExecutionContext* interface (*C++*, *Python*), created from the engine is the main interface for invoking inference. The execution context contains all of the state associated with a particular invocation - thus you can have multiple contexts associated with a single engine, and run them in parallel.

When invoking inference, you must set up the input and output buffers in the appropriate locations. Depending on the nature of the data, this may be in either CPU or GPU memory. If not obvious based on your model, you can query the engine to determine in which memory space to provide the buffer.

After the buffers are set up, inference can be enqueued (`enqueueV3`). The required kernels are enqueued on a CUDA stream, and control is returned to the application as soon as possible. Some networks require multiple control transfers between CPU and GPU, so control may not return immediately. To wait for completion of asynchronous execution, synchronize on the stream using `cudaStreamSynchronize`.

### 2.3. Plugins

TensorRT has a *Plugin* interface to allow applications to provide implementations of operations that TensorRT does not support natively. Plugins that are created and registered with TensorRT’s PluginRegistry can be found by the ONNX parser while translating the network.

TensorRT ships with a library of plugins, and source for many of these and some additional plugins can be found [here](#).

You can also write your own plugin library and serialize it with the engine.

Refer to the [Extending TensorRT with Custom Layers](#) chapter for more details.

### 2.4. Types and Precision

TensorRT supports FP32, FP16, INT8, INT32, UINT8, and BOOL data types.\(^1\)

Refer to the [TensorRT Operator documentation](#) for layer I/O data type specification.

- FP32, FP16

---

\(^1\) TensorRT 8.6 adds `nvinfer1::DataType::kFP8` to the public API in preparation for the introduction of FP8 support in future TensorRT releases. However, FP8 (8-bit floating point) is not supported by TensorRT currently and attempting to use FP8 will result in an error or undefined behavior.
TensorRT’s Capabilities

- Unquantized higher precision types.
- **INT8**
  - Implicit quantization
    - Interpreted as quantized integer type. A tensor with INT8 type must have an associated scale factor (either through calibration or `setDynamicRange` API).
  - Explicit quantization
    - Interpreted as signed integer type. Conversion to/from INT8 type requires an explicit Q/DQ layer.
- **UINT8**
  - Data type only usable as a network I/O type.
  - Network level inputs in UINT8 must be converted from UINT8 to either FP32 or FP16 using a `CastLayer` before the data is used in other operations.
  - Network-level outputs in UINT8 must be produced by a `CastLayer` that has been explicitly inserted into the network (will only support conversions from FP32/FP16 to UINT8).
  - UINT8 quantization is not supported.
  - The `ConstantLayer` does not support UINT8 as an output type.
- **BOOL**
  - A boolean type used with supported layers.

When TensorRT chooses CUDA kernels to implement floating point operations in the network, it defaults to FP32 implementations. There are two ways to configure different levels of precision:

- To control precision at the model level, `BuilderFlag` options (C++, Python) can indicate to TensorRT that it may select lower-precision implementations when searching for the fastest (and because lower precision is generally faster, if allowed to, it typically will).

  Therefore, you can easily instruct TensorRT to use FP16 calculations for your entire model. For regularized models whose input dynamic range is approximately one, this typically produces significant speedups with negligible change in accuracy.

- For finer-grained control, where a layer must run at higher precision because part of the network is numerically sensitive or requires high dynamic range, arithmetic precision can be specified for that layer.

Refer to the Reduced Precision section for more details.

### 2.5. Quantization

TensorRT supports quantized floating point, where floating-point values are linearly compressed and rounded to 8-bit integers. This significantly increases arithmetic throughput while reducing storage requirements and memory bandwidth. When
quantizing a floating-point tensor, TensorRT must know its dynamic range - that is, what range of values is important to represent - values outside this range are clamped when quantizing.

Dynamic range information can be calculated by the builder (this is called calibration) based on representative input data. Or you can perform quantization-aware training in a framework and import the model to TensorRT with the necessary dynamic range information.

Refer to the Working with INT8 chapter for more details.

2.6. Tensors and Data Formats

When defining a network, TensorRT assumes that tensors are represented by multidimensional C-style arrays. Each layer has a specific interpretation of its inputs: for example, a 2D convolution will assume that the last three dimensions of its input are in CHW format - there is no option to use, for example a WHC format. Refer to NVIDIA TensorRT Operator’s Reference for how each layer interprets its inputs.

Note that tensors are limited to at most 2^31-1 elements.

While optimizing the network, TensorRT performs transformations internally (including to HWC, but also more complex formats) to use the fastest possible CUDA kernels. In general, formats are chosen to optimize performance, and applications have no control over the choices. However, the underlying data formats are exposed at I/O boundaries (network input and output, and passing data to and from plugins) to allow applications to minimize unnecessary format transformations.

Refer to the I/O Formats section for more details.

2.7. Dynamic Shapes

By default, TensorRT optimizes the model based on the input shapes (batch size, image size, and so on) at which it was defined. However, the builder can be configured to allow the input dimensions to be adjusted at runtime. In order to enable this, you specify one or more instances of OptimizationProfile (C++, Python) in the builder configuration, containing for each input a minimum and maximum shape, along with an optimization point within that range.

TensorRT creates an optimized engine for each profile, choosing CUDA kernels that work for all shapes within the [minimum, maximum] range and are fastest for the optimization point - typically different kernels for each profile. You can then select among profiles at runtime.

Refer to the Working with Dynamic Shapes chapter for more details.
2.8. **DLA**

TensorRT supports NVIDIA’s Deep Learning Accelerator (DLA), a dedicated inference processor present on many NVIDIA SoCs that supports a subset of TensorRT’s layers. TensorRT allows you to execute part of the network on the DLA and the rest on GPU; for layers that can be executed on either device, you can select the target device in the builder configuration on a per-layer basis.

Refer to the [Working with DLA](#) chapter for more details.

2.9. **Updating Weights**

When building an engine, you can specify that it may later have its weights updated. This can be useful if you are frequently updating the weights of the model without changing the structure, such as in reinforcement learning or when retraining a model while retaining the same structure. Weight updates are performed using the Refitter (C++, Python) interface.

Refer to the [Refitting an Engine](#) section for more details.

2.10. **trtexec Tool**

Included in the samples directory is a command-line wrapper tool called trtexec. trtexec is a tool to use TensorRT without having to develop your own application. The trtexec tool has three main purposes:

- *benchmarking networks* on random or user-provided input data.
- *generating serialized engines* from models.
- *generating a serialized timing cache* from the builder.

Refer to the [trtexec](#) section for more details.

2.11. **Polygraphy**

Polygraphy is a toolkit designed to assist in running and debugging deep learning models in TensorRT and other frameworks. It includes a Python API and a command-line interface (CLI) built using this API.

Among other things, with Polygraphy you can:

- Run inference among multiple backends, like TensorRT and ONNX-Runtime, and compare results (for example API, CLI).
- Convert models to various formats, for example, TensorRT engines with post-training quantization (for example API, CLI).
- View information about various types of models (for example [CLI]).
- Modify ONNX models on the command line:
  - Extract subgraphs (for example [CLI]).
  - Simplify and sanitize (for example [CLI]).
- Isolate faulty tactics in TensorRT (for example [CLI]).

For more details, refer to the [Polygraphy repository](https://github.com/NVIDIA/polygraphy).
Chapter 3. The C++ API

This chapter illustrates basic usage of the C++ API, assuming you are starting with an ONNX model. `sampleOnnxMNIST` illustrates this use case in more detail.

The C++ API can be accessed through the header `NvInfer.h`, and is in the `nvinfer1` namespace. For example, a simple application might begin with:

```cpp
#include "NvInfer.h"

using namespace nvinfer1;
```

Interface classes in the TensorRT C++ API begin with the prefix `I`, for example `ILogger`, `IBuilder`, and so on.

A CUDA context is automatically created the first time TensorRT makes a call to CUDA, if none exists before that point. It is generally preferable to create and configure the CUDA context yourself before the first call to TensorRT.

In order to illustrate object lifetimes, code in this chapter does not use smart pointers; however, their use is recommended with TensorRT interfaces.

### 3.1. The Build Phase

To create a builder, you first must instantiate the `ILogger` interface. This example captures all warning messages but ignores informational messages:

```cpp
class Logger : public ILogger
{
    void log(Severity severity, const char* msg) noexcept override
    {
        // suppress info-level messages
        if (severity <= Severity::kWARNING)
            std::cout << msg << std::endl;
    }
}
```

You can then create an instance of the builder:

```cpp
IBuilder* builder = createInferBuilder(logger);
```

### 3.1.1. Creating a Network Definition

After the builder has been created, the first step in optimizing a model is to create a network definition:

```cpp
uint32_t flag = 1U << static_cast<uint32_t>(NetworkDefinitionCreationFlag::kEXPLICIT_BATCH);
```
The C++ API

INetworkDefinition* network = builder->createNetworkV2(flag);

The `kEXPLICIT_BATCH` flag is required in order to import models using the ONNX parser. Refer to the Explicit Versus Implicit Batch section for more information.

### 3.1.2. Importing a Model Using the ONNX Parser

Now, the network definition must be populated from the ONNX representation. The ONNX parser API is in the file NvOnnxParser.h, and the parser is in the nvonnxparser C++ namespace.

```cpp
#include “NvOnnxParser.h"

using namespace nvonnxparser;

You can create an ONNX parser to populate the network as follows:

```cpp
IParser* parser = createParser(*network, logger);

Then, read the model file and process any errors.

```cpp
parser->parseFromFile(modelFile,
   static_cast<int32_t>(ILogger::Severity::kWARNING));
for (int32_t i = 0; i < parser.getNbErrors(); ++i)
{
  std::cout << parser->getError(i)->desc() << std::endl;
}
```

An important aspect of a TensorRT network definition is that it contains pointers to model weights, which are copied into the optimized engine by the builder. Since the network was created using the parser, the parser owns the memory occupied by the weights, and so the parser object should not be deleted until after the builder has run.

### 3.1.3. Building an Engine

The next step is to create a build configuration specifying how TensorRT should optimize the model.

```cpp
IBuilderConfig* config = builder->createBuilderConfig();

This interface has many properties that you can set in order to control how TensorRT optimizes the network. One important property is the maximum workspace size. Layer implementations often require a temporary workspace, and this parameter limits the maximum size that any layer in the network can use. If insufficient workspace is provided, it is possible that TensorRT will not be able to find an implementation for a layer. By default the workspace is set to the total global memory size of the given device; restrict it when necessary, for example, when multiple engines are to be built on a single device.

```cpp
config->setMemoryPoolLimit(MemoryPoolType::kWORKSPACE, 1U << 20);
```

Once the configuration has been specified, the engine can be built.

```cpp
IHostMemory* serializedModel = builder->buildSerializedNetwork(*network, *config);
```

Since the serialized engine contains the necessary copies of the weights, the parser, network definition, builder configuration and builder are no longer necessary and may be safely deleted:

```cpp
delete parser;
delete network;
delete config;
```
delete builder;

The engine can then be saved to disk, and the buffer into which it was serialized can be deleted.

delete serializedModel

**Note:** Serialized engines are not portable across platforms or TensorRT versions. Engines are specific to the exact GPU model that they were built on (in addition to the platform and the TensorRT version).

Since building engines is intended as an offline process, it can take significant time. Refer to the [Optimizing Builder Performance](#) section for how to make the builder run faster.

### 3.2. Deserializing a Plan

Assuming you have previously serialized an optimized model and want to perform inference, you must create an instance of the `Runtime` interface. Like the builder, the runtime requires an instance of the logger:

```cpp
IRuntime* runtime = createInferRuntime(logger);
```

After you have read the model into a buffer, you can deserialized it to obtain an engine:

```cpp
ICudaEngine* engine = 
    runtime->deserializeCudaEngine(modelData, modelSize);
```

### 3.3. Performing Inference

The engine holds the optimized model, but to perform inference we must manage additional state for intermediate activations. This is done using the `ExecutionContext` interface:

```cpp
IExecutionContext *context = engine->createExecutionContext();
```

An engine can have multiple execution contexts, allowing one set of weights to be used for multiple overlapping inference tasks. (A current exception to this is when using dynamic shapes, when each optimization profile can only have one execution context, unless the preview feature, `kPROFILE_SHARING_0806`, is specified.)

To perform inference, you must pass TensorRT buffers for input and output, which TensorRT requires you to specify with calls to `setTensorAddress`, which takes the name of the tensor and the address of the buffer. You can query the engine using the names you provided for input and output tensors to find the right positions in the array:

```cpp
context->setTensorAddress(INPUT_NAME, inputBuffer);
context->setTensorAddress(OUTPUT_NAME, outputBuffer);
```

You can then call TensorRT’s method `enqueueV3` to start inference using a CUDA stream:

```cpp
context->enqueueV3(stream);
```

A network will be executed asynchronously or not depending on the structure and features of the network. A non-exhaustive list of features that can cause synchronous behavior are data dependent shapes, DLA usage, loops, and plugins that are synchronous,
for example. It is common to enqueue data transfers with `cudaMemcpyAsync()` before and after the kernels to move data from the GPU if it is not already there.

To determine when the kernels (and possibly `cudaMemcpyAsync()`) are complete, use standard CUDA synchronization mechanisms such as events or waiting on the stream.
Chapter 4. The Python API

This chapter illustrates basic usage of the Python API, assuming you are starting with an ONNX model. The `onnx_resnet50.py` sample illustrates this use case in more detail.

The Python API can be accessed through the `tensorrt` module:

```python
import tensorrt as trt
```

### 4.1. The Build Phase

To create a builder, you must first create a logger. The Python bindings include a simple logger implementation that logs all messages preceding a certain severity to `stdout`.

```python
logger = trt.Logger(trt.Logger.WARNING)
```

Alternatively, it is possible to define your own implementation of the logger by deriving from the `ILogger` class:

```python
class MyLogger(trt.ILogger):
    def __init__(self):
        trt.ILogger.__init__(self)

    def log(self, severity, msg):
        pass # Your custom logging implementation here

logger = MyLogger()
```

You can then create a builder:

```python
builder = trt.Builder(logger)
```

Since building engines is intended as an offline process, it can take significant time. Refer to the Optimizing Builder Performance section for how to make the builder run faster.

#### 4.1.1. Creating a Network Definition in Python

After the builder has been created, the first step in optimizing a model is to create a network definition:

```python
network = builder.create_network(1 << int(trt.NetworkDefinitionCreationFlag.EXPLICIT_BATCH))
```

The `EXPLICIT_BATCH` flag is required in order to import models using the ONNX parser. Refer to the Explicit Versus Implicit Batch section for more information.
4.1.2. Importing a Model Using the ONNX Parser

Now, the network definition must be populated from the ONNX representation. You can create an ONNX parser to populate the network as follows:

```python
t = trt.OnnxParser(network, logger)
```

Then, read the model file and process any errors:

```python
success = parser.parse_from_file(model_path)
for idx in range(parser.num_errors):
    print(parser.get_error(idx))
if not success:
    pass  # Error handling code here
```

4.1.3. Building an Engine

The next step is to create a build configuration specifying how TensorRT should optimize the model:

```python
config = builder.create_builder_config()
```

This interface has many properties that you can set in order to control how TensorRT optimizes the network. One important property is the maximum workspace size. Layer implementations often require a temporary workspace, and this parameter limits the maximum size that any layer in the network can use. If insufficient workspace is provided, it is possible that TensorRT will not be able to find an implementation for a layer. By default, the workspace is set to the total global memory size of the given device; restrict it when necessary, for example, when multiple engines are to be built on a single device.

```python
config.set_memory_pool_limit(trt.MemoryPoolType.WORKSPACE, 1 << 20)  # 1 MiB
```

After the configuration has been specified, the engine can be built and serialized with:

```python
serialized_engine = builder.build_serialized_network(network, config)
```

It may be useful to save the engine to a file for future use. You can do that like so:

```python
with open("sample.engine", "wb") as f:
    f.write(serialized_engine)
```

---

Note: Serialized engines are not portable across platforms or TensorRT versions. Engines are specific to the exact GPU model that they were built on (in addition to the platform and the TensorRT version).

---

4.2. Deserializing a Plan

To perform inference, deserialize the engine using the `Runtime` interface. Like the builder, the runtime requires an instance of the logger.

```python
runtime = trt.Runtime(logger)
```

You can then deserialize the engine from a memory buffer:

```python
engine = runtime.deserialize_cuda_engine(serialized_engine)
```

If you want, first load the engine from a file:
with open("sample.engine", "rb") as f:
    serialized_engine = f.read()

4.3. Performing Inference

The engine holds the optimized model, but to perform inference requires additional state for intermediate activations. This is done using the IExecutionContext interface:

```python
context = engine.create_execution_context()
```

An engine can have multiple execution contexts, allowing one set of weights to be used for multiple overlapping inference tasks. (A current exception to this is when using dynamic shapes, when each optimization profile can only have one execution context, unless the preview feature, PROFILE_SHARING_0806, is specified.)

To perform inference, you must specify buffers for inputs and outputs:

```python
context.set_tensor_address(name, ptr)
```

Several Python packages allow you to allocate memory on the GPU, including, but not limited to, the official CUDA Python bindings, PyTorch, cuPy, and Numba.

After populating the input buffer, you can call TensorRT’s `execute_async_v3` method to start inference using a CUDA stream. A network will be executed asynchronously or not depending on the structure and features of the network. A non-exhaustive list of features that can cause synchronous behavior are data dependent shapes, DLA usage, loops, and plugins that are synchronous, for example.

First, create the CUDA stream. If you already have a CUDA stream, you can use a pointer to the existing stream. For example, for PyTorch CUDA streams, that is, `torch.cuda.Stream()`, you can access the pointer using the `cuda_stream` property; for Polygraphy CUDA streams, use the `ptr` attribute; or you can create a stream using CUDA Python binding directly by calling `cudaStreamCreate()`.

Next, start inference:

```python
context.execute_async_v3(buffers, stream_ptr)
```

It is common to enqueue asynchronous transfers (`cudaMemcpyAsync()`) before and after the kernels to move data from the GPU if it is not already there.

To determine when inference (and asynchronous transfers) are complete, use the standard CUDA synchronization mechanisms such as events or waiting on the stream. For example, with PyTorch CUDA streams or Polygraphy CUDA streams, issue `stream.synchronize()`. With streams created with CUDA Python binding, issue `cudaStreamSynchronize(stream)`. 

```python
```
Chapter 5. How TensorRT Works

This chapter provides more detail on how TensorRT works.

5.1. Object Lifetimes

TensorRT’s API is class-based, with some classes acting as factories for other classes. For objects owned by the user, the lifetime of a factory object must span the lifetime of objects it creates. For example, the NetworkDefinition and BuilderConfig classes are created from the Builder class, and objects of those classes should be destroyed before the builder factory object.

An important exception to this rule is creating an engine from a builder. After you have created an engine, you may destroy the builder, network, parser, and build config and continue using the engine.

5.2. Error Handling and Logging

When creating TensorRT top-level interfaces (builder, runtime or refitter), you must provide an implementation of the Logger (C++, Python) interface. The logger is used for diagnostics and informational messages; its verbosity level is configurable. Since the logger may be used to pass back information at any point in the lifetime of TensorRT, its lifetime must span any use of that interface in your application. The implementation must also be thread-safe, since TensorRT may use worker threads internally.

An API call to an object will use the logger associated with the corresponding top-level interface. For example, in a call to ExecutionContext::enqueueV3(), the execution context was created from an engine, which was created from a runtime, so TensorRT will use the logger associated with that runtime.

The primary method of error handling is the ErrorRecorder (C++, Python) interface. You can implement this interface, and attach it to an API object to receive errors associated with that object. The recorder for an object will also be passed to any others it creates - for example, if you attach an error recorder to an engine, and create an execution context from that engine, it will use the same recorder. If you then attach a new error recorder to the execution context, it will receive only errors coming from that context. If an error is generated but no error recorder is found, it will be emitted through the associated logger.
Note that CUDA errors are generally asynchronous - so when performing multiple inferences or other streams of CUDA work asynchronously in a single CUDA context, an asynchronous GPU error may be observed in a different execution context than the one that generated it.

5.3. Memory

TensorRT uses considerable amounts of device memory, (that is, memory directly accessible by the GPU, as opposed to the host memory attached to the CPU). Since device memory is often a constrained resource, it is important to understand how TensorRT uses it.

5.3.1. The Build Phase

During build, TensorRT allocates device memory for timing layer implementations. Some implementations can consume a large amount of temporary memory, especially with large tensors. You can control the maximum amount of temporary memory through the memory pool limits of the builder config. The workspace size defaults to the full size of device global memory but can be restricted when necessary. If the builder finds applicable kernels that could not be run because of insufficient workspace, it will emit a logging message indicating this.

Even with relatively little workspace however, timing requires creating buffers for input, output, and weights. TensorRT is robust against the operating system (OS) returning out-of-memory for such allocations. On some platforms the OS may successfully provide memory, which then the out-of-memory killer process observes that the system is low on memory, and kills TensorRT. If this happens free up as much system memory as possible before retrying.

During the build phase, there will typically be at least two copies of the weights in host memory: those from the original network, and those included as part of the engine as it is built. In addition, when TensorRT combines weights (for example convolution with batch normalization) additional temporary weight tensors will be created.

5.3.2. The Runtime Phase

At runtime, TensorRT uses relatively little host memory, but can use considerable amounts of device memory.

An engine, on deserialization, allocates device memory to store the model weights. Since the serialized engine is almost all weights, its size is a good approximation to the amount of device memory the weights require.

An ExecutionContext uses two kinds of device memory:

- Persistent memory required by some layer implementations - for example, some convolution implementations use edge masks, and this state cannot be shared between contexts as weights are, because its size depends on the layer input shape, which may vary across contexts. This memory is allocated on creation of the execution context, and lasts for its lifetime.
Scratch memory, used to hold intermediate results while processing the network. This memory is used for intermediate activation tensors. It is also used for temporary storage required by layer implementations, the bound for which is controlled by IBuilderConfig::setMemoryPoolLimit().

You may optionally create an execution context without scratch memory using ICudaEngine::createExecutionContextWithoutDeviceMemory() and provide that memory yourself for the duration of network execution. This allows you to share it between multiple contexts that are not running concurrently, or for other uses while inference is not running. The amount of scratch memory required is returned by ICudaEngine::getDeviceMemorySize().

Information about the amount of persistent memory and scratch memory used by the execution context is emitted by the builder when building the network, at severity kINFO. Examining the log, the messages look similar to the following:

```
[08/12/2021-17:39:11] [I] [TRT] Total Host Persistent Memory: 106528
[08/12/2021-17:39:11] [I] [TRT] Total Device Persistent Memory: 29785600
[08/12/2021-17:39:11] [I] [TRT] Total Scratch Memory: 9970688
```

By default, TensorRT allocates device memory directly from CUDA. However, you can attach an implementation of TensorRT’s IGpuAllocator (C++, Python) interface to the builder or runtime and manage device memory yourself. This is useful if your application wants to control all GPU memory and suballocate to TensorRT instead of having TensorRT allocate directly from CUDA.

TensorRT’s dependencies (NVIDIA cuDNN and NVIDIA cuBLAS) can occupy large amounts of device memory. TensorRT allows you to control whether these libraries are used for inference by using the TacticSources (C++, Python) attribute in the builder configuration. Note that some plugin implementations require these libraries, so that when they are excluded, the network may not be compiled successfully.

In addition, PreviewFeature::kDISABLE_EXTERNAL_TACTIC_SOURCES_FOR_CORE_0805 is used to control the usage of cuDNN, cuBLAS, and cuBLASLt in the TensorRT core library. When this flag is set, the TensorRT core library will not use these tactics even if they are specified by IBuilderConfig::setTacticSources(). This flag will not affect the cudnnContext and cublasContext handles passed to the plugins using IPluginV2Ext::attachToContext() if the appropriate tactic sources are set. This flag is set by default.

The CUDA infrastructure and TensorRT’s device code also consume device memory. The amount of memory varies by platform, device, and TensorRT version. You can use cudaGetMemInfo to determine the total amount of device memory in use.

TensorRT measures the amount of memory in use before and after critical operations in builder and runtime. These memory usage statistics are printed to TensorRT’s information logger. For example:

```
[MemUsageChange] Init CUDA: CPU +535, GPU +0, now: CPU 547, GPU 1293 (MiB)
```
It indicates the memory use change by CUDA initialization. CPU +535, GPU +0 is the increased amount of memory after running CUDA initialization. The content after now is the CPU/GPU memory usage snapshot after CUDA initialization.

Note: In a multi-tenant situation, the reported memory use by cudaGetMemInfo and TensorRT is prone to race conditions where a new allocation/free done by a different process or a different thread. Since CUDA is not in control of memory on unified-memory devices, the results returned by cudaGetMemInfo may not be accurate on these platforms.

5.3.3. CUDA Lazy Loading

CUDA lazy loading is a CUDA feature that can significantly reduce the peak GPU and host memory usage of TensorRT and speed up TensorRT initialization with negligible (< 1%) performance impact. The saving of memory usage and initialization time depends on the model, software stack, GPU platform, etc. It is enabled by setting the environment variable CUDA_MODULE_LOADING=LAZY. Refer to the NVIDIA CUDA documentation for more information.

5.3.4. L2 Persistent Cache Management

NVIDIA Ampere and later architectures support L2 cache persistence, a feature which allows prioritization of L2 cache lines for retention when a line is chosen for eviction. TensorRT can use this to retain activations in cache, reducing DRAM traffic, and power consumption.

Cache allocation is per-execution context, enabled using the context’s setPersistentCacheLimit method. The total persistent cache among all contexts (and other components using this feature) should not exceed cudaDeviceProp::persistingL2CacheMaxSize. Refer to the NVIDIA CUDA Best Practices Guide for more information.

5.4. Threading

In general, TensorRT objects are not thread safe; accesses to an object from different threads must be serialized by the client.

The expected runtime concurrency model is that different threads will operate on different execution contexts. The context contains the state of the network (activation values, and so on) during execution, so using a context concurrently in different threads results in undefined behavior.

To support this model, the following operations are thread safe:

- Nonmodifying operations on a runtime or engine.
- Deserializing an engine from a TensorRT runtime.
- Creating an execution context from an engine.
- Registering and deregistering plugins.
There are no thread-safety issues with using multiple builders in different threads; however, the builder uses timing to determine the fastest kernel for the parameters provided, and using multiple builders with the same GPU will perturb the timing and TensorRT's ability to construct optimal engines. There are no such issues using multiple threads to build with different GPUs.

5.5. Determinism

The TensorRT builder uses timing to find the fastest kernel to implement a given operator. Timing kernels is subject to noise - other work running on the GPU, fluctuations in GPU clock speed, and so on. Timing noise means that on successive runs of the builder, the same implementation may not be selected.

In general, different implementations will use a different order of floating point operations, resulting in small differences in the output. The impact of these differences on the final result is usually very small. However, when TensorRT is configured to optimize by tuning over multiple precisions, the difference between an FP16 and an FP32 kernel can be more significant, particularly if the network has not been well regularized or is otherwise sensitive to numerical drift.

Other configuration options that can result in a different kernel selection are different input sizes (for example, batch size) or a different optimization point for an input profile (refer to the Working with Dynamic Shapes section).

The AlgorithmSelector (C++, Python) interface allows you to force the builder to pick a particular implementation for a given layer. You can use this to ensure that the same kernels are picked by the builder from run to run. For more information, refer to the Algorithm Selection and Reproducible Builds section.

After an engine has been built, except for IFillLayer, it is deterministic: providing the same input in the same runtime environment will produce the same output.

5.5.1. IFillLayer Determinism

When IFillLayer is added to a network using either the RANDOM_UNIFORM or RANDOM_NORMAL operations, the determinism guarantee above is no longer valid. On each invocation, these operations generate tensors based on the RNG state, and then update the RNG state. This state is stored on a per-execution context basis.

5.6. Runtime Options

TensorRT provides multiple runtime libraries to meet a variety of use cases. C++ applications that run TensorRT engines should link against one of the following:

- The default runtime is the main library (libnvinfer.so/.dll).
- The lean runtime library (libnvinfer_lean.so/.dll) is much smaller than the default library, and contains only the code necessary to run a version-compatible engine. It has some restrictions; primarily, it cannot refit or serialize engines.
The dispatch runtime (libnvinfer_dispatch.so/.dll) is a small shim library that can load a lean runtime, and redirect calls to it. The dispatch runtime is capable of loading older versions of the lean runtime, and together with appropriate configuration of the builder, can be used to provide compatibility between a newer version of TensorRT and an older plan file. Using the dispatch runtime is almost the same as manually loading the lean runtime, but it checks that APIs are implemented by the lean runtime loaded, and performs some parameter mapping to support API changes where possible.

The lean runtime contains fewer operator implementations than the default runtime. Since TensorRT chooses operator implementations at build time, you need to specify that the engine should be built for the lean runtime by enabling version compatibility. It may be slightly slower than an engine built for the default runtime.

The lean runtime contains all the functionality of the dispatch runtime, and the default runtime contains all the functionality of the lean runtime.

TensorRT provides Python packages corresponding to each of the above libraries:

- **tensorrt**
  - A Python package. It is the Python interface for the default runtime.
- **tensorrt_lean**
  - A Python package. It is the Python interface for the lean runtime.
- **tensorrt_dispatch**
  - A Python package. It is the Python interface for the dispatch runtime.

Python applications that run TensorRT engines should import one of the above packages to load the appropriate library for their use case.

### 5.7. Compatibility

By default, serialized engines are only guaranteed to work correctly when used with the same OS, CPU architectures, GPU models, and TensorRT versions used to serialize the engines. Refer to the Version Compatibility and Hardware Compatibility sections for how to relax the constraints on TensorRT versions and GPU models.
Chapter 6. Advanced Topics

6.1. Version Compatibility

By default, TensorRT engines are compatible only with the version of TensorRT with which they are built. With appropriate build-time configuration, engines can be built that are compatible with other TensorRT minor versions within a major version. TensorRT engines built with TensorRT 8 will also be compatible with TensorRT 9 runtimes, but not vice versa.

Version compatibility is supported from version 8.6; that is, the plan must be built with a version at least 8.6 or higher, and the runtime must be 8.6 or higher.

When using version compatibility, the API supported at runtime for an engine is the intersection of the API supported in the version with which it was built, and the API of the version used to run it. TensorRT removes APIs only on major version boundaries so this is not a concern within a major version. However, users wishing to use TensorRT 8 engines with TensorRT 9 must migrate away from deprecated APIs.

The recommended approach to creating a version-compatible engine is to build as follows:

**C++**

```cpp
builderConfig.setFlag(BuilderFlag::kVERSION_COMPATIBLE);
IHostMemory* plan = builder->buildSerializedNetwork(network, config);
```

**Python**

```python
builder_config.set_flag(tensorrt.BuilderFlag.VERSION_COMPATIBLE)
plan = builder.build_serialized_network(network, config)
```

This flag is not supported with implicit batch mode. The network must be created with `NetworkDefinitionCreationFlag::kEXPLICIT_BATCH`.

This causes a copy of the lean runtime to be added to the plan. When you subsequently deserialize the plan, TensorRT recognizes that it contains a copy of the runtime. It loads the runtime, and uses it to deserialize and execute the rest of the plan. Because this results in code being loaded and run from the plan in the context of the owning process, you should only deserialize trusted plans this way. To indicate to TensorRT that you trust the plan, call:

**C++**

```cpp
runtime->setEngineHostCodeAllowed(true);
```

**Python**

```python
runtime.engine_host_code_allowed = True
```
The flag for trusted plans is also required if you are packaging plugins in the plan (refer to Plugin Shared Libraries).

6.1.1. Manually Loading the Runtime

The previous approach (Version Compatibility) packages a copy of the runtime with every plan, which can be prohibitive if your application uses a large number of models. An alternative approach is to manage the runtime loading yourself. For this approach, build version compatible plans as explained in the previous section, but also set an additional flag to exclude the lean runtime.

C++
```c++
  builderConfig.setFlag(BuilderFlag::kVERSION_COMPATIBLE);
builderConfig.setFlag(BuilderFlag::kEXCLUDELEAN_RUNTIME);
  IHostMemory* plan = builder->buildSerializedNetwork(network, config);
```

Python
```python
  builder_config.set_flag(tensorrt.BuilderFlag.VERSION_COMPATIBLE)
  builder_config.set_flag(tensorrt.BuilderFlag.EXCLUDELEAN_RUNTIME)
  plan = builder.build_serialized_network(network, config)
```

To run this plan, you must have access to the lean runtime for the version with which it was built. Suppose you have built the plan with TensorRT 8.6 and your application is linked against TensorRT 9, you can load the plan as follows.

C++
```c++
  IRuntime* v9Runtime = createInferRuntime(logger);
  IRuntime* v8ShimRuntime = v9Runtime->loadRuntime(v8RuntimePath);
  engine = v8ShimRuntime->deserializeCudaEngine(v8plan);
```

Python
```python
  v9_runtime = tensorrt.Runtime(logger)
  v8_shim_runtime = v9_runtime.load_runtime(v8_runtime_path)
  engine = v8_shim_runtime.deserialize_cuda_engine(v8_plan)
```

The runtime will translate TensorRT 9 API calls for the TensorRT 8.6 runtime, checking to ensure that the call is supported and performing any necessary parameter remapping.

6.1.2. Loading from Storage

On most OSs, TensorRT can load the shared runtime library directly from memory. However, on Linux kernels prior to 3.17, a temporary directory is required. Use the IRuntime::setTempfileControlFlags and IRuntime::setTemporaryDirectory APIs to control TensorRT’s use of these mechanisms.

6.1.3. Using Version Compatibility with the ONNX Parser

When building a version-compatible engine from a TensorRT network definition generated using TensorRT’s ONNX parser, you must specify that the parser must use the native InstanceNormalization implementation instead of the plugin one.

To do this, use the IParser::setFlag() API.

C++
```c++
  auto *parser = nvonnxparser::createParser(network, logger);
  parser->setFlag(nvonnxparser::OnnxParserFlag::kNATIVE_INSTANCENORM);
```
In addition, the parser may require the use of plugins in order to fully implement all ONNX operators used in the network. In particular, if the network is used to build a version-compatible engine, some plugins may need to be included with the engine (either serialized with the engine, or provided externally and loaded explicitly).

To query the list of plugin libraries needed to implement a particular parsed network, use the `IParser::getUsedVCPluginLibraries` API:

```cpp
auto *parser = nvonnxparser::createParser(network, logger);
parser->setFlag(nvonnxparser::OnnxParserFlag::kNATIVE_INSTANCENORM);
parser->parseFromFile(filename, static_cast<int>(ILogger::Severity::kINFO));
int64_t nbPluginLibs;
char const* const* pluginLibs = parser->getUsedVCPluginLibraries(nbPluginLibs);
```

![C++ example](image)

```python
parser = trt.OnnxParser(network, logger)
parser.set_flag(trt.OnnxParserFlag.NATIVE_INSTANCENORM)
status = parser.parse_from_file(filename)
plugin_libs = parser.get_used_vc_plugin_libraries()
```

Refer to [Plugin Shared Libraries](#), for how to use the resulting library list to serialize the plugins or package them externally.

### 6.2. Hardware Compatibility

By default, TensorRT engines are only compatible with the type of device where they were built. With build-time configuration, engines can be built that are compatible with other types of devices. Currently, hardware compatibility is supported only for Ampere and later device architectures and is not supported on NVIDIA DRIVE OS or JetPack.

For example, to build an engine compatible with all Ampere and newer architectures, configure the `IBuilderConfig` as follows:

```cpp
config->setHardwareCompatibilityLevel(nvinfer1::HardwareCompatibilityLevel::kAMPERE_PLUS);
```

When building in hardware compatibility mode, TensorRT excludes tactics that are not hardware compatible, such as those that use architecture-specific instructions or require more shared memory than is available on some devices. Thus, a hardware-compatible engine may have lower throughput and/or higher latency than its non-hardware-compatible counterpart. The degree of this performance impact depends on the network architecture and input sizes.

### 6.3. Compatibility Checks

TensorRT records in a plan the major, minor, patch and build versions of the library used to create the plan. If these do not match the version of the runtime used to deserialize the plan, it will fail to deserialize. When using version compatibility, the check will be performed by the lean runtime deserializing the plan data. By default, that lean runtime is included in the plan, and the match is guaranteed to succeed.
TensorRT also records the compute capability (major and minor versions) in the plan, and checks it against the GPU on which the plan is being loaded. If they do not match, the plan will fail to deserialize. This ensures that kernels selected during the build phase are present and can run. When using hardware compatibility, the check is relaxed; with `HardwareCompatibilityLevel::kAMPERE_PLUS`, the check will ensure that the compute capability is greater than or equal to 8.0 rather than checking for an exact match.

TensorRT additionally checks the following properties and will issue a warning if they do not match, except when using hardware compatibility:

- Global memory bus width
- L2 cache size
- Maximum shared memory per block and per multiprocessor
- Texture alignment requirement
- Number of multiprocessors
- Whether the GPU device is integrated or discrete

If GPU clock speeds differ between engine serialization and runtime systems, the chosen tactics from the serialization system may not be optimal for the runtime system and may incur some performance degradation.

If the device memory available during deserialization is smaller than the amount during serialization, deserialization may fail due to memory allocation failures.

If optimizing a single TensorRT engine for use on multiple devices in the same architecture, the recommended approach is to run the builder on the smallest device. Alternatively, you can build the engine on the larger device with limited compute resources (refer to the Limiting Compute Resources section). This is because when building small models on large devices, TensorRT may choose kernels that are less efficient but scale better across the available resources. In addition, the APIs that TensorRT uses to select and configure kernels from cuDNN and cuBLAS do not support cross-device compatibility, so disable the use of these tactic sources in the builder configuration.

The safety runtime is able to deserialize engines generated in an environment where the major, minor, patch, and build version of TensorRT does not match exactly in some cases. Refer to the NVIDIA DRIVE OS 6.0 Developer Guide for more information.

6.4. Refitting an Engine

TensorRT can refit an engine with new weights without having to rebuild it, however, the option to do so must be specified when building:

```
config->setFlag(BuilderFlag::kREFIT)
built->buildSerializedNetwork(network, config);
```

Later, you can create a Refitter object:

```
ICudaEngine* engine = ...;
IRefitter* refitter = createInferRefitter(*engine, gLogger)
```
Then update the weights. For example, to update the kernel weights for a convolution layer named "MyLayer":

```cpp
Weights newWeights = ...;
refitter->setWeights("MyLayer", WeightsRole::kKERNEL,
                      newWeights);
```

The new weights should have the same count as the original weights used to build the engine. `setWeights` returns false if something went wrong, such as a wrong layer name or role or a change in the weights count.

Because of the way the engine is optimized, if you change some weights, you might have to supply some other weights too. The interface can tell you what additional weights must be supplied.

You can use `INetworkDefinition::setWeightsName()` to name weights at build time - the ONNX parser uses this API to associate the weights with the names used in the ONNX model. Then, later you can use `setNamedWeights` to update the weights:

```cpp
Weights newWeights = ...;
refitter->setNamedWeights("MyWeights", newWeights);
```

`setNamedWeights` and `setWeights` can be used at the same time, that is, you can update weights with names using `setNamedWeights` and update those unnamed weights using `setWeights`.

This typically requires two calls to `IRefitter::getMissing`, first to get the number of weights objects that must be supplied, and second to get their layers and roles.

```cpp
const int32_t n = refitter->getMissing(0, nullptr, nullptr);
std::vector<const char*> layerNames(n);
std::vector<WeightsRole> weightsRoles(n);
refitter->getMissing(n, layerNames.data(),
                     weightsRoles.data());
```

Alternatively, to get the names of all missing weights, run:

```cpp
const int32_t n = refitter->getMissingWeights(0, nullptr);
std::vector<const char*> weightsNames(n);
refitter->getMissingWeights(n, weightsNames.data());
```

You can supply the missing weights, in any order:

```cpp
for (int32_t i = 0; i < n; ++i)
    refitter->setWeights(layerNames[i], weightsRoles[i],
                         Weights{...});
```

The set of missing weights returned is complete, in the sense that supplying only the missing weights does not generate a need for any more weights.

Once all the weights have been provided, you can update the engine:

```cpp
bool success = refitter->refitCudaEngine();
assert(success);
```

If refit returns false, check the log for a diagnostic, perhaps about weights that are still missing.

You can then delete the refitter:

```cpp
delete refitter;
```
The updated engine behaves as if it had been built from a network updated with the new weights.

To view all refittable weights in an engine, use `refitter->getAll(...)` or `refitter->getAllWeights(...);` similarly to how `getMissing` and `getMissingWeights` were used previously.

### 6.5. Algorithm Selection and Reproducible Builds

The default behavior of TensorRT’s optimizer is to choose the algorithms that globally minimize the execution time of the engine. It does this by timing each implementation, and sometimes, and when implementations have similar timings, it is possible that system noise will determine which will be chosen on any particular run of the builder. Different implementations will typically use different order of accumulation of floating point values, and two implementations may use different algorithms or even run at different precisions. Thus, different invocations of the builder will typically not result in engines that return bit-identical results.

Sometimes it is important to have a deterministic build, or to recreate the algorithm choices of an earlier build. By providing an implementation of the `IAlgorithmSelector` interface and attaching it to a builder configuration with `setAlgorithmSelector`, you can guide algorithm selection manually.

The method `IAlgorithmSelector::selectAlgorithms` receives an `AlgorithmContext` containing information about the algorithm requirements for a layer, and a set of `Algorithm` choices meeting those requirements. It returns the set of algorithms which TensorRT should consider for the layer.

The builder selects from these algorithms the one that minimizes the global runtime for the network. If no choice is returned and `BuilderFlag::kREJECT_EMPTY_ALGORITHMS` is unset, TensorRT interprets this to mean that any algorithm may be used for this layer. To override this behavior and generate an error if an empty list is returned, set the `BuilderFlag::kREJECT_EMPTY_ALGORITHMS` flag.

After TensorRT has finished optimizing the network for a given profile, it calls `reportAlgorithms`, which can be used to record the final choice made for each layer.

To build a TensorRT engine deterministically, return a single choice from `selectAlgorithms`. To replay choices from an earlier build, use `reportAlgorithms` to record the choices in that build, and return them in `selectAlgorithms`.

`sampleAlgorithmSelector` demonstrates how to use the algorithm selector to achieve determinism and reproducibility in the builder.

---

**Note:**
The notion of a "layer" in algorithm selection is different from ILayer in INetworkDefinition. The "layer" in the former can be equivalent to a collection of multiple network layers due to fusion optimizations.

Picking the fastest algorithm in selectAlgorithms may not produce the best performance for the overall network, as it may increase reformatting overhead.

The timing of an IAlgorithm is 0 in selectAlgorithms if TensorRT found that layer to be a no-op.

reportAlgorithms does not provide the timing and workspace information for an IAlgorithm that are provided to selectAlgorithms.

### 6.6. Creating a Network Definition from Scratch

Instead of using a parser, you can also define the network directly to TensorRT using the Network Definition API. This scenario assumes that the per-layer weights are ready in host memory to pass to TensorRT during the network creation.

The following examples create a simple network with Input, Convolution, Pooling, MatrixMultiply, Shuffle, Activation, and SoftMax layers.

For more information regarding layers, refer to the NVIDIA TensorRT Operator's Reference.

#### 6.6.1. C++

In this example, the weights are loaded into a weightMap data structure used in the following code.

First create the builder and network objects. Note that in the following example, the logger is initialized using the logger.cpp file common to all C++ samples. The C++ sample helper classes and functions can be found in the common.h header file.

```cpp
auto builder = SampleUniquePtr<nvinfer1::IBuilder>(nvinfer1::createInferBuilder(sample::gLogger.getTRTLogger()));
const auto explicitBatchFlag = 1U << static_cast<uint32_t>(nvinfer1::NetworkDefinitionCreationFlag::kEXPLICIT_BATCH);
auto network = SampleUniquePtr<nvinfer1::INetworkDefinition>(builder->createNetworkV2(explicitBatchFlag));
```

Refer to the Explicit Versus Implicit Batch section for more information about the kEXPLICIT_BATCH flag.

Add the Input layer to the network by specifying the name, datatype, and full dimensions of the input tensor. A network can have multiple inputs, although in this sample there is only one:

```cpp
auto data = network->addInput(INPUT_BLOB_NAME, datatype, Dims4{1, 1, INPUT_H, INPUT_W});
```

Add the Convolution layer with hidden layer input nodes, strides, and weights for filter and bias.

```cpp
auto conv1 = network->addConvolution(*data->getOutput(0), 20, DimsHW{5, 5}, weightMap["conv1filter"], weightMap["conv1bias"]);
```
conv1->setStride(DimsHW\{1, 1\});

**Note:** Weights passed to TensorRT layers are in host memory.

Add the Pooling layer; note that the output from the previous layer is passed as input.

```c++
auto pool1 = network->addPooling(*conv1->getOutput(0), PoolingType::kMAX, DimsHW\{2, 2\});
pool1->setStride(DimsHW\{2, 2\});
```

Add a Shuffle layer to reshape the input in preparation for a matrix multiplication:

```c++
int32_t const batch = input->getDimensions().d[0];
int32_t const mmInputs = input.getDimensions().d[1] * input.getDimensions().d[2] * input.getDimensions().d[3];
auto inputReshape = network->addShuffle(*input);
inputReshape->setReshapeDimensions(Dims\{2, \{batch, mmInputs\}\});
```

Now, add a MatrixMultiply layer. Here, the model exporter provided transposed weights, so the `kTRANSPOSE` option is specified for those.

```c++
IConstantLayer* filterConst = network->addConstant(Dims\{2, \{nbOutputs, mmInputs\}\}, mWeightMap["ip1filter"]);
auto mm = network->addMatrixMultiply(*inputReshape->getOutput(0), MatrixOperation::kNONE, *filterConst->getOutput(0), MatrixOperation::kTRANSPOSE);
```

Add the bias, which will broadcast across the batch dimension.

```c++
auto biasConst = network->addConstant(Dims\{2, \{1, nbOutputs\}\}, mWeightMap["ip1bias"]);
auto biasAdd = network->addElementWise(*mm->getOutput(0), *biasConst->getOutput(0), ElementWiseOperation::kSUM);
```

Add the ReLU Activation layer:

```c++
auto relu1 = network->addActivation(*ip1->getOutput(0), ActivationType::kRELU);
```

Add the SoftMax layer to calculate the final probabilities:

```c++
auto prob = network->addSoftMax(*relu1->getOutput(0));
```

Add a name for the output of the SoftMax layer so that the tensor can be bound to a memory buffer at inference time:

```c++
prob->getOutput(0)->setName(OUTPUT_BLOB_NAME);
```

Mark it as the output of the entire network:

```c++
network->markOutput(*prob->getOutput(0));
```

The network representing the MNIST model has now been fully constructed. Refer to sections Building an Engine and Deserializing a Plan for how to build an engine and run inference with this network.

### 6.6.2. Python

Code corresponding to this section can be found in `network_api_pytorch_mnist`.

This example uses a helper class to hold some of metadata about the model:

```python
class ModelData(object):
    INPUT_NAME = "data"
    INPUT_SHAPE = (1, 1, 28, 28)
    OUTPUT_NAME = "prob"
    OUTPUT_SIZE = 10
    DTYPE = trt.float32
```

In this example, the weights are imported from the PyTorch MNIST model.

```python
weights = mnist_model.get_weights()
```

Create the logger, builder, and network classes.
TRT_LOGGER = trt.Logger(trt.Logger.ERROR)
builder = trt.Builder(TRT_LOGGER)
EXPLICIT_BATCH = 1 << (int)(trt.NetworkDefinitionCreationFlag.EXPLICIT_BATCH)
network = builder.create_network(EXPLICIT_BATCH)

Refer to the Explicit Versus Implicit Batch section for more information about the kEXPLICIT_BATCH flag.

Next, create the input tensor for the network, specifying the name, datatype, and shape of the tensor.

input_tensor = network.add_input(name=ModelData.INPUT_NAME, dtype=ModelData.DTYPE, shape=ModelData.INPUT_SHAPE)

Add a convolution layer, specifying the inputs, number of output maps, kernel shape, weights, bias, and stride:

\[
\text{conv1} = \text{network.add_convolution}(\text{input}=\text{input_tensor}, \text{num_output_maps}=20, \text{kernel_shape}=(5, 5), \text{bias}=\text{conv1_b})
\]

\[
\text{conv1}.\text{stride} = (1, 1)
\]

Add a pooling layer, specifying the inputs (the output of the previous convolution layer), pooling type, window size, and stride:

\[
\text{pool1} = \text{network.add_pooling}(\text{input}=\text{conv1}.\text{get_output}(0), \text{type}=\text{trt.PoolingType.MAX}, \text{window_size}=(2, 2))
\]

\[
\text{pool1}.\text{stride} = (2, 2)
\]

Add the next pair of convolution and pooling layers:

\[
\text{conv2} = \text{network.add_convolution}(\text{pool1}.\text{get_output}(0), 50, (5, 5), \text{conv2_w}, \text{conv2_b})
\]

\[
\text{conv2}.\text{stride} = (1, 1)
\]

\[
\text{pool2} = \text{network.add_pooling}(\text{conv2}.\text{get_output}(0), \text{trt.PoolingType.MAX}, (2, 2))
\]

\[
\text{pool2}.\text{stride} = (2, 2)
\]

Add a Shuffle layer to reshape the input in preparation for a matrix multiplication:

\[
\text{batch} = \text{input.shape}[0]
\]

\[
\text{mm_inputs} = \text{np.prod}(%s)
\]

\[
\text{input_reshape} = \text{net.add_shuffle}(\text{input})
\]

\[
\text{input_reshape}.\text{reshape_dims} = \text{trt.Dims2}(%s)
\]

Now, add a MatrixMultiply layer. Here, the model exporter provided transposed weights, so the kTRANSPOSE option is specified for those.

\[
\text{filter_const} = \text{net.add_constant}(\text{trt.Dims2}(\text{nbOutputs}, k), \text{weights}[\text{fc1.weight}].\text{numpy}())
\]

\[
\text{mm} = \text{net.add_matrix_multiply}(\text{input_reshape}.\text{get_output}(0), \text{trt.MatrixOperation.NONE}, \text{filter_const}.\text{get_output}(0), \text{trt.MatrixOperation.TRANSPOSE});
\]

Add bias, which will broadcast across the batch dimension:

\[
\text{bias_const} = \text{net.add_constant}(\text{trt.Dims2}(1, \text{nbOutputs}), \text{weights}[\text{fc1.bias}].\text{numpy}())
\]

\[
\text{bias_add} = \text{net.add_elementwise}(\text{mm}.\text{get_output}(0), \text{bias_const}.\text{get_output}(0), \text{trt.ElementWiseOperation.SUM})
\]

Add the ReLU activation layer:

\[
\text{relu1} = \text{network.add_activation}(\text{input}=\text{fc1}.\text{get_output}(0), \text{type}=\text{trt.ACTIVATION_TYPE.RELU})
\]

Add the final fully connected layer, and mark the output of this layer as the output of the entire network:

\[
\text{fc2} = \text{network.add_fully_connected}(\text{relu1}.\text{get_output}(0), \text{ModelData.OUTPUT_SIZE}, \text{fc2_w}, \text{fc2_b})
\]
The network representing the MNIST model has now been fully constructed. Refer to sections Building an Engine and Performing Inference for how to build an engine and run inference with this network.

6.7. Reduced Precision

6.7.1. Network-Level Control of Precision

By default, TensorRT works in 32-bit precision, but can also execute operations using 16-bit floating point, and 8-bit quantized floating point. Using lower precision requires less memory and enables faster computation.

Reduced precision support depends on your hardware (refer to Hardware and Precision). You can query the builder to check the supported precision support on a platform:

C++
```cpp
if (builder->platformHasFastFp16()) {
    ...
}
```

Python
```python
if builder.platform_has_fp16:
```

Setting flags in the builder configuration informs TensorRT that it may select lower-precision implementations:

C++
```cpp
config->setFlag(BuilderFlag::kFP16);
```

Python
```python
config.set_flag(trt.BuilderFlag.FP16)
```

There are three precision flags: FP16, INT8, and TF32, and they may be enabled independently. Note that TensorRT will still choose a higher-precision kernel if it results in overall lower runtime, or if no low-precision implementation exists.

When TensorRT chooses a precision for a layer, it automatically converts weights as necessary to run the layer.

While using FP16 and TF32 precisions is relatively straightforward, there is additional complexity when working with INT8. Refer to the Working with INT8 chapter for more details.

Note that even if the precision flags are enabled, the input/output bindings of the engine defaults to FP32. Refer to the I/O Formats section about how to set the data types and formats of the input/output bindings.

6.7.2. Layer-Level Control of Precision

The builder flags provide permissive, coarse-grained control. However, sometimes part of a network requires higher dynamic range or is sensitive to numerical precision. You can constrain the input and output types per layer:

C++
```cpp
layer->setPrecision(DataType::kFP16)
```
This provides a preferred type (here, `DataType::kFP16`) for the inputs and outputs.

You may further set preferred types for the layer's outputs:

**C++**

```cpp
layer->setOutputType(out_tensor_index, DataType::kFLOAT)
```

**Python**

```python
layer.set_output_type(out_tensor_index, trt.fp32)
```

The computation will use the same floating-point type as is preferred for the inputs. Most TensorRT implementations have the same floating-point types for input and output; however, Convolution, Deconvolution, and FullyConnected can support quantized INT8 input and unquantized FP16 or FP32 output, as sometimes working with higher-precision outputs from quantized inputs is necessary to preserve accuracy.

Setting the precision constraint hints to TensorRT that it should select a layer implementation whose inputs and outputs match the preferred types, inserting reformat operations if the outputs of the previous layer and the inputs to the next layer do not match the requested types. Note that TensorRT will only be able to select an implementation with these types if they are also enabled using the flags in the builder configuration.

By default, TensorRT chooses such an implementation only if it results in a higher-performance network. If another implementation is faster, TensorRT uses it and issues a warning. You can override this behavior by preferring the type constraints in the builder configuration:

**C++**

```cpp
config->setFlag(BuilderFlag::kPREFER_PRECISION_CONSTRAINTS)
```

**Python**

```python
config.set_flag(trt.BuilderFlag.PREFER_PRECISION_CONSTRAINTS)
```

If the constraints are preferred, TensorRT obeys them unless there is no implementation with the preferred precision constraints, in which case it issues a warning and uses the fastest available implementation.

To change the warning to an error, use `OBEY` instead of `PREFER`:

**C++**

```cpp
config->setFlag(BuilderFlag::kOBEY_PRECISION_CONSTRAINTS);
```

**Python**

```python
config.set_flag(trt.BuilderFlag.OBEY_PRECISION_CONSTRAINTS);
```

`samp[leINT8API]` illustrates the use of reduced precision with these APIs.

Precision constraints are optional - you can query to determine whether a constraint has been set using `layer->precisionIsSet()` in C++ or `layer.precision_is_set` in Python. If a precision constraint is not set, then the result returned from `layer->getPrecision()` in C++, or reading the `precision` attribute in Python, is not meaningful. Output type constraints are similarly optional.

If no constraints are set using `ILayer::setPrecision` or `ILayer::setOutputType` API, then `BuilderFlag::kPREFER_PRECISION_CONSTRAINTS` or `BuilderFlag::kOBEY_PRECISION_CONSTRAINTS` are ignored. A layer is free to choose from any precision or output types based on allowed builder precisions.
Note that the `ITensor::setType()` API does not set the precision constraint of a tensor, unless it is one of the input/output tensors of the network. Also, there is a distinction between `layer->setOutputType()` and `layer->getOutput(i)->setType()`. The former, is an optional type that constrains the implementation that TensorRT will choose for a layer. The latter, specifies the type of a networks input/output and is ignored if the tensor is not a network input/output. If they are different, TensorRT will insert a cast to ensure that both specifications are respected. Thus if you are calling `setOutputType()` for a layer that produces a network output, you should in general also configure the corresponding network output to have the same type.

6.7.3. TF32

TensorRT allows the use of TF32 Tensor Cores by default. When computing inner products, such as during convolution or matrix multiplication, TF32 execution does the following:

- Rounds the FP32 multiplicands to FP16 precision but keeps the FP32 dynamic range.
- Computes an exact product of the rounded multiplicands.
- Accumulates the products in an FP32 sum.

TF32 Tensor Cores can speed up networks using FP32, typically with no loss of accuracy. It is more robust than FP16 for models that require an HDR (high dynamic range) for weights or activations.

There is no guarantee that TF32 Tensor Cores are actually used, and there is no way to force the implementation to use them - TensorRT can fall back to FP32 at any time and always falls back if the platform does not support TF32. However you can disable their use by clearing the TF32 builder flag.

C++

```cpp
config->clearFlag(BuilderFlag::kTF32);
```

Python

```python
config.clear_flag(trt.BuilderFlag.TF32)
```

Setting the environment variable `NVIDIA_TF32_OVERRIDE=0` when building an engine disables the use of TF32, despite setting `BuilderFlag::kTF32`. This environment variable, when set to 0, overrides any defaults or programmatic configuration of NVIDIA libraries, so they never accelerate FP32 computations with TF32 Tensor Cores. This is meant to be a debugging tool only, and no code outside NVIDIA libraries should change the behavior based on this environment variable. Any other setting besides 0 is reserved for future use.

**WARNING:** Setting the environment variable `NVIDIA_TF32_OVERRIDE` to a different value when the engine is run can cause unpredictable precision/performance effects. It is best left unset when an engine is run.

**Note:** Unless your application requires the higher dynamic range provided by TF32, FP16 will be a better solution since it almost always yields faster performance.
6.8. I/O Formats

TensorRT optimizes a network using many different data formats. In order to allow efficient passing of data between TensorRT and a client application, these underlying data formats are exposed at network I/O boundaries, that is, for Tensors marked as network input or output, and when passing data to and from plugins. For other tensors, TensorRT picks formats that result in the fastest overall execution, and may insert reformats to improve performance.

You can assemble an optimal data pipeline by profiling the available I/O formats in combination with the formats most efficient for the operations preceding and following TensorRT.

To specify I/O formats, you specify one or more formats in the form of a bitmask. The following example sets the input tensor format to `TensorFormat::kHWC8`. Note that this format only works for `DataType::kHALF`, so the data type must be set accordingly.

**C++**

```c++
auto formats = 1U << TensorFormat::kHWC8;
network->getInput(0)->setAllowedFormats(formats);
network->getInput(0)->setType(DataType::kHALF);
```

**Python**

```python
formats = 1 << int(tensorrt.TensorFormat.HWC8)
network.get_input(0).allowed_formats = formats
network.get_input(0).dtype = tensorrt.DataType.HALF
```

Note that calling `setAllowedFormats()` or `setType()` on a tensor that is not a network input/output, has no effect and is ignored by TensorRT.

It is possible to make TensorRT avoid inserting reformatting at the network boundaries, by setting the builder configuration flag `DIRECT_IO`. This flag is generally counter-productive for two reasons:

- The resulting engine might be slower than if TensorRT had been allowed to insert reformatting. Reformatting may sound like wasted work, but it can allow coupling of the most efficient kernels.
- The build will fail if TensorRT cannot build an engine without introducing such reformatting. The failure may happen only for some target platforms, because of what formats are supported by kernels for those platforms.

The flag exists for the sake of users who want full control over whether reformatting happens at I/O boundaries, such as to build engines that run solely on DLA without falling back to the GPU for reformatting.

[sampleIOFormats](#) illustrates how to specify I/O formats using C++.

The following table shows the supported formats.
Table 1. Supported I/O Formats

</table>

Note that for the vectorized formats, the channel dimension must be zero-padded to the multiple of the vector size. For example, if an input binding has dimensions of [16, 3, 224, 224], kHALF data type, and kHWC8 format, then the actual-required size of the binding buffer would be 16*8*224*224*sizeof(half) bytes, even though the engine->getBindingDimension() API will return tensor dimensions as [16, 3, 224, 224]. The values in the padded part (that is, where \( C = 3, 4, \ldots, 7 \) in this example) must be filled with zeros.

Refer to Data Format Descriptions for how the data are actually laid out in memory for these formats.

6.9. Explicit Versus Implicit Batch

TensorRT supports two modes for specifying a network: explicit batch and implicit batch.

In implicit batch mode, every tensor has an implicit batch dimension and all other dimensions must have constant length. This mode was used by early versions of TensorRT, and is now deprecated but continues to be supported for backwards compatibility.

In explicit batch mode, all dimensions are explicit and can be dynamic, that is their length can change at execution time. Many new features, such as dynamic shapes and loops, are available only in this mode. It is also required by the ONNX parser.

For example, consider a network that processes N images of size HxW with 3 channels, in NCHW format. At runtime, the input tensor has dimensions \([N,3,H,W]\). The two modes differ in how the INetworkDefinition specifies the tensor’s dimensions:
In explicit batch mode, the network specifies \([N,3,H,W]\).

In implicit batch mode, the network specifies only \([3,H,W]\). The batch dimension \(N\) is implicit.

Operations that "talk across a batch" are impossible to express in implicit batch mode because there is no way to specify the batch dimension in the network. Examples of inexpressible operations in implicit batch mode:

- reducing across the batch dimension
- reshaping the batch dimension
- transposing the batch dimension with another dimension

The exception is that a tensor can be broadcast across the entire batch, through the `ITensor::setBroadcastAcrossBatch` method for network inputs, and implicit broadcasting for other tensors.

Explicit batch mode erases the limitations - the batch axis is axis 0. A more accurate term for explicit batch would be "batch oblivious," because in this mode, TensorRT attaches no special semantic meaning to the leading axis, except as required by specific operations. Indeed in explicit batch mode there might not even be a batch dimension (such as a network that handles only a single image) or there might be multiple batch dimensions of unrelated lengths (such as comparison of all possible pairs drawn from two batches).

The choice of explicit versus implicit batch must be specified when creating the `INetworkDefinition`, using a flag. Here is the C++ code for explicit batch mode:

```cpp
IBuilder* builder = ...;
INetworkDefinition* network = builder->createNetworkV2(1U <<
    static_cast<uint32_t>(NetworkDefinitionCreationFlag::kEXPLICIT_BATCH)));
```

For implicit batch, use `createNetwork` or pass a 0 to `createNetworkV2`.

Here is the Python code for explicit batch mode:

```python
builder = trt.Builder(...)  
builder.create_network(1 << int(trt.NetworkDefinitionCreationFlag.EXPLICIT_BATCH))
```

For implicit batch, omit the argument or pass a 0.

## 6.10. Sparsity

NVIDIA Ampere Architecture GPUs support **Structured Sparsity**. To make use of this feature to achieve higher inference performance, the convolution kernel weights and the fully connected weights must meet the following requirements:

For each output channel and for each spatial pixel in the kernel weights, every four input channels must have at least two zeros. In other words, assuming that the kernel weights have the shape \([K, C, R, S]\) and \(C \% 4 == 0\), then the requirement is verified using the following algorithm:

```python
hasSparseWeights = True
for k in range(0, K):
    for r in range(0, R):
        for s in range(0, S):
            for c_packed in range(0, C // 4):
                if numpy.count_nonzero(weights[k, c_packed*4:(c_packed+1)*4, r, s]) > 2 :
```
To enable the sparsity feature, set the `kSPARSE_WEIGHTS` flag in the builder config and make sure that kFP16 or kINT8 modes are enabled. For example:

**C++**
```cpp
config->setFlag(BuilderFlag::kSPARSE_WEIGHTS);
config->setFlag(BuilderFlag::kFP16);
config->setFlag(BuilderFlag::kINT8);
```

**Python**
```python
config.set_flag(trt.BuilderFlag.SPARSE_WEIGHTS)
config.set_flag(trt.BuilderFlag.FP16)
config.set_flag(trt.BuilderFlag.INT8)
```

At the end of the TensorRT logs when the TensorRT engine is built, TensorRT reports which layers contain weights that meet the structured sparsity requirement, and in which layers TensorRT selects tactics that make use of the structured sparsity. In some cases, tactics with structured sparsity can be slower than normal tactics and TensorRT will choose normal tactics in these cases. The following output shows an example of TensorRT logs showing information about sparsity:

```
[03/23/2021-00:14:05] [I] [TRT] (Sparsity) Layers eligible for sparse math: conv1, conv2, conv3
[03/23/2021-00:14:05] [I] [TRT] (Sparsity) TRT inference plan picked sparse implementation for layers: conv2, conv3
```

Forcing kernel weights to have structured sparsity patterns can lead to accuracy loss. To recover lost accuracy with further fine-tuning, refer to the [Automatic SParsity tool in PyTorch](https://pytorch.org/).

To measure inference performance with structured sparsity using `trtexec`, refer to the `trtexec` section.

## 6.11. Empty Tensors

TensorRT supports empty tensors. A tensor is an empty tensor if it has one or more dimensions with length zero. Zero-length dimensions usually get no special treatment. If a rule works for a dimension of length L for an arbitrary positive value of L, it usually works for L=0 too.

For example, when concatenating two tensors with dimensions [x,y,z] and [x,y,w] along the last axis, the result has dimensions [x,y,z+w], regardless of whether x, y, z, or w is zero.

Implicit broadcast rules remain unchanged since only unit-length dimensions are special for broadcast. For example, given two tensors with dimensions [1,y,z] and [x,1,z], their sum computed by `IElementWiseLayer` has dimensions [x,y,z], regardless of whether x, y, or z is zero.

If an engine binding is an empty tensor, it still needs a non-null memory address, and different tensors should have different addresses. This is consistent with the C++ rule that every object has a unique address, for example, `new float[0]` returns a non-null pointer. If using a memory allocator that might return a null pointer for zero bytes, ask for at least one byte instead.

Refer to the [NVIDIA TensorRT Operator’s Reference](https://developer.nvidia.com/tensorrt) for any per-layer special handling of empty tensors.
6.12. Reusing Input Buffers

TensorRT allows specifying a CUDA event to be signaled once the input buffers are free to be reused. This allows the application to immediately start refilling the input buffer region for the next inference in parallel with finishing the current inference. For example:

**C++**
```cpp
context->setInputConsumedEvent(&inputReady);
```

**Python**
```python
context.set_input_consumed_event(inputReady)
```

6.13. Engine Inspector

TensorRT provides the `IEngineInspector` API to inspect the information inside a TensorRT engine. Call the `createEngineInspector()` from a deserialized engine to create an engine inspector, and then call `getLayerInformation()` or `getEngineInformation()` inspector APIs to get the information of a specific layer in the engine or the entire engine, respectively. You can print out the information of the first layer of the given engine, as well as the overall information of the engine, as follows:

**C++**
```cpp
auto inspector = std::unique_ptr<IEngineInspector>(engine->createEngineInspector());
inspector->setExecutionContext(context); // OPTIONAL
std::cout << inspector->getLayerInformation(0, LayerInformationFormat::kJSON); // Print the information of the first layer in the engine.
std::cout << inspector->getEngineInformation(LayerInformationFormat::kJSON); // Print the information of the entire engine.
```

**Python**
```python
inspector = engine.create_engine_inspector();
inspector.execution_context = context; # OPTIONAL
print(inspector.get_layer_information(0, LayerInformationFormat.JSON); # Print the information of the first layer in the engine.
print(inspector.get_engine_information(LayerInformationFormat.JSON); # Print the information of the entire engine.
```

Note that the level of detail in the engine/layer information depends on the `ProfilingVerbosity` builder config setting when the engine is built. By default, `ProfilingVerbosity` is set to `kLAYER_NAMES_ONLY`, so only the layer names will be printed. If `ProfilingVerbosity` is set to `kNONE`, then no information will be printed; if it is set to `kDETAILED`, then detailed information will be printed.

Below are some examples of layer information printed by `getLayerInformation()` API depending on the `ProfilingVerbosity` setting:

**kLAYER_NAMES_ONLY**
```
"node_of_gpu_0/res4_0_branch2a_1 + node_of_gpu_0/res4_0_branch2a_bn_1 + node_of_gpu_0/res4_0_branch2a_bn_2"
```

**kDETAILED**
```
{
  "Name": "node_of_gpu_0/res4_0_branch2a_1 + node_of_gpu_0/res4_0_branch2a_bn_1 + node_of_gpu_0/res4_0_branch2a_bn_2",
  "LayerType": "CaskConvolution",
  "Inputs": [  
```
"Name": "gpu_0/res3_3_branch2c_bn_3",
"Dimensions": [16,512,28,28],
"Format/Datatype": "Thirty-two wide channel vectorized row major Int8 format."
},
"Outputs": [
{
"Name": "gpu_0/res4_0_branch2a_bn_2",
"Dimensions": [16,256,28,28],
"Format/Datatype": "Thirty-two wide channel vectorized row major Int8 format."
}
],
"ParameterType": "Convolution",
"Kernel": [1,1],
"PaddingMode": "kEXPLICIT_ROUND_DOWN",
"PrePadding": [0,0],
"PostPadding": [0,0],
"Stride": [1,1],
"Dilation": [1,1],
"OutMaps": 256,
"Groups": 1,
"Weights": {"Type": "Int8", "Count": 131072},
"Bias": {"Type": "Float", "Count": 256},
"AllowSparse": 0,
"Activation": "RELU",
"HasBias": 1,
"HasReLU": 1,
"TacticName": "sm80_xmma_fprop_implicit_gemm_interleaved_i8i8_i8i8_i8i32_f32_nchw_vect_c_32kcrs_vect_c_32_nchw_vect_c_32_tilesize256x128x64_stage4_warpsize4x2x1_g1_tensor16x8x32_simple_t1r1s1_epifadd",
"TacticValue": "0x11bde0e1d9f2f35d"
}

In addition, when the engine is built with dynamic shapes, the dynamic dimensions in the engine information will be shown as -1 and the tensor format information will not be shown because these fields depend on the actual shape at inference phase. To get the engine information for a specific inference shape, create an IExecutionContext, set all the input dimensions to the desired shapes, and then call inspector->setExecutionContext(context). After the context is set, the inspector will print the engine information for the specific shape set in the context.

The trtexec tool provides the --profilingVerbosity, --dumpLayerInfo, and --exportLayerInfo flags that can be used to get the engine information of a given engine. Refer to the trtexec section for more details.

Currently, only binding information and layer information, including the dimensions of the intermediate tensors, precisions, formats, tactic indices, layer types, and layer parameters, are included in the engine information. More information may be added into the engine inspector output as new keys in the output JSON object in future TensorRT versions. More specifications about the keys and the fields in the inspector output will also be provided.

In addition, some subgraphs are handled by a next-generation graph optimizer that is not yet integrated with the engine inspector. Therefore, the layer information within these layers is not currently shown. This will be improved in a future TensorRT version.

6.14. Preview Features

The preview feature API is an extension of IBuilderConfig to allow the gradual introduction of new features to TensorRT. Selected new features are exposed under this API, allowing you to opt in or opt out. A preview feature remains in preview status...
for one or two TensorRT release cycles, and is then either integrated as a mainstream feature, or dropped. When a preview feature is fully integrated into TensorRT, it is no longer controllable through the preview API.

Preview features are defined using a 32-bit `PreviewFeature` enumeration. Feature identifiers are a concatenation of the feature name and the TensorRT version. `<FEATURE_NAME>_XXYY`

Where `XX` and `YY` are the TensorRT major and minor versions, respectively, of the TensorRT release which first introduced the feature. The major and minor versions are specified using two digits with leading-zero padding when necessary.

If the semantics of a preview feature change from one TensorRT release to another, the older preview feature is deprecated and the revised feature is assigned a new enumeration value and name.

Deprecated preview features are marked in accordance with the [deprecation policy](#).

For more information about the C++ API, refer to `nvinfer1::PreviewFeature`, `IBuilderConfig::setPreviewFeature`, and `IBuilderConfig::getPreviewFeature`.

The Python API has similar semantics using the `PreviewFeature` enum and `set_preview_feature`, and `get_preview_feature` functions.
Chapter 7. Working with INT8

7.1. Introduction to Quantization

TensorRT supports the use of 8-bit integers to represent quantized floating point values. The quantization scheme is symmetric uniform quantization - quantized values are represented in signed INT8, and the transformation from quantized to unquantized values is simply a multiplication. In the reverse direction, quantization uses the reciprocal scale, followed by rounding and clamping.

The quantization scheme includes quantization of activations as well as weights.

The quantization scheme for activations depends on the chosen calibration algorithm to find a scale \( s \) which best balances rounding error and precision error for specific data. Different calibration schemes supported by TensorRT can be found Post-Training Quantization Using Calibration.

The quantization scheme for weights is as follows:

\[
\text{quantize}(x, s) = \text{roundWithTiesToEven}(\text{clip}(x, \frac{X}{s}, -128, 127))
\]

- \( x_q \) is quantized value in range \([-128,127]\).
- \( x \) is a floating point value of the activation.
- \text{roundWithTiesToEven} is described here.

\[
x = \text{dequantize}(x_q, s) = x_q \times s
\]

For DLA on Orin, the quantization scheme is updated to use a different rounding mode:

\[
x_q = \text{quantize}(x, s) = \text{roundWithTiesToNearestEven}(\text{clip}(x, \frac{X}{s}, -128, 127))
\]

To enable the use of any quantized operations, the INT8 flag must be set in the builder configuration.
7.1.1. Quantization Workflows

There are two workflows for creating quantized networks:

Post-training quantization (PTQ) derives scale factors after the network has been trained. TensorRT provides a workflow for PTQ, called calibration, where it measures the distribution of activations within each activation tensor as the network executes on representative input data, then uses that distribution to estimate a scale value for the tensor.

Quantization-aware training (QAT) computes scale factors during training. This allows the training process to compensate for the effects of the quantization and dequantization operations.

TensorRT’s Quantization Toolkit is a PyTorch library that helps produce QAT models that can be optimized by TensorRT. You can also use the toolkit’s PTQ recipe to perform PTQ in PyTorch and export to ONNX.

7.1.2. Explicit Versus Implicit Quantization

Quantized networks can be represented in two ways:

In implicitly quantized networks, each quantized tensor has an associated scale. When reading and writing the tensor, the scale is used to implicitly quantize and dequantize values.

When processing implicitly quantized networks, TensorRT treats the model as a floating-point model when applying the graph optimizations, and uses INT8 opportunistically to optimize layer execution time. If a layer runs faster in INT8, then it executes in INT8. Otherwise, FP32 or FP16 is used. In this mode, TensorRT is optimizing for performance only, and you have little control over where INT8 is used - even if you explicitly set the precision of a layer at the API level, TensorRT may fuse that layer with another during graph optimization, and lose the information that it must execute in INT8. TensorRT’s PTQ capability generates an implicitly quantized network.

In explicitly quantized networks, the scaling operations to transform between the quantized and unquantized values are represented explicitly by IQuantizeLayer (C++, Python) and IDequantizeLayer (C++, Python) nodes in the graph - these will henceforth be referred to as Q/DQ nodes. By contrast with implicit quantization, the explicit form specifies exactly where conversion to and from INT8 is performed, and the optimizer will perform only precision conversions that are dictated by the semantics of the model, even if:

- adding extra conversions could increase layer precision (for example, choosing an FP16 kernel implementation over an INT8 implementation)
- adding extra conversions results in an engine that executes faster (for example, choosing an INT8 kernel implementation to execute a layer specified as having float precision or vice versa)

ONNX uses an explicitly quantized representation - when a model in PyTorch or TensorFlow is exported to ONNX, each fake-quantization operation in the framework’s graph is exported as Q followed by DQ. Since TensorRT preserves the semantics of these
layers, you can expect task accuracy very close to that seen in the framework. While optimizations preserve the placement of quantization and dequantization, they may change the order of floating-point operations in the model, so results will not be bitwise identical.

Note that by contrast with TensorRT’s PTQ, performing either QAT or PTQ in a framework and then exporting to ONNX will result in an explicitly quantized model.

For more background on quantization, refer to the [Integer Quantization for Deep Learning Inference: Principles and Empirical Evaluation](https://example.com) paper.

**7.1.3. Per-Tensor and Per-Channel Quantization**

There are two common quantization scale granularities:

- **Per-tensor quantization**: in which a single scale value (scalar) is used to scale the entire tensor.

- **Per-channel quantization**: in which a scale tensor is broadcast along the given axis - for convolutional neural networks, this is typically the channel axis.

With explicit quantization, weights can be quantized using per-tensor quantization or they can be quantized using per-channel quantization. In either case, the scale precision is FP32. Activation can only be quantized using per-tensor quantization.
When using per-channel quantization, the axis of quantization must be the output-channel axis. For example, when the weights of 2D convolution are described using $KCRS$ notation, $K$ is the output-channel axis, and the weights quantization can be described as:

```
For each $k$ in $K$:
  For each $c$ in $C$:
    For each $r$ in $R$:
      For each $s$ in $S$:
        output[$k,c,r,s$] := clamp(round(input[$k,c,r,s$] / scale[$k$]))
```

One exception is deconvolution (also known as transposed convolution), which must be quantized on the input-channel axis.

The scale is a vector of coefficients and must have the same size as the quantization axis. The quantization scale must consist of all positive float coefficients. The rounding method is rounding-to-nearest ties-to-even and clamping is in the range $[-128, 127]$.

Dequantization is performed similarly except for the pointwise operation that is defined as:

```
output[$k,c,r,s$] := input[$k,c,r,s$] * scale[$k$]
```

TensorRT supports only per-tensor quantization for activation tensors, but supports per-channel weight quantization for convolution, deconvolution, fully connected layers, and MatMul where the second input is constant and both input matrices are 2D.

### 7.2. Setting Dynamic Range

TensorRT provides APIs to set dynamic range (the range that must be represented by the quantized tensor) directly, to support implicit quantization where these values have been calculated outside TensorRT.

The API allows setting the dynamic range for a tensor using minimum and maximum values. Since TensorRT currently supports only symmetric range, the scale is calculated using $\max(\text{abs}(\text{min\_float}), \text{abs}(\text{max\_float}))$. Note that when $\text{abs}(\text{min\_float}) \neq \text{abs}(\text{max\_float})$, TensorRT uses a larger dynamic-range than configured, which may increase the rounding error.

Dynamic range is needed for all floating-point inputs and outputs of an operation that will execute in INT8.

You can set the dynamic range for a tensor as follows:

**C++**

```
tensor->setDynamicRange(min_float, max_float);
```

**Python**

```
tensor.dynamic_range = (min_float, max_float)
```

[sampleINT8API](https://example.com) illustrates the use of these APIs in C++.
7.3. Post-Training Quantization Using Calibration

In post-training quantization, TensorRT computes a scale value for each tensor in the network. This process, called calibration, requires you to supply representative input data on which TensorRT runs the network to collect statistics for each activation tensor.

The amount of input data required is application-dependent, but experiments indicate that about 500 images are sufficient for calibrating ImageNet classification networks.

Given the statistics for an activation tensor, deciding on the best scale value is not an exact science - it requires balancing two sources of error in the quantized representation: discretization error (which increases as the range represented by each quantized value becomes larger) and truncation error (where values are clamped to the limits of the representable range.) Thus, TensorRT provides multiple different calibrators that calculate the scale in different ways. Older calibrators also performed layer fusion for GPU to optimize away unneeded Tensors before performing calibration. This can be problematic when using DLA, where fusion patterns may be different, and can be overridden using the kCALIBRATE_BEFORE_FUSION quantization flag.

Calibration batch size can also affect the truncation error for IInt8EntropyCalibrator2 and IInt8EntropyCalibrator. For example, calibrating using multiple small batches of calibration data may result in reduced histogram resolution and poor scale value. For each calibration step, TensorRT updates the histogram distribution for each activation tensor. If it encounters a value in the activation tensor, larger than the current histogram max, the histogram range is increased by a power of two to accommodate the new maximum value. This approach works well unless histogram reallocation occurs in the last calibration step, resulting in a final histogram with half the bins empty. Such a histogram can produce poor calibration scales. This also makes calibration susceptible to the order of calibration batches, that is, a different order of calibration batches can result in the histogram size being increased at different points, producing slightly different calibration scales. To avoid this issue, calibrate with as large a single batch as possible, and ensure that calibration batches are well randomized and have similar distribution.

**IInt8EntropyCalibrator2**
Entropy calibration chooses the tensor’s scale factor to optimize the quantized tensor’s information-theoretic content, and usually suppresses outliers in the distribution. This is the current and recommended entropy calibrator and is required for DLA. Calibration happens before Layer fusion by default. Calibration batch size may impact the final result. It is recommended for CNN-based networks.

**IInt8MinMaxCalibrator**
This calibrator uses the entire range of the activation distribution to determine the scale factor. It seems to work better for NLP tasks. Calibration happens before Layer fusion by default. This is recommended for networks such as NVIDIA BERT (an optimized version of Google’s official implementation).
IInt8EntropyCalibrator
This is the original entropy calibrator. It is less complicated to use than the LegacyCalibrator and typically produces better results. Calibration batch size may impact the final result. Calibration happens after Layer fusion by default.

IInt8LegacyCalibrator
This calibrator is for compatibility with TensorRT 2.0 EA. This calibrator requires user parameterization and is provided as a fallback option if the other calibrators yield poor results. Calibration happens after Layer fusion by default. You can customize this calibrator to implement percentile max, for example, 99.99% percentile max is observed to have best accuracy for NVIDIA BERT and NeMo ASR model QuartzNet.

When building an INT8 engine, the builder performs the following steps:

1. Build a 32-bit engine, run it on the calibration set, and record a histogram for each tensor of the distribution of activation values.
2. Build from the histograms a calibration table providing a scale value for each tensor.
3. Build the INT8 engine from the calibration table and the network definition.

Calibration can be slow; therefore the output of step 2 (the calibration table) can be cached and reused. This is useful when building the same network multiple times on a given platform and is supported by all calibrators.

Before running calibration, TensorRT queries the calibrator implementation to see if it has access to a cached table. If so, it proceeds directly to step 3. Cached data is passed as a pointer and length. A sample calibration table can be found here.

The calibration cache data is portable across different devices as long as the calibration happens before layer fusion. Specifically, the calibration cache is portable when using the IInt8EntropyCalibrator2 or IInt8MinMaxCalibrator calibrators, or when QuantizationFlag::kCALIBRATE_BEFORE_FUSION is set. This can simplify the workflow, for example by building the calibration table on a machine with a discrete GPU and then reusing it on an embedded platform. Fusions are not guaranteed to be the same across platforms or devices, so calibrating after layer fusion may not result in a portable calibration cache. The calibration cache is in general not portable across TensorRT releases.

As well as quantizing activations, TensorRT must also quantize weights. It uses symmetric quantization with a quantization scale calculated using the maximum absolute values found in the weight tensor. For convolution, deconvolution, and fully connected weights, scales are per-channel.

Note: When the builder is configured to use INT8 I/O, TensorRT still expects calibration data to be in FP32. You can create FP32 calibration data by casting INT8 I/O calibration data to FP32 precision. Also ensure that FP32 cast calibration data is in the range [-128.0F, 127.0F] and so can be converted to INT8 data without any precision loss.

INT8 calibration can be used along with the dynamic range APIs. Setting the dynamic range manually overrides the dynamic range generated from INT8 calibration.

Note: Calibration is deterministic - that is, if you provide TensorRT with the same input to calibration in the same order on the same device, the scales generated will be the same.
across different runs. The data in the calibration cache will be bitwise identical when generated using the same device with the same batch size when provided with identical calibration inputs. The exact data in the calibration cache is not guaranteed to be bitwise identical when generated using different devices, different batch sizes, or using different calibration inputs.

7.3.1. INT8 Calibration Using C++
To provide calibration data to TensorRT, implement the `IInt8Calibrator` interface. The builder invokes the calibrator as follows:

- First, it queries the interface for the batch size and calls `getBatchSize()` to determine the size of the input batch to expect.
- Then, it repeatedly calls `getBatch()` to obtain batches of input. Batches must be exactly the batch size by `getBatchSize()`. When there are no more batches, `getBatch()` must return `false`.

After you have implemented the calibrator, you can configure the builder to use it:
```
config->setInt8Calibrator(calibrator.get());
```
To cache the calibration table, implement the `writeCalibrationCache()` and `readCalibrationCache()` methods.

7.3.2. Calibration Using Python
The following steps illustrate how to create an INT8 calibrator object using the Python API.

1. Import TensorRT:
   ```python
   import tensorrt as trt
   ```

2. Similar to test/validation datasets, use a set of input files as a calibration dataset. Make sure that the calibration files are representative of the overall inference data files. For TensorRT to use the calibration files, you must create a `batchstream` object. A `batchstream` object is used to configure the calibrator.
   ```python
   NUM_IMAGES_PER_BATCH = 5
   batchstream = ImageBatchStream(NUM_IMAGES_PER_BATCH, calibration_files)
   ```

3. Create an `Int8_calibrator` object with input nodes names and batch stream:
   ```python
   Int8_calibrator = EntropyCalibrator(\["input_node_name"\], batchstream)
   ```

4. Set INT8 mode and INT8 calibrator:
   ```python
   config.set_flag(trt.BuilderFlag.INT8)
   config.int8_calibrator = Int8_calibrator
   ```

7.3.3. Quantization Noise Reduction
For networks with implicit quantization, TensorRT attempts to reduce quantization noise in the output by forcing some layers near the network outputs to run in FP32, even if INT8 implementations are available.

The heuristic attempts to ensure that INT8 quantization is smoothed out by summation of multiple quantized values. Layers considered to be "smoothing layers" are convolution,
deconvolution, a fully connected layer, or matrix multiplication before reaching the network output. For example, if a network consists of a series of (convolution + activation + shuffle) subgraphs and the network output has type FP32, the last convolution will output FP32 precision, even if INT8 is allowed and faster.

The heuristic does not apply in the following scenarios:

- The network output has type INT8.
- An operation on the path (inclusively) from the last smoothing layer to the output is constrained by ILayer::setOutputType or ILayer::setPrecision to output INT8.
- There is no smoothing layer with a path to the output, or said that path has an intervening plugin layer.
- The network uses explicit quantization.

7.4. Explicit Quantization

When TensorRT detects the presence of Q/DQ layers in a network, it builds an engine using explicit-precision processing logic.

A Q/DQ network must be built with the INT8-precision builder flag enabled:

```c++
config->setFlag(BuilderFlag::kINT8);
```

In explicit-quantization, network changes of representation to and from INT8 are explicit, therefore, INT8 must not be used as a type constraint.

7.4.1. Quantized Weights

Weights of Q/DQ models must be specified using FP32 data type. The weights are quantized by TensorRT using the scale of the IQuantizeLayer that operates on the weights. The quantized weights are stored in the Engine file. Prequantized weights can also be used but must be specified using FP32 data-type. The scale of the Q node must be set to 1.0F, but the DQ node must be the real scale value.

7.4.2. ONNX Support

When a model trained in PyTorch or TensorFlow using Quantization Aware Training (QAT) is exported to ONNX, each fake-quantization operation in the framework's graph is exported as a pair of QuantizeLinear and DequantizeLinear ONNX operators.

When TensorRT imports ONNX models, the ONNX QuantizeLinear operator is imported as an IQuantizeLayer instance, and the ONNX DequantizeLinear operator is imported as an IDequantizeLayer instance. ONNX using opset 10 introduced support for QuantizeLinear/DequantizeLinear, and a quantization-axis attribute was added in opset 13 (required for per-channel quantization). PyTorch 1.8 introduced support for exporting PyTorch models to ONNX using opset 13.

**WARNING:** The ONNX GEMM operator is an example that can be quantized per channel. PyTorch torch.nn.Linear layers are exported as an ONNX GEMM operator with `(K, C)` weights layout and with the transB GEMM attribute enabled (this transposes the
PyTorch weights are therefore transposed by TensorRT. The weights are quantized by TensorRT before they are transposed, so GEMM layers originating from ONNX QAT models that were exported from PyTorch use dimension 0 for per-channel quantization (axis $K = 0$); while models originating from TensorFlow use dimension 1 (axis $K = 1$).

TensorRT does not support prequantized ONNX models that use INT8 tensors or quantized operators. Specifically, the following ONNX quantized operators are not supported and generates an import error if they are encountered when TensorRT imports the ONNX model:

- QLinearConv/QLinearMatmul
- ConvInteger/MatmulInteger

### 7.4.3. TensorRT Processing of Q/DQ Networks

When TensorRT optimizes a network in Q/DQ-mode, the optimization process is limited to optimizations that do not change the arithmetic correctness of the network. Bit-level accuracy is rarely possible since the order of floating-point operations can produce different results (for example, rewriting $a \ast s + b \ast s$ as $(a + b) \ast s$ is a valid optimization). Allowing these differences is fundamental to backend optimization in general, and this also applies to converting a graph with Q/DQ layers to use INT8 computation.

Q/DQ layers control the compute and data precision of a network. An IQuantizeLayer instance converts an FP32 tensor to an INT8 tensor by employing quantization, and an IDequantizeLayer instance converts an INT8 tensor to an FP32 tensor by means of dequantization. TensorRT expects a Q/DQ layer pair on each of the inputs of quantizable-layers. Quantizable-layers are deep-learning layers that can be converted to quantized layers by fusing with IQuantizeLayer and IDequantizeLayer instances. When TensorRT performs these fusions, it replaces the quantizable-layers with quantized layers that actually operate on INT8 data using INT8 compute operations.

For the diagrams used in this chapter, green designates INT8 precision and blue designates floating-point precision. Arrows represent network activation tensors and squares represent network layers.
Figure 1. A quantizable `AveragePool` layer (in blue) is fused with a DQ layer and a Q layer. All three layers are replaced by a quantized `AveragePool` layer (in green).

During network optimization, TensorRT moves Q/DQ layers in a process called Q/DQ propagation. The goal in propagation is to maximize the proportion of the graph that can be processed at low precision. Thus, TensorRT propagates Q nodes backwards (so that quantization happens as early as possible) and DQ nodes forward (so that dequantization happens as late as possible). Q-layers can swap places with layers that commute-with-Quantization and DQ-layers can swap places with layers that commute-with-Dequantization.

A layer $\text{Op}$ commutes with quantization if $Q\left(\text{Op}\left(x\right)\right) = \text{Op}\left(Q\left(x\right)\right)$

Similarly, a layer $\text{Op}$ commutes with dequantization if $\text{Op}\left(DQ\left(x\right)\right) = DQ\left(\text{Op}\left(x\right)\right)$

The following diagram illustrates DQ forward-propagation and Q backward-propagation. These are legal rewrites of the model because Max Pooling has an INT8 implementation and because Max Pooling commutes with DQ and with Q.

Figure 2. An illustration depicting a DQ forward-propagation and Q backward-propagation.

Note:
To understand Max Pooling commutation, let us look at the output of the maximum-pooling operation applied to some arbitrary input. Max Pooling is applied to groups of
input coefficients and outputs the coefficient with the maximum value. For group \(i\) composed of coefficients: \(\{x_0, \ldots, x_m\}\):

\[
\text{output}_i := \max\{x_0, x_1, \ldots, x_m\} = \max\{\max\{\max\{x_0, x_1\}, x_2\}, \ldots, x_m\}\]

It is therefore enough to look at two arbitrary coefficients without loss of generality (WLOG):

\[
x_j = \max\{x_j, x_k\} \quad \text{for} \quad x_j > = x_k
\]

For quantization function \(Q(a, \text{scale}, x_{\text{max}}, x_{\text{min}}) := \text{truncate}\left(\text{round}\left(a / \text{scale}\right)\right), x_{\text{max}}, x_{\text{min}}\) with \(\text{scale} > 0\), note that (without providing proof, and using simplified notation):

\[
Q(x_j, \text{scale}) > = Q(x_k, \text{scale}) \quad \text{for} \quad x_j > = x_k
\]

Therefore:

\[
\max\{Q(x_j, \text{scale}), Q(x_k, \text{scale})\} = Q(x_j, \text{scale}) \quad \text{for} \quad x_j > = x_k
\]

However, by definition:

\[
Q(\max\{x_j, x_k\}, \text{scale}) = Q(x_j, \text{scale}) \quad \text{for} \quad x_j > = x_k
\]

Function max commutes-with-quantization and so does Max Pooling.

Similarly for dequantization, function \(DQ(a, \text{scale}) := a * \text{scale} \quad \text{with} \quad \text{scale} > 0\) we can show that:

\[
\max\{DQ(x_j, \text{scale}), DQ(x_k, \text{scale})\} = DQ(x_j, \text{scale}) = DQ(\max\{x_j, x_k\}, \text{scale}) \quad \text{for} \quad x_j > = x_k
\]

There is a distinction between how quantizable-layers and commuting-layers are processed. Both types of layers can compute in INT8, but quantizable-layers also fuse with DQ input layers and a Q output layer. For example, an \texttt{AveragePooling} layer (quantizable) does not commute with either Q or DQ, so it is quantized using Q/DQ fusion as illustrated in the first diagram. This is in contrast to how Max Pooling (commuting) is quantized.

### 7.4.4. Q/DQ Layer-Placement Recommendations

The placement of Q/DQ layers in a network affects performance and accuracy. Aggressive quantization can lead to degradation in model accuracy because of the error introduced by quantization. But quantization also enables latency reductions. Listed here are some recommendations for placing Q/DQ layers in your network.

**Quantize all inputs of weighted-operations** (Convolution, Transposed Convolution, and GEMM). Quantization of the weights and activations reduces bandwidth requirements and also enables INT8 computation to accelerate bandwidth-limited and compute-limited layers.

SM 7.5 and earlier devices may not have INT8 implementations for all layers. In this case, you will encounter a \texttt{could not find any implementation} error while building your engine. To resolve this, remove the Q/DQ nodes which quantize the failing layers.
Figure 3. Two examples of how TensorRT fuses convolutional layers. On the left, only the inputs are quantized. On the right, both inputs and output are quantized.

By default, do not quantize the outputs of weighted-operations. It is sometimes useful to preserve the higher-precision dequantized output. For example, if the linear operation is followed by an activation function (SiLU, in the following diagram) that requires higher precision input to produce acceptable accuracy.

Figure 4. Example of a linear operation followed by an activation function.

Do not simulate batch-normalization and ReLU fusions in the training framework because TensorRT optimizations guarantee to preserve the arithmetic semantics of these operations.
Figure 5. Batch normalization is fused with convolution and ReLU while keeping the same execution order as defined in the pre-fusion network. There is no need to simulate BN-folding in the training network.

**Quantize the residual input in skip-connections.** TensorRT can fuse element-wise addition following weighted layers, which are useful for models with skip connections like ResNet and EfficientNet. The precision of the first input to the element-wise addition layer determines the precision of the output of the fusion.

For example, in the following diagram, the precision of \( x_f \) is floating point, so the output of the fused convolution is limited to floating-point, and the trailing Q-layer cannot be fused with the convolution.
Figure 6. The precision of $x_f^1$ is floating point, so the output of the fused convolution is limited to floating-point, and the trailing Q-layer cannot be fused with the convolution.

Figure 7. When $x_f^1$ is quantized to INT8, the output of the fused convolution is also INT8, and the trailing Q-layer is fused with the convolution.
For extra performance, **try quantizing layers that do not commute with Q/DQ.** Currently, non-weighted layers that have INT8 inputs also require INT8 outputs, so quantize both inputs and outputs.

**Figure 8.** An example of quantizing a quantizable operation. An element-wise addition is fused with the input DQs and the output Q.

Performance can decrease if TensorRT cannot fuse the operations with the surrounding Q/DQ layers, so **be conservative when adding Q/DQ nodes and experiment with accuracy and TensorRT performance** in mind.

The following figure is an example of suboptimal fusions (the highlighted light green background rectangles) that can result from extra Q/DQ operations. Contrast the following figure with **Figure 7**, which shows a more performant configuration. The convolution is fused separately from the element-wise addition because each of them is surrounded by Q/DQ pairs. The fusion of the element-wise addition is shown in **Figure 8**.
Figure 9. An example of suboptimal quantization fusions: contrast the suboptimal fusion in A and the optimal fusion in B. The extra pair of Q/DQ operations (highlighted with a glowing-green border) forces the separation of the convolution from the element-wise addition.

Use per-tensor quantization for activations; and per-channel quantization for weights. This configuration has been demonstrated empirically to lead to the best quantization accuracy.

You can further optimize engine latency by enabling FP16. TensorRT attempts to use FP16 instead of FP32 whenever possible (this is not currently supported for all layer types).

7.4.5. Q/DQ Limitations

A few of the Q/DQ graph-rewrite optimizations that TensorRT performs compare the values of quantization scales between two or more Q/DQ layers and only perform the graph-rewrite if the compared quantization scales are equal. When a refittable TensorRT engine is refitted, the scales of Q/DQ nodes can be assigned new values. During the refitting operation of Q/DQ engines, TensorRT checks if Q/DQ layers that participated in scale-dependent optimizations are assigned new values that break the rewrite optimizations and throws an exception if true.
Figure 10. An example showing scales of Q1 and Q2 are compared for equality, and if equal, they are allowed to propagate backward. If the engine is refitted with new values for Q1 and Q2 such that $Q_1 \neq Q_2$, then an exception aborts the refitting process.

7.4.6. Q/DQ Interaction with Plugins

Plugins extend the capabilities of TensorRT by allowing the replacement of a group of layers with a custom and proprietary implementation. You can decide what functionality to include in the plugin and what to leave for TensorRT to handle.

The same follows for a TensorRT network with Q/DQ layers: when a plugin consumes quantized INT8 inputs and generates quantized INT8 outputs, the input DQ and output Q nodes must be included as part of the plugin and removed from the network.

Consider a simple case of a sequential graph consisting of a single INT8 plugin (aptly named MyInt8Plugin) sandwiched between two convolution layers (ignoring weights quantization):

```
Input > Q -> DQ > Conv > Q -> DQ_i > MyInt8Plugin > Q_o -> DQ > Conv > Output
```

The > arrows indicate activation tensors with FP32 precision and the \(\rightarrow\) arrows indicate INT8 precision.

When TensorRT optimizes this graph, it fuses the layers to the following graph (square brackets indicate TensorRT fusions):

```
Input > Q -> [DQ \rightarrow Conv \rightarrow Q] \rightarrow DQ_i > MyInt8Plugin > Q_o \rightarrow [DQ \rightarrow Conv] \rightarrow Output
```

In the graph above, the plugin consumes and generates FP32 inputs and outputs. Since the plugin MyInt8Plugin uses INT8 precision, the next step is to manually “fuse” DQ_i and Q_o with MyInt8Plugin, so TensorRT will see a network like this:

```
Input > Q -> DQ > Conv > Q -> MyInt8Plugin -> DQ > Conv > Output
```

Which it will fuse to:
When "manually fusing" $\textit{DQ}_i$, you take the input quantization scale and give it to your plugin, so it will know how to dequantize (if needed) the input. The same follows for using the scale from $\textit{Q}_o$ in order to quantize your plugin's output.

7.4.7. QAT Networks Using TensorFlow

We provide an open-source TensorFlow-Quantization Toolkit to perform QAT in TensorFlow 2 Keras models following NVIDIA's QAT recipe. This leads to optimal model acceleration with TensorRT on NVIDIA GPUs and hardware accelerators. More details can be found in the NVIDIA TensorFlow-Quantization Toolkit User Guide.

TensorFlow 1 does not support per-channel quantization (PCQ). PCQ is recommended for weights in order to preserve the accuracy of the model.

7.4.8. QAT Networks Using PyTorch

PyTorch 1.8.0 and forward support ONNX QuantizeLinear/DequantizeLinear support per channel scales. You can use pytorch-quantization to do INT8 calibration, run quantization aware fine-tuning, generate ONNX and finally use TensorRT to run inference on this ONNX model. More detail can be found in NVIDIA PyTorch-Quantization Toolkit User Guide.

7.5. INT8 Rounding Modes

Chapter 8. Working with Dynamic Shapes

*Dynamic Shapes* is the ability to defer specifying some or all tensor dimensions until runtime. Dynamic shapes can be used through both the C++ and Python interfaces.

The following sections provide greater detail; however, here is an overview of the steps for building an engine with dynamic shapes:

1. The network definition must not have an implicit batch dimension.
   - **C++**
     ```cpp
     IBuilder::createNetworkV2(1U <<
     static_cast<int>(NetworkDefinitionCreationFlag::kEXPLICIT_BATCH))
     ```
   - **Python**
     ```python
     create_network(1 <<
     int(tensorrt.NetworkDefinitionCreationFlag.EXPLICIT_BATCH))
     ```
   These calls request that the network not have an implicit batch dimension.

2. Specify each runtime dimension of an input tensor by using −1 as a placeholder for the dimension.

3. Specify one or more *optimization profiles* at build time that specify the permitted range of dimensions for inputs with runtime dimensions, and the dimensions for which the auto-tuner will optimize. For more information, refer to [Optimization Profiles](#).

4. To use the engine:
   a. Create an execution context from the engine, the same as without dynamic shapes.
   b. Specify one of the optimization profiles from step 3 that covers the input dimensions.
   c. Specify the input dimensions for the execution context. After setting input dimensions, you can get the output dimensions that TensorRT computes for the given input dimensions.
   d. Enqueue work.

To change the runtime dimensions, repeat steps 4b and 4c, which do not have to be repeated until the input dimensions change.
When the preview features (PreviewFeature::kFASTER_DYNAMIC_SHAPES_0805) is enabled, it can potentially, for dynamically shaped networks:

- reduce the engine build time,
- reduce runtime, and
- decrease device memory usage and engine size.

Models most likely to benefit from enabling kFASTER_DYNAMIC_SHAPES_0805 are transformer-based models and models containing dynamic control flows.

## 8.1. Specifying Runtime Dimensions

When building a network, use `-1` to denote a runtime dimension for an input tensor. For example, to create a 3D input tensor named `foo` where the last two dimensions are specified at runtime, and the first dimension is fixed at build time, issue the following.

### C++

```cpp
networkDefinition.addInput("foo", DataType::kFLOAT, Dims3(3, -1, -1))
```

### Python

```python
network_definition.add_input("foo", trt.float32, (3, -1, -1))
```

At run time, you must set the input dimensions after choosing an optimization profile (refer to Optimization Profiles). Let the input have dimensions `[3, 150, 250]`. After setting an optimization profile for the previous example, you would call:

### C++

```cpp
context.setInputShape("foo", Dims{3, {3, 150, 250}})
```

### Python

```python
context.set_input_shape("foo", (3, 150, 250))
```

At runtime, asking the engine for binding dimensions returns the same dimensions used to build the network, meaning, you get a `-1` for each runtime dimension. For example:

### C++

```cpp
engine.getTensorShape("foo") returns a Dims with dimensions {3, -1, -1}.
```

### Python

```python
engine.get_tensor_shape("foo") returns (3, -1, -1).
```

To get the actual dimensions, which are specific to each execution context, query the execution context:

### C++

```cpp
context.getTensorShape("foo") returns a Dims with dimensions {3, 150, 250}.
```

### Python

```python
context.get_tensor_shape(0) returns (3, 150, 250).
```

---

**Note:** The return value of `setInputShape` for an input only indicates consistency with respect to the optimization profile set for that input. After all input binding dimensions are specified, you can check whether the entire network is consistent with respect to the dynamic input shapes by querying the dimensions of the output bindings of the network. Here is an example that retrieves the dimensions of an output named `bar`:

```cpp
nvinfer1::Dims outDims = context->getTensorShape("bar");
if (outDims.nbDims == -1) {
```
If a dimension \( k \) is data-dependent, for example, it depends on the output of `INonZeroLayer`, `outDims.d[k]` will be -1. For more information, refer to [Dynamically Shaped Output](#) for how to deal with such outputs.

### 8.2. Named Dimensions

Both constant and runtime dimensions can be named. Naming dimensions provides two benefits:

- For runtime dimensions, error messages use the dimension’s name. For example, if an input tensor `foo` has dimensions `[n,10,m]`, it is more helpful to get an error message about `m` instead of (#2 (SHAPE foo)).
- Dimensions with the same name are implicitly equal, which can help the optimizer generate a more efficient engine, and diagnoses mismatched dimensions at runtime. For example, if two inputs have dimensions `[n,10,m]` and `[n,13]`, the optimizer knows the lead dimensions are always equal, and accidentally use of the engine with mismatched values for `n` will be reported as an error.

You can use the same name for both constant and runtime dimensions as long as they are always equal at runtime.

The following syntax examples sets the name of the third dimension of tensor to `m`.

**C++**
```
tensor.setDimensionName(2, "m")
```

**Python**
```
tensor.set_dimension_name(2, "m")
```

There are corresponding methods to get a dimensions name:

**C++**
```
tensor.getDimensionName(2) // returns the name of the third dimension of tensor, or nullptr if it does not have a name.
```

**Python**
```
tensor.get_dimension_name(2) # returns the name of the third dimension of tensor, or None if it does not have a name.
```

When the input network is imported from an ONNX file, the ONNX parser automatically sets the dimension names using the names in the ONNX file. Therefore, if two dynamic dimensions are expected to be equal at runtime, specify the same name for these dimensions when exporting the ONNX file.
8.3. Dimension Constraint using IAssertionLayer

Sometimes, two dynamic dimensions are not equal but are guaranteed to be equal at runtime. Letting TensorRT know they are equal can help it build a more efficient engine. There are two ways to convey the equality constraint to TensorRT:

- Give the dimensions the same name, as described in Named Dimensions.
- Use IAssertionLayer to express the constraint. This technique is more general since it can convey trickier equalities.

For example, if the first dimension of tensor A is guaranteed to be one more than the first dimension of tensor B, then the constraint can be established by:

**C++**

```cpp
// Assumes A and B are ITensor* and n is a INetworkDefinition.
auto shapeA = n.addShape(*A)->getOutput(0);
auto firstDimOfA = n.addSlice(*shapeA, Dims{1, {0}}, Dims{1, {1}}, Dims{1, {1}})->getOutput(0);
auto shapeB = n.addShape(*B)->getOutput(0);
auto firstDimOfB = n.addSlice(*shapeB, Dims{1, {0}}, Dims{1, {1}}, Dims{1, {1}})->getOutput(0);
static int32_t const oneStorage{1};
auto one = n.addConstant(Dims{1, {1}}, Weights{DataType::kINT32, &oneStorage, 1})->getOutput(0);
auto firstDimOfBPlus1 = n.addElementWise(*firstDimOfB, *one, ElementWiseOperation::kSUM)->getOutput(0);
auto areEqual = n.addElementWise(*firstDimOfA, firstDimOfBPlus1, ElementWiseOperation::kEQUAL)->getOutput(0);
n.addAssertion(*areEqual, "oops");
```

**Python**

```python
# Assumes `a` and `b` are ITensors and `n` is an INetworkDefinition
shape_a = n.add_shape(a).get_output(0)
first_dim_of_a = n.add_slice(shape_a, (0, ), (1, ), (1, )).get_output(0)
shape_b = n.add_shape(b).get_output(0)
first_dim_of_b = n.add_slice(shape_b, (0, ), (1, ), (1, )).get_output(0)
one = n.add_constant((1, ), np.ones((1, ), dtype=np.int32)).get_output(0)
first_dim_of_b_plus_1 = n.add_elementwise(first_dim_of_b, one,
trt.ElementWiseOperation.SUM).get_output(0)
are_equal = n.add_elementwise(first_dim_of_a, first_dim_of_b_plus_1,
trt.ElementWiseOperation.EQUAL).get_output(0)
n.add_assertion(are_equal, "oops")
```

If the dimensions violate the assertion at runtime, TensorRT will throw an error.

8.4. Optimization Profiles

An optimization profile describes a range of dimensions for each network input and the dimensions that the auto-tuner will use for optimization. When using runtime dimensions, you must create at least one optimization profile at build time. Two profiles can specify disjoint or overlapping ranges.

For example, one profile might specify a minimum size of \([3, 100, 200]\), a maximum size of \([3, 200, 300]\), and optimization dimensions of \([3, 150, 250]\) while another profile
might specify min, max and optimization dimensions of \([3, 200, 100], [3, 300, 400],\) and \([3, 250, 250]\).

Note: Based on the dimensions specified by the min, max, and opt parameters, the memory usage for different profiles can change dramatically. There are some operations that have tactics that only work for \(\text{MIN=OPT=MAX}\), so when these values differ, the tactic is disabled.

To create an optimization profile, first construct an \(\text{IOptimizationProfile}\). Then set the min, optimization, and max dimensions, and add it to the network configuration. The shapes defined by the optimization profile must define valid input shapes for the network. Here are the calls for the first profile mentioned previously for an input \(\text{foo}\):

**C++**

```cpp
IOptimizationProfile* profile = builder.createOptimizationProfile();
profile->setDimensions("foo", OptProfileSelector::kMIN, Dims3(3,100,200);
profile->setDimensions("foo", OptProfileSelector::kOPT, Dims3(3,150,250);
profile->setDimensions("foo", OptProfileSelector::kMAX, Dims3(3,200,300);
config->addOptimizationProfile(profile)
```

**Python**

```python
profile = builder.create_optimization_profile();
profile.set_shape("foo", (3, 100, 200), (3, 150, 250), (3, 200, 300))
config.add_optimization_profile(profile)
```

At runtime, you must set an optimization profile before setting input dimensions. Profiles are numbered in the order that they were added, starting at 0. Note that each execution context must use a separate optimization profile.

To choose the first optimization profile in the example, use:

**C++**

```cpp
context.setOptimizationProfileAsync(0, stream)
```

where \(\text{stream}\) is the CUDA stream that is used for the subsequent \(\text{enqueue()}, \text{enqueueV2()}, \text{or enqueueV3()}\) invocation in this context.

**Python**

```python
context.set_optimization_profile_async(0, stream)
```

If the associated CUDA engine has dynamic inputs, the optimization profile must be set at least once with a unique profile index that is not used by other execution contexts that are not destroyed. For the first execution context that is created for an engine, profile 0 is chosen implicitly.

\(\text{setOptimizationProfileAsync()}\) can be called to switch between profiles. It must be called after any \(\text{enqueue()}, \text{enqueueV2()}, \text{or enqueueV3()}\) operations finish in the current context. When multiple execution contexts run concurrently, it is allowed to switch to a profile that was formerly used but already released by another execution context with different dynamic input dimensions.

\(\text{setOptimizationProfileAsync()}\) function replaces the now deprecated version of the API \(\text{setOptimizationProfile()}\). Using \(\text{setOptimizationProfile()}\) to switch between optimization profiles can cause GPU memory copy operations in the subsequent \(\text{enqueue()}\) or \(\text{enqueueV2()}\) operations. To avoid these calls during enqueue, use \(\text{setOptimizationProfileAsync()}\) API instead.
8.5. Dynamically Shaped Output

If an output of a network has a dynamic shape, there are several strategies available to allocate the output memory.

If the dimensions of the output are computable from the dimensions of inputs, use `IExecutionContext::getTensorShape()` to get the dimensions of the output, after providing dimensions of the input tensors and [Shape Tensor I/O (Advanced)](https://docs.nvidia.com/deeplearning/sdk/tensorrt/index.html#shape-tensor-io). Use the `IExecutionContext::inferShapes()` method to check if you forgot to supply the necessary information.

Otherwise, or if you do not know if the dimensions of the output are computable in advance or calling `enqueueV3`, associate an IOutputAllocator with the output. More specifically:

1. Derive your own allocator class from `IOutputAllocator`.
2. Override the `reallocateOutput` and `notifyShape` methods. TensorRT calls the first when it needs to allocate the output memory, and the second when it knows the output dimensions. For example, the memory for the output of `INonZeroLayer` is allocated before the layer runs.

Here is an example derived class:

```cpp
class MyOutputAllocator : nvinfer1::IOutputAllocator
{
public:
    void* reallocateOutput(char const* tensorName, void* currentMemory, uint64_t size, uint64_t alignment) override
    {
        // Allocate the output. Remember it for later use.
        outputPtr = ... depends on strategy, as discussed later...
        return outputPtr;
    }

    void notifyShape(char const* tensorName, Dims const& dims)
    {
        // Remember output dimensions for later use.
        outputDims = dims;
    }

    // Saved dimensions of the output
    Dims outputDims{};

    // nullptr if memory could not be allocated
    void* outputPtr{nullptr};
};
```

Here's an example of how it might be used:

```cpp
std::unordered_map<std::string, MyOutputAllocator> allocatorMap;
for (const char* name : names of outputs) {
    Dims extent = context->getTensorShape(name);
    void* ptr;
    if (engine->getTensorLocation(name) == TensorLocation::kDEVICE)
    {
        if (extent.d contains a -1)
        {
```
Several strategies can be used for implementing `reallocateOutput`:

A
Defer allocation until the size is known. Do not call `IE::setTensorAddress`, or call it with a `nullptr` for the tensor address.

B
Preallocate enough memory, based on what `IE::getMaxOutputSize` reports as an upper bound. That guarantees that the engine will not fail for lack of sufficient output memory, but the upper bound may be so high as to be useless.

C
Preallocate enough memory based on experience, use `IE::setTensorAddress` to tell TensorRT about it. Make `reallocateOutput` return `nullptr` if the tensor does not fit, which will cause the engine to fail gracefully.

D
Preallocate memory as in C, but have `reallocateOutput` return a pointer to a bigger buffer if there is a fit problem. This increases the output buffer as needed.

E
Defer allocation until the size is known, like A. Then, attempt to recycle that allocation in subsequent calls until a bigger buffer is requested, and then increase it like in D.

Here’s an example derived class that implements E:

```cpp
class FancyOutputAllocator : nvinfer1::IOutputAllocator
{
public:
    void reallocateOutput(
        char const* tensorName, void* currentMemory,
        uint64_t size, uint64_t alignment) override
    {
        if (size > outputSize)
        {
            // Need to reallocate
            cudaFree(outputPtr);
            outputPtr = nullptr;
            outputSize = 0;
            if (cudaMalloc(&outputPtr, size) == cudaSuccess)
            {
                outputSize = size;
            }
        }
        // If the cudaMalloc fails, outputPtr=nullptr, and engine
        // gracefully fails.
        return outputPtr;
    }

    void notifyShape(char const* tensorName, Dims const& dims)
    {
    }

    void allocate(
        char const* tensorName, void* currentMemory,
        uint64_t size, uint64_t alignment)
    {
        if (size > outputSize)
        {
            // Need to reallocate
            cudaFree(outputPtr);
            outputPtr = nullptr;
            outputSize = 0;
            if (cudaMalloc(&outputPtr, size) == cudaSuccess)
            {
                outputSize = size;
            }
        }
        // If the cudaMalloc fails, outputPtr=nullptr, and engine
        // gracefully fails.
        return outputPtr;
    }

    void reallocateOutput(
        char const* tensorName, void* currentMemory,
        uint64_t size, uint64_t alignment) override
    {
        if (size > outputSize)
        {
            // Need to reallocate
            cudaFree(outputPtr);
            outputPtr = nullptr;
            outputSize = 0;
            if (cudaMalloc(&outputPtr, size) == cudaSuccess)
            {
                outputSize = size;
            }
        }
        // If the cudaMalloc fails, outputPtr=nullptr, and engine
        // gracefully fails.
        return outputPtr;
    }

    void notifyShape(char const* tensorName, Dims const& dims)
    {
    }
};
```
// Remember output dimensions for later use.
outputDims = dims;
}

// Saved dimensions of the output tensor
Dims outputDims{};

// nullptr if memory could not be allocated
void* outputPtr{nullptr};

// Size of allocation pointed to by output
uint64_t outputSize{0};

~FancyOutputAllocator() override
{
    cudaFree(outputPtr);
}
};

8.5.1. Looking up Binding Indices for Multiple Optimization Profiles

You can skip this section if using `enqueueV3` instead of the deprecated `enqueueV2`, because the name-based methods such as `IExecutionContext::setTensorAddress` expect no profile suffix.

In an engine built from multiple profiles, there are separate binding indices for each profile. The names of I/O tensors for the \( K \)th profile have \([profile \ K]\) appended to them, with \( K \) written in decimal. For example, if the INetworkDefinition had the name "foo", and `bindingIndex` refers to that tensor in the optimization profile with index 3, `engine.getBindingName(bindingIndex)` returns "foo [profile 3]".

Likewise, if using `ICudaEngine::getBindingIndex(name)` to get the index for a profile \( K \) beyond the first profile (\( K=0 \)), append "[profile \ K]" to the name used in the INetworkDefinition. For example, if the tensor was called "foo" in the INetworkDefinition, then `engine.getBindingIndex("foo [profile 3]")` returns the binding index of Tensor "foo" in optimization profile 3.

Always omit the suffix for \( K=0 \).

8.5.2. Bindings For Multiple Optimization Profiles

This section explains the deprecated interface `enqueueV2` and its binding indices. The newer interface `enqueueV3` does away with binding indices.

Consider a network with four inputs, one output, with three optimization profiles in the IBuilderConfig. The engine has 15 bindings, five for each optimization profile, conceptually organized as a table:
Each row is a profile. Numbers in the table denote binding indices. The first profile has binding indices 0..4, the second has 5..9, and the third has 10..14.

The interfaces have an "auto-correct" for the case that the binding belongs to the first profile, but another profile was specified. In that case, TensorRT warns about the mistake and then chooses the correct binding index from the same column.

For the sake of backward semi-compatibility, the interfaces have an "auto-correct" in the scenario where the binding belongs to the first profile, but another profile was specified. In this case, TensorRT warns about the mistake and then chooses the correct binding index from the same column.

8.6. Layer Extensions For Dynamic Shapes

Some layers have optional inputs that allow specifying dynamic shape information; IShapeLayer can be used for accessing the shape of a tensor at runtime. Furthermore, some layers allow calculating new shapes. The next section goes into semantic details and restrictions. Here is a summary of what you might find useful in conjunction with dynamic shapes.

IShapeLayer outputs a 1D tensor containing the dimensions of the input tensor. For example, if the input tensor has dimensions \([2,3,5,7]\), the output tensor is a four-element 1D tensor containing \([2,3,5,7]\). If the input tensor is a scalar, it has dimensions \([\]\), and the output tensor is a zero-element 1D tensor containing \([\]\).

IResizeLayer accepts an optional second input containing the desired dimensions of the output.

IShuffleLayer accepts an optional second input containing the reshape dimensions before the second transpose is applied. For example, the following network reshares a tensor \(Y\) to have the same dimensions as \(X\):

C++
```cpp
auto* reshape = networkDefinition.addShuffle(Y);
reshape.setInput(1, networkDefintion.addShape(X)->getOutput(0));
```

Python
```python
reshape = network_definition.add_shuffle(y)
reshape.set_input(1, network_definition.add_shape(X).get_output(0))
```
ISliceLayer accepts an optional second, third, and fourth input containing the start, size, and stride.

IConcatenationLayer, IElementWiseLayer, IGatherLayer, IIdentityLayer, and IReduceLayer can be used to do calculations on shapes and create new shape tensors.

8.7. Restrictions For Dynamic Shapes

The following layer restrictions arise because the layer’s weights have a fixed size:

- IConvolutionLayer and IDeconvolutionLayer require that the channel dimension be a build time constant.
- IFullyConnectedLayer requires that the last three dimensions be build-time constants.
- Int8 requires that the channel dimension be a build time constant.
- Layers accepting additional shape inputs (IResizeLayer, IShuffleLayer, ISliceLayer) require that the additional shape inputs be compatible with the dimensions of the minimum and maximum optimization profiles as well as with the dimensions of the runtime data input; otherwise, it can lead to either a build-time or runtime error.

Values that must be build-time constants do not have to be constants at the API level. TensorRT's shape analyzer does element by element constant propagation through layers that do shape calculations. It is sufficient that the constant propagation discovers that a value is a build time constant.

For more information regarding layers, refer to the NVIDIA TensorRT Operator’s Reference.

8.8. Execution Tensors Versus Shape Tensors

TensorRT 8.5 largely erases the distinctions between execution tensors and shape tensors. However, if designing a network or analyzing performance, it may help to understand the internals and where internal synchronization is incurred.

Engines using dynamic shapes employ a ping-pong execution strategy.

1. Compute the shapes of tensors on the CPU until a shape requiring GPU results is reached.
2. Stream work to the GPU until out of work or an unknown shape is reached if the latter, synchronize and go back to step 1.

An execution tensor is a traditional TensorRT tensor. A shape tensor is a tensor that is related to shape calculations. It must have type Int32, Float, or Bool, its shape must be determinable at build time, and it must have no more than 64 elements. Refer to Shape Tensor I/O (Advanced) for additional restrictions for shape tensors at network I/O
boundaries. For example, there is an `IShapeLayer` whose output is a 1D tensor containing
the dimensions of the input tensor. The output is a shape tensor. `IShuffleLayer` accepts
an optional second input that can specify reshaping dimensions. The second input must
be a shape tensor.

Some layers are “polymorphic” with respect to the kinds of tensors that they handle. For
example, `IElementWiseLayer` can sum two INT32 execution tensors or sum two INT32
shape tensors. The type of tensor depends on its ultimate use. If the sum is used to
reshape another tensor, then it is a “shape tensor.”

When TensorRT needs a shape tensor, but the tensor has been classified as an execution
tensor, the runtime has to copy the tensor from the GPU to the CPU, which incurs
synchronization overhead.

### 8.8.1. Formal Inference Rules

The formal inference rules used by TensorRT for classifying tensors are based on a type-
inference algebra. Let \( E \) denote an execution tensor and \( S \) denote a shape tensor.

`IActivationLayer` has the signature:

\[
\text{IActivationLayer} : E \to E
\]

since it takes an execution tensor as an input and an execution tensor as an output.

`IElementWiseLayer` is polymorphic in this respect, with two signatures:

\[
\text{IElementWiseLayer} : S \times S \to S, E \times E \to E
\]

For brevity, let us adopt the convention that \( t \) is a variable denoting either class of
tensor, and all \( t \) in a signature refers to the same class of tensor. Then, the two previous
signatures can be written as a single polymorphic signature:

\[
\text{IElementWiseLayer} : t \times t \to t
\]

The two-input `IShuffleLayer` has a shape tensor as the second input and is polymorphic
with respect to the first input:

\[
\text{IShuffleLayer (two inputs)} : t \times S \to t
\]

`IConstantLayer` has no inputs, but can produce a tensor of either kind, so its signature
is:

\[
\text{IConstantLayer} : \to t
\]

The signature for `IShapeLayer` allows all four possible combinations \( E \to E, E \to S, S \to E, \) and
\( S \to S \), so it can be written with two independent variables:

\[
\text{IShapeLayer} : t_1 \to t_2
\]

Here is the complete set of rules, which also serves as a reference for which layers can be
used to manipulate shape tensors:

\[
\begin{align*}
\text{IAssertionLayer} : S \to S \\
\text{IConcatenationLayer} : t \times t \times \ldots \to t \\
\text{IIIfConditionalInputLayer} : t \to t \\
\text{IIIfConditionalOutputLayer} : t \to t \\
\text{IConstantLayer} : \to t \\
\text{IActivationLayer} : t \to t \\
\text{IElementWiseLayer} : t \times t \to t \\
\text{IFillLayer} : S \to t \\
\text{IFillLayer} : S \times E \times E \to E \\
\text{IGatherLayer} : t \times t \to t \\
\text{IIdentityLayer} : t \to t \\
\text{IReduceLayer} : t \to t \\
\text{IResizeLayer (one input)} : E \to E \\
\text{IResizeLayer (two inputs)} : E \times S \to E
\end{align*}
\]
ISelectLayer: \( t \times t \times t \to t \)
IShapeLayer: \( t_1 \to t_2 \)
IShuffleLayer (one input): \( t \to t \)
IShuffleLayer (two inputs): \( t \times S \to t \)
ISliceLayer (one input): \( t \to t \)
ISliceLayer (two inputs): \( t \times S \to t \)
ISliceLayer (three inputs): \( t \times S \times S \to t \)
ISliceLayer (four inputs): \( t \times S \times S \times S \to t \)
IUnaryLayer: \( t \to t \)
all other layers: \( E \times ... \to E \times ... \)

Because an output can be the input of more than one subsequent layer, the inferred "types" are not exclusive. For example, an IConstantLayer might feed into one use that requires an execution tensor and another use that requires a shape tensor. The output of IConstantLayer is classified as both and can be used in both phase 1 and phase 2 of the two-phase execution.

The requirement that the size of a shape tensor be known at build time limits how ISliceLayer can be used to manipulate a shape tensor. Specifically, if the third parameter, which specifies the size of the result, and is not a build-time constant, the length of the resulting tensor is unknown at build time, breaking the restriction that shape tensors have constant shapes. The slice will still work, but will incur synchronization overhead at runtime because the tensor is considered an execution tensor that has to be copied back to the CPU to do further shape calculations.

The rank of any tensor has to be known at build time. For example, if the output of ISliceLayer is a 1D tensor of unknown length that is used as the reshape dimensions for IShuffleLayer, the output of the shuffle would have unknown rank at build time, and hence such a composition is prohibited.

TensorRT’s inferences can be inspected using methods ITensor::isShapeTensor(), which returns true for a shape tensor, and ITensor::isExecutionTensor(), which returns true for an execution tensor. Build the entire network first before calling these methods because their answer can change depending on what uses of the tensor have been added.

For example, if a partially built network sums two tensors, \( T_1 \) and \( T_2 \), to create tensor \( T_3 \), and none are yet needed as shape tensors, isShapeTensor() returns false for all three tensors. Setting the second input of IShuffleLayer to \( T_3 \) would cause all three tensors to become shape tensors because IShuffleLayer requires that its second optional input be a shape tensor, and if the output of IElementWiseLayer is a shape tensor, its inputs are too.

### 8.9. Shape Tensor I/O (Advanced)

Sometimes the need arises to use a shape tensor as a network I/O tensor. For example, consider a network consisting solely of an IShuffleLayer. TensorRT inferences the second input is a shape tensor. ITensor::isShapeTensor returns true for it. Because it is an input shape tensor, TensorRT requires two things for it:

- At build time: the optimization profile values of the shape tensor.
- At run time: the values of the shape tensor.
The shape of an input shape tensor is always known at build time. It is the values that must be described since they can be used to specify the dimensions of execution tensors.

The optimization profile values can be set using `IOptimizationProfile::setShapeValues`. Analogous to how min, max, and optimization dimensions must be supplied for execution tensors with runtime dimensions, min, max, and optimization values must be provided for shape tensors at build time.

The corresponding runtime method is `IExecutionContext::setTensorAddress`, which tells TensorRT where to look for the shape tensor values.

Because the inference of “execution tensor” vs “shape tensor” is based on ultimate use, TensorRT cannot infer whether a network output is a shape tensor. You must tell it using the method `INetworkDefinition::markOutputForShapes`.

Besides letting you output shape information for debugging, this feature is useful for composing engines. For example, consider building three engines, one each for sub-networks A, B, C, where a connection from A to B or B to C might involve a shape tensor. Build the networks in reverse order: C, B, and A. After constructing network C, you can use `ITensor::isShapeTensor` to determine if an input is a shape tensor, and `INetworkDefinition::markOutputForShapes` to mark the corresponding output tensor in network B. Then check which inputs of B are shape tensors and mark the corresponding output tensor in network A.

Shape tensors at network boundaries must have type `Int32`. They cannot have type `Float` or `Bool`. A workaround for `Bool` is to use `Int32` for the I/O tensor, with zeros and ones, and convert to/from `Bool` using `IIdentityLayer`.

At runtime, whether a tensor is an I/O shape tensor can be determined via method `ICudaEngine::isShapeInferenceIO()`.

## 8.10. INT8 Calibration with Dynamic Shapes

To run INT8 calibration for a network with dynamic shapes, a calibration optimization profile must be set. Calibration is performed using kOPT values of the profile. Calibration input data size must match this profile.

To create a calibration optimization profile, first, construct an `IOptimizationProfile` the same way as it is done for a general optimization profile. Then set the profile to the configuration:

```cpp
c++
config->setCalibrationProfile(profile)
```

```python
Python
config.set_calibration_profile(profile)
```

The calibration profile must be valid or be `nullptr`. `kMIN` and `kMAX` values are overwritten by `kOPT`. To check the current calibration profile, use `IBuilderConfig::getCalibrationProfile`. 
This method returns a pointer to the current calibration profile or nullptr if the calibration profile is unset. `getBatchSize()` calibrator method must return 1 when running calibration for a network with dynamic shapes.

**Note:** If the calibration optimization profile is not set, the first network optimization profile is used as a calibration optimization profile.
Chapter 9. Extending TensorRT with Custom Layers

NVIDIA TensorRT supports many types of layers and its functionality is continually extended; however, there can be cases in which the layers supported do not cater to the specific needs of a model. In such cases, TensorRT can be extended by implementing custom layers, often referred to as plugins.

TensorRT contains plugins that can be loaded into your application. For a list of open-source plugins, refer to GitHub: TensorRT plugins.

To use TensorRT plugins in your application, the libnvinfer_plugin.so (nvinfer_plugin.dll on Windows) library must be loaded, and all plugins must be registered by calling initLibNvInferPlugins in your application code. For more information about these plugins, refer to the NvInferPlugin.h file for reference.

If these plugins do not meet your needs, you can write and add your own.

9.1. Adding Custom Layers Using the C++ API

You can implement a custom layer by deriving from one of TensorRT’s plugin base classes. Derive your plugin class from one of the base classes for plugins. They have varying expressive power with respect to supporting I/O with different types/formats or networks with dynamic shapes. The following table summarizes the base classes, ordered from least expressive to most expressive.

Note: If a plugin is intended for general use, provide an FP32 implementation in order to allow it to properly operate with any network.
Table 3. Base Classes, Ordered from Least Expressive to Most Expressive

<table>
<thead>
<tr>
<th>Class</th>
<th>Introduced in TensorRT version?</th>
<th>Mixed I/O formats/types</th>
<th>Dynamic shapes?</th>
<th>Supports implicit/explicit batch mode?</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPluginV2Ext</td>
<td>5.1 (deprecated since TensorRT 8.5)</td>
<td>Limited</td>
<td>No</td>
<td>Both implicit and explicit batch modes</td>
</tr>
<tr>
<td>IPluginV2IOExt</td>
<td>6.0.1</td>
<td>General</td>
<td>No</td>
<td>Both implicit and explicit batch modes</td>
</tr>
<tr>
<td>IPluginV2DynamicExt</td>
<td>6.0.1</td>
<td>General</td>
<td>Yes</td>
<td>Explicit batch mode only</td>
</tr>
</tbody>
</table>

In order to use a plugin in a network, you must first register it with TensorRT’s PluginRegistry (C++, Python). Rather than registering the plugin directly, you register an instance of a factory class for the plugin, derived from PluginCreator (C++, Python). The plugin creator class also provides other information about the plugin: its name, version, and plugin field parameters.

There are two ways that you can register plugins with the registry:

- TensorRT provides a macro REGISTER_TENSORRT_PLUGIN that statically registers the plugin creator with the registry. Note that REGISTER_TENSORRT_PLUGIN always registers the creator under the default namespace (“”).
- Dynamically register by creating your own entry-point similar to initLibNvInferPlugins and calling registerCreator on the plugin registry. This is preferred over static registration as it offers a potentially lower memory footprint and allows plugins to be registered under a unique namespace. This ensures that there are no name collisions during build time across different plugin libraries.

Calling IPluginCreator::createPlugin() returns a plugin object of type IPluginV2. You can add a plugin to the TensorRT network using addPluginV2(), which creates a network layer with the given plugin.

For example, you can add a plugin layer to your network as follows:

```c++
// Look up the plugin in the registry
auto creator = getPluginRegistry()->getPluginCreator(pluginName, pluginVersion);
const PluginFieldCollection* pluginFC = creator->getFieldNames();
// Populate the fields parameters for the plugin layer
PluginFieldCollection *pluginData = parseAndFillFields(pluginFC, layerFields);
// Create the plugin object using the layerName and the plugin meta data
IPluginV2 *pluginObj = creator->createPlugin(layerName, pluginData);
// Add the plugin to the TensorRT network
auto layer = network.addPluginV2(&inputs[0], int(inputs.size()), pluginObj);
... (build rest of the network and serialize engine)
// Destroy the plugin object
pluginObj->destroy();
```
During serialization, the TensorRT engine internally stores the plugin type, plugin version, and namespace (if it exists) for all IPluginV2 type plugins. During deserialization, TensorRT looks up the plugin creator from the plugin registry and calls IPluginCreator::deserializePlugin(). When the engine is deleted, the clone of the plugin object, created during engine build, is destroyed by the engine by calling the IPluginV2::destroy() method. It is your responsibility to ensure the plugin object you created is freed after it is added to the network.

9.1.1. Example: Adding a Custom Layer with Dynamic Shape Support Using C++

To support dynamic shapes, your plugin must be derived from IPluginV2DynamicExt.

BarPlugin is a plugin with two inputs and two outputs where:

- The first output is a copy of the second input.
- The second output is the concatenation of both inputs, along the first dimension, and all types/formats must be the same and be linear formats.

BarPlugin must be derived as follows:
```cpp
class BarPlugin : public IPluginV2DynamicExt
{
    ...override virtual methods inherited from IPluginV2DynamicExt.
};
```

The four methods that are affected by dynamic shapes are:

- `getOutputDimensions`
- `supportsFormatCombination`
- `configurePlugin`
- `enqueue`
The override for `getOutputDimensions` returns symbolic expressions for the output dimensions in terms of the input dimensions. You can build the expressions from the expressions for the inputs, using the `IExprBuilder` passed into `getOutputDimensions`. In the example, no new expression has to be built for case 1 because the dimensions of the second output are the same as the dimensions of the first input.

```cpp
DimsExprs BarPlugin::getOutputDimensions(int outputIndex, const DimsExprs* inputs, int nbInputs, IExprBuilder& exprBuilder)
{
    switch (outputIndex)
    {
    case 0:
        {
            // First dimension of output is sum of input
            // first dimensions.
            DimsExprs output(inputs[0]);
            output.d[0] = exprBuilder.operation(DimensionOperation::kSUM, inputs[0].d[0], inputs[1].d[0]);
            return output;
        }
    case 1:
        return inputs[0];
    default:
        throw std::invalid_argument("invalid output");
    }
}
```

The override for `supportsFormatCombination` must indicate whether a format combination is allowed. The interface indexes the inputs/outputs uniformly as “connections,” starting at 0 for the first input, then the rest of the inputs in order, followed by numbering the outputs. In the example, the inputs are connections 0 and 1, and the outputs are connections 2 and 3.

TensorRT uses `supportsFormatCombination` to ask whether a given combination of formats/types is okay for a connection, given formats/types for lesser indexed connections. So the override can assume that lesser indexed connections have already been vetted and focus on the connection with index `pos`.

```cpp
bool BarPlugin::supportsFormatCombination(int pos, const PluginTensorDesc* inOut, int nbInputs, int nbOutputs) override
{
    assert(0 <= pos && pos < 4);
    const auto* in = inOut;
    const auto* out = inOut + nbInputs;
    switch (pos)
    {
    case 0: return in[0].format == TensorFormat::kLINEAR;
    case 1: return in[1].type == in[0].type &&
                in[1].format == TensorFormat::kLINEAR;
    case 2: return out[0].type == in[0].type &&
                out[0].format == TensorFormat::kLINEAR;
    case 3: return out[1].type == in[0].type &&
                out[1].format == TensorFormat::kLINEAR;
    }
    throw std::invalid_argument("invalid connection number");
}
```
The local variables \texttt{in} and \texttt{out} here allow inspecting \texttt{inOut} by input or output number instead of connection number.

\textbf{Important:} The override inspects the format/type for a connection with an index less than \texttt{pos}, but must never inspect the format/type for a connection with an index greater than \texttt{pos}. The example uses case 3 to check connection 3 against connection 0, and not use case 0 to check connection 0 against connection 3.

TensorRT uses \texttt{configurePlugin} to set up a plugin at runtime. This plugin does not need \texttt{configurePlugin} to do anything, so it is a no-op:

```cpp
def BarPlugin::configurePlugin(const DynamicPluginTensorDesc* in, int nbInputs, const DynamicPluginTensorDesc* out, int nbOutputs)
{
}
```

If the plugin needs to know the minimum or maximum dimensions it might encounter, it can inspect the field \texttt{DynamicPluginTensorDesc::min} or \texttt{DynamicPluginTensorDesc::max} for any input or output. Format and build-time dimension information can be found in \texttt{DynamicPluginTensorDesc::desc}. Any runtime dimensions appear as -1. The actual dimension is supplied to \texttt{BarPlugin::enqueue}.

Finally, the override \texttt{BarPlugin::enqueue} has to do the work. Since shapes are dynamic, \texttt{enqueue} is handed a \texttt{PluginTensorDesc} that describes the actual dimensions, type, and format of each input and output.

### 9.1.2. Example: Adding a Custom Layer with INT8 I/O Support Using C++

\texttt{PoolPlugin} is a plugin to demonstrate how to extend INT8 I/O for the custom-pooling layer. The derivation is as follows:

```cpp
class PoolPlugin : public IPluginV2IOExt
{
    ...override virtual methods inherited from IPluginV2IOExt.
};
```

Most of the pure virtual methods are common to plugins. The main methods that affect INT8 I/O are:

- \texttt{supportsFormatCombination}
- \texttt{configurePlugin}
- \texttt{enqueue}

The override for \texttt{supportsFormatCombination} must indicate which INT8 I/O combination is allowed. The usage of this interface is similar to \texttt{Example: Adding a Custom Layer with Dynamic Shape Support Using C++}. In this example, the supported I/O tensor format is linear CHW with FP32, FP16, or INT8 data type, but the I/O tensor must have the same data type.

```cpp
bool PoolPlugin::supportsFormatCombination(int pos, const PluginTensorDesc* inOut, int nbInputs, int nbOutputs) const override
```
{  
    assert(nbInputs == 1 && nbOutputs == 1 && pos < nbInputs + nbOutputs);
    bool condition = inOut[pos].format == TensorFormat::kLINEAR;
    condition &= ((inOut[pos].type == DataType::kFLOAT) ||
                   (inOut[pos].type == DataType::kHALF) ||
                   (inOut[pos].type == DataType::kINT8));
    condition &= inOut[pos].type == inOut[0].type;
    return condition;
}

Important:

‣  If INT8 calibration must be used with a network with INT8 I/O plugins, the plugin must
    support FP32 I/O as TensorRT uses FP32 to calibrate the graph.
‣  If the FP32 I/O variant is not supported or INT8 calibration is not used, all required
    INT8 I/O tensors scales must be set explicitly.
‣  Calibration cannot determine the dynamic range of a plugin internal tensor. Plugins
    that operate on quantized data must calculate their own dynamic range for internal
    tensors.

TensorRT invokes configurePlugin method to pass the information to the plugin
through PluginTensorDesc, which are stored as member variables, serialized and
deserialized.

```cpp
void PoolPlugin::configurePlugin(const PluginTensorDesc* in, int nbInput, const
                                 PluginTensorDesc* out, int nbOutput)
{
    ...
    mPoolingParams.mC = mInputDims.d[0];
    mPoolingParams.mH = mInputDims.d[1];
    mPoolingParams.mW = mInputDims.d[2];
    mPoolingParams.mP = mOutputDims.d[1];
    mPoolingParams.mQ = mOutputDims.d[2];
    mInHostScale = in[0].scale >= 0.0F ? in[0].scale : -1.0F;
    mOutHostScale = out[0].scale >= 0.0F ? out[0].scale : -1.0F;
}
```

Where INT8 I/O scales per tensor can be obtained from PluginTensorDesc::scale.

Finally, the override UffPoolPluginV2::enqueue has to do the work. It includes a
collection of core algorithms to execute the custom layer at runtime by using the actual
batch size, inputs, outputs, cuDNN stream, and the information configured.

```cpp
int PoolPlugin::enqueue(int batchSize, const void* const* inputs, void** outputs, void*
                        workspace, cudaStream_t stream)
{
    ...
    CHECK(cudnnPoolingForward(mCudnn, mPoolingDesc, &kONE, mSrcDescriptor, input, &kZERO,
                               mDstDescriptor, output));
    ...
    return 0;
}
```
9.2. Adding Custom Layers Using the Python API

Although the C++ API is the preferred language to implement custom layers, due to accessing libraries like CUDA and cuDNN, you can also work with custom layers in Python applications.

You can use the C++ API to create a custom layer, package the layer using pybind11 in Python, then load the plugin into a Python application. For more information, refer to Creating a Network Definition in Python.

The same custom layer implementation can be used for both C++ and Python.

9.2.1. Example: Adding a Custom Layer to a TensorRT Network Using Python

Custom layers can be added to any TensorRT network in Python using plugin nodes.

The Python API has a function called `add_plugin_v2` that enables you to add a plugin node to a network. The following example illustrates this. It creates a simple TensorRT network and adds a leaky ReLU plugin node by looking up the TensorRT plugin registry.

```python
import tensorrt as trt
import numpy as np
TRT_LOGGER = trt.Logger()
trt.init_libnvinfer_plugins(TRT_LOGGER, '')
PLUGIN_CREATORS = trt.get_plugin_registry().plugin_creator_list

def get_trt_plugin(plugin_name):
    plugin = None
    for plugin_creator in PLUGIN_CREATORS:
        if plugin_creator.name == plugin_name:
            lrelu_slope_field = trt.PluginField("neg_slope", np.array([0.1],
dtype=np.float32), trt.PluginFieldType.FLOAT32)
            field_collection = trt.PluginFieldCollection([lrelu_slope_field])
            plugin = plugin_creator.create_plugin(name=plugin_name,
            field_collection=field_collection)
    return plugin

def main():
    builder = trt.Builder(TRT_LOGGER)
    network = builder.create_network()
    config = builder.create_builder_config()
    config.max_workspace_size = 2**20
    input_layer = network.add_input(name="input_layer", dtype=trt.float32, shape=(1, 1))
    lrelu = network.add_plugin_v2(inputs=[input_layer], plugin=get_trt_plugin("LReLU_TRT"))
    lrelu.get_output(0).name = "outputs"
    network.mark_output(lrelu.get_output(0))
```
9.3. Using Custom Layers When Importing a Model with a Parser

The ONNX parser automatically attempts to import unrecognized nodes as plugins. If a plugin with the same `op_type` as the node is found in the plugin registry, the parser forwards the attributes of the node to the plugin creator as plugin field parameters in order to create the plugin. By default, the parser uses “1” as the plugin version and “” as the plugin namespace. This behavior can be overridden by setting a `plugin_version` and `plugin_namespace` string attribute in the corresponding ONNX node.

In some cases, you might want to modify an ONNX graph before importing it into TensorRT. For example, to replace a set of ops with a plugin node. To accomplish this, you can use the ONNX GraphSurgeon utility. For details on how to use ONNX-GraphSurgeon to replace a subgraph, refer to this example.

For more examples, refer to the onnx_packnet sample.

9.4. Plugin API Description

All new plugins should derive classes from both `IPluginCreator` and one of the plugin base classes described in Adding Custom Layers Using the C++ API. In addition, new plugins should also call the `REGISTER_TENSORRT_PLUGIN(...)` macro to register the plugin with the TensorRT plugin registry or create an `init` function equivalent to `initLibNvInferPlugins()`.

Note: Automotive safety users must use the `REGISTER_SAFE_TENSORRT_PLUGIN(...)` macro instead of `REGISTER_TENSORRT_PLUGIN(...).

9.4.1. Migrating Plugins from TensorRT 6.x or 7.x to TensorRT 8.x.x

IPluginV2 and IPluginV2Ext have been deprecated since TensorRT 8.5. Therefore, new plugins should target the IPluginV2DynamicExt or IPluginV2IOExt interfaces, and old ones refactored to use these interfaces.

The new features in IPluginV2DynamicExt are as follows:

```cpp
virtual DimsExprs getOutputDimensions(int outputIndex, const DimsExprs* inputs, int nbInputs, IExprBuilder& exprBuilder) = 0;

virtual bool supportsFormatCombination(int pos, const PluginTensorDesc* inOut, int nbInputs, int nbOutputs) = 0;

virtual void configurePlugin(const DynamicPluginTensorDesc* in, int nbInputs, const DynamicPluginTensorDesc* out, int nbOutputs) = 0;

virtual size_t getWorkspaceSize(const PluginTensorDesc* inputs, int nbInputs, const PluginTensorDesc* outputs, int nbOutputs) const = 0;
```
virtual int enqueue(const PluginTensorDesc* inputDesc, const PluginTensorDesc* outputDesc, const void* const* inputs, void* const* outputs, void* workspace, cudaStream_t stream) = 0;

The new features in IPluginV2IOExt are as follows:
virtual void configurePlugin(const PluginTensorDesc* in, int nbInput, const PluginTensorDesc* out, int nbOutput) = 0;
virtual bool supportsFormatCombination(int pos, const PluginTensorDesc* inOut, int nbInputs, int nbOutputs) const = 0;

Guidelines for migration to IPluginV2DynamicExt or IPluginV2IOExt:
- **getOutputDimensions** implements the expression for output tensor dimensions given the inputs.
- **supportsFormatCombination** checks if the plugin supports the format and datatype for the specified I/O.
- **configurePlugin** mimics the behavior of equivalent configurePlugin in IPluginV2Ext but accepts tensor descriptors.
- **getWorkspaceSize** and **enqueue** mimic the behavior of equivalent APIs in IPluginV2Ext but accept tensor descriptors.

Refer to the API description in [IPluginV2 API Description](#) for more details about the API.

### 9.4.2. IPluginV2 API Description

The following section describes the functions of the IPluginV2 class. To connect a plugin layer to neighboring layers and set up input and output data structures, the builder checks for the number of outputs and their dimensions by calling the following plugins methods.

- **getNbOutputs**
  - Used to specify the number of output tensors.

- **getOutputDimensions**
  - Used to specify the dimensions of output as a function of the input dimensions.

- **supportsFormat**
  - Used to check if a plugin supports a given data format.

- **getOutputDataType**
  - Used to get the data type of the output at a given index. The returned data type must have a format that is supported by the plugin.

Plugin layers can support the following data formats:

- **LINEAR** single-precision (FP32), half-precision (FP16), integer (INT8), and integer (INT32) tensors
- **CHW32** single-precision (FP32) and integer (INT8) tensors
- **CHW2, HWC8, HWC16, and DHWC8** half-precision (FP16) tensors
- **CHW4** half-precision (FP16), and integer (INT8) tensors

The formats are counted by PluginFormatType.

Plugins that do not compute all data in place and need memory space in addition to input and output tensors can specify the additional memory requirements with the...
getWorkspaceSize method, which is called by the builder to determine and preallocate scratch space.

During both build and inference time, the plugin layer is configured and executed, possibly multiple times. At build time, to discover optimal configurations, the layer is configured, initialized, executed, and terminated. After the optimal format is selected for a plugin, the plugin is once again configured, then it is initialized once and executed as many times as needed for the lifetime of the inference application, and finally terminated when the engine is destroyed. These steps are controlled by the builder and the engine using the following plugin methods:

configurePlugin
Communicates the number of inputs and outputs, dimensions, and datatypes of all inputs and outputs, broadcast information for all inputs and outputs, the chosen plugin format, and maximum batch size. At this point, the plugin sets up its internal state and selects the most appropriate algorithm and data structures for the given configuration.

initialize
The configuration is known at this time, and the inference engine is being created, so the plugin can set up its internal data structures and prepare for execution.

enqueue
Encapsulates the actual algorithm and kernel calls of the plugin and provides the runtime batch size, pointers to input, output, and scratch space, and the CUDA stream to be used for kernel execution.

terminate
The engine context is destroyed, and all the resources held by the plugin must be released.

clone
This is called every time a new builder, network, or engine is created that includes this plugin layer. It must return a new plugin object with the correct parameters.

destroy
Used to destroy the plugin object and other memory allocated each time a new plugin object is created. It is called whenever the builder or network or engine is destroyed.

set/getPluginNamespace
This method is used to set the library namespace that this plugin object belongs to (default can be ""). All plugin objects from the same plugin library should have the same namespace.

IPluginV2Ext supports plugins that can handle broadcast inputs and outputs. The following methods must be implemented for this feature:

canBroadcastInputAcrossBatch
This method is called for each input whose tensor is semantically broadcast across a batch. If canBroadcastInputAcrossBatch returns true (meaning the plugin can support broadcast), TensorRT does not replicate the input tensor. There is a single copy that the plugin should share across the batch. If it returns false, TensorRT replicates the input tensor so that it appears like a nonbroadcasted tensor.
isOutputBroadcastAcrossBatch

This is called for each output index. The plugin should return true the output at the given index and is broadcast across the batch.

IPluginV2IOExt

This is called by the builder before initialize(). It provides an opportunity for the layer to make algorithm choices on the basis of I/O PluginTensorDesc and the maximum batch size.

Note: Plugins based on IPluginV2 are shared at the engine level, not the execution context level, and thus such plugins that may be used simultaneously by multiple threads must manage their resources in a thread-safe manner. Plugins based on IPluginV2Ext and derivative interfaces are cloned when an ExecutionContext is created, so this is not required.

9.4.3. IPluginCreator API Description

The following methods in the IPluginCreator class are used to find and create the appropriate plugin from the plugin registry:

getPluginName

This returns the plugin name and should match the return value of IPluginExt::getPluginType.

getPluginVersion

Returns the plugin version. For all internal TensorRT plugins, this defaults to 1.

getFieldNames

To successfully create a plugin, it is necessary to know all the field parameters of the plugin. This method returns the PluginFieldCollection struct with the PluginField entries populated to reflect the field name and PluginFieldType (the data should point to nullptr).

createPlugin

This method is used to create the plugin using the PluginFieldCollection argument. The data field of the PluginField entries should be populated to point to the actual data for each plugin field entry.

Note: The data passed to the createPlugin function should be allocated by the caller and eventually freed by the caller when the program is destroyed. The ownership of the plugin object returned by the createPlugin function is passed to the caller and must be destroyed as well.

deserializePlugin

This method is called internally by the TensorRT engine based on the plugin name and version. It should return the plugin object to be used for inference. The plugin object created in this function is destroyed by the TensorRT engine when the engine is destroyed.

set/getPluginNamespace

This method is used to set the namespace that this creator instance belongs to (default can be "").
9.5. Best Practices for Custom Layers Plugin

9.5.1. Coding Guidelines for Plugins

Memory Allocation

Memory allocated in the plugin must be freed to ensure no memory leak. If resources are acquired in the `initialize()` function, they must be released in the `terminate()` function. All other memory allocations should be freed, preferably in the plugin class destructor or in the `destroy()` method. Adding Custom Layers Using the C++ API outlines this in detail and also provides some notes for best practices when using plugins.

Add Checks to Ensure Proper Configuration and Validate Inputs

A common source for unexpected plugin behavior is improper configuration (for example, invalid plugin attributes) and invalid inputs. As such, it is good practice to add checks/ assertions during the initial plugin development for cases where the plugin is not expected to work. The following are places where checks could be added:

- `createPlugin`: Plugin attributes checks
- `configurePlugin`: Input dimension checks
- `enqueue`: Input value checks

Return Null at Errors for Methods That Creates a New Plugin Object

`createPlugin`, `clone`, and `deserializePlugin` are expected to create and return new plugin objects. In these methods, make sure a null object (`nullptr` in C++) is returned in case of any error or failed check. This ensures that non-null plugin objects are not returned when the plugin is incorrectly configured.

Avoid Device Memory Allocations in `clone()`

Since `clone` is called multiple times in the builder, device memory allocations could be significantly expensive. A good practice is to do persistent memory allocations in `initialize`, copy to device when the plugin is ready-to-use (for example, in `configurePlugin`), and release in `terminate`. 
9.5.2. Using Plugins in Implicit/Explicit Batch Networks

TensorRT allows for a network to be created in either implicit batch mode or explicit batch mode (refer to Explicit Versus Implicit Batch). It is useful to remember the following regarding plugin behavior in implicit/explicit batch mode networks:

- Plugins implementing IPluginV2DynamicExt can only be added to a network configured in explicit batch mode.
- Non-IPluginV2DynamicExt plugins can be added to a network configured in either implicit or explicit batch mode.

**Important:** Even though non-IPluginV2DynamicExt plugins are compatible with explicit batch mode networks, their implementation must be independent of the type of network (implicit/explicit batch mode) in which it is expected to be used. As such, when using such plugins in explicit batch mode networks:

- The leading dimension of the first input (before being passed to the plugin) is inferred to be the batch dimension.
- TensorRT pops this first dimension identified above before inputs are passed to the plugin, and pushes it to the front of any outputs emitted by the plugin. This means that the batch dimension must not be specified in `getOutputDimensions`.

9.5.3. Communicating Shape Tensors to Plugins

The TensorRT plugin API does not support direct input of shape tensors to plugin, nor direct output. However, this limitation can be worked around with empty tensors. Use a dummy input tensor with the dimensions of interest and a zero dimension, so that the input occupies practically no space.

For example, suppose a plugin must know a 2-element 1D shape tensor value \([P, Q]\) to calculate the shape of its outputs, for example, to implement `IPluginV2DynamicExt::getOutputDimensions`. Instead of passing in the shape tensor \([P, Q]\), design the plugin to have a dummy input that is an execution tensor with dimensions \([0, P, Q]\). TensorRT will tell the plugin dimensions of the dummy input, from which the plugin can extract \([P, Q]\). Because the tensor is empty, it will occupy a tiny amount of space, just enough to give it a distinct address.

In the network, create the dummy input tensor by using a zero-stride slice, or by reshaping an empty tensor. Here are the mechanics using a zero-stride slice:

```cpp
// Shape tensor of interest. Assume it has the value [P, Q].
ITensor* pq = ...;

// Create an empty-tensor constant with dimensions [0,1,1].
// Since it's empty, the type doesn't matter, but let's assume float.
ITensor* c011 = network.addConstant({3, {0, 1, 1}}, {DataType::kFLOAT, nullptr, 0})->getOutput(0);

// Create shape tensor that has the value [0,P,Q]
static int32_t const intZero = 0;
ITensor* z = network.addConstant({1, {1}}, {DataType::kINT32, &intZero, 1})->getOutput(0);
```
ITensor* concatInputs[] = {z, pq};
IConcatenationLayer* zpq = network.addConcatenation(concatInputs, 2);
  zpq->setAxis(0);

  // Create zero-stride slice with output size [0,P,Q]
  Dims z3{3, {0, 0, 0}};
  ISliceLayer* slice = network.addSlice(*c011, z3, z3, z3);
  slice->setInput(2, *zpq->getOutput(0));

Use slice->getOutput(0) as the dummy input to the plugin.

If using IShuffleLayer to create the empty tensor, be sure to turn off special interpretation of zeros in the reshape dimensions, that is, be sure to call setZeroIsPlaceholder(false).

9.6. Plugin Shared Libraries

TensorRT contains built-in plugins that can be loaded statically into your application.

You can explicitly register custom plugins with TensorRT using the REGISTER_TENSORRT_PLUGIN and registerCreator interfaces (refer to Adding Custom Layers Using the C++ API). However, you may want TensorRT to manage registration of a plugin library, and, in particular, serialize plugin libraries with the plan file so they are automatically loaded when the engine is created. This can be especially useful when you want to include the plugins in a version compatible engine, so that you do not need to manage them after building the engine. In order to take advantage of this, you can build shared libraries with specific entry points recognized by TensorRT.

9.6.1. Generating Plugin Shared Libraries

To create a shared library for plugins, the library must have the following public symbols defined:

    extern "C" void setLoggerFinder(ILoggerFinder& finder);
    extern "C" IPluginCreator* const* getPluginCreators(int32_t& nbCreators) const;

Note extern "C" above is only used to prevent name mangling, and the methods themselves should be implemented in C++. Consult your compiler’s ABI documentation for more details.

setLoggerFinder() should set a global pointer of ILoggerFinder in the library for logging in the plugin code. getPluginCreators() returns a list of plugin creators your library contains. An example of implementation of these entry points can be found in plugin/common/vfcCommon.h/cpp.

To serialize your plugin libraries with your engine plan, provide the plugin libraries paths to TensorRT using setPluginsToSerialize() in BuilderConfig.

When building version compatible engines, you may also want to package plugins in the plan. The packaged plugins will have the same lifetime as the engine and will be automatically registered/deregistered when running the engine.
9.6.2. Using Plugin Shared Libraries

After building your shared libraries, you can configure the builder to serialize the libraries with the engine. Next time, when you load the engine into TensorRT, the serialized plugin libraries will be loaded and registered automatically.

First, you will need to load the plugins for use with the builder prior to building the engine:

**C++**
```cpp
for (size_t i = 0; i < nbPluginLibs; ++i)
{
    builder->getPluginRegistry().loadLibrary(pluginLibs[i]);
}
```

**Python**
```python
for plugin_lib in plugin_libs:
    builder.get_plugin_registry().load_library(plugin_lib)
```

Next, you will need to decide if the plugins should be included with the engine, or shipped externally. You can serialize the plugins with the plan as follows:

**C++**
```cpp
IBuilderConfig *config = builder->createBuilderConfig();
...
config->setPluginsToSerialize(pluginLibs, nbPluginLibs);
```

**Python**
```python
config = builder.create_builder_config()
...
config.plugins_to_serialize = plugin_libs
```

Alternatively, you can keep the plugins external to the engine. You will need to ship these libraries along with the engine when it is deployed, and load them explicitly in the runtime prior to deserializing the engine:

**C++**
```cpp
// In this example, getExternalPluginLibs() is a user-implemented method which retrieves the list of libraries to use with the engine
std::vector<std::string> pluginLibs = getExternalPluginLibs();
for (auto const &pluginLib : pluginLibs)
{
    runtime->getPluginRegistry().loadLibrary(pluginLib.c_str());
}
```

**Python**
```python
# In this example, get_external_plugin_libs() is a user-implemented method which retrieves the list of libraries to use with the engine
plugin_libs = get_external_plugin_libs()
for plugin_lib in plugin_libs:
    runtime.get_plugin_registry().load_library(plugin_lib)
```
Chapter 10. Working with Loops

NVIDIA TensorRT supports loop-like constructs, which can be useful for recurrent networks. TensorRT loops support scanning over input tensors, recurrent definitions of tensors, and both "scan outputs" and "last value" outputs.

10.1. Defining a Loop

A loop is defined by loop boundary layers.

- ITripLimitLayer specifies how many times that the loop iterates.
- IIteratorLayer enables a loop to iterate over a tensor.
- IRecurrenceLayer specifies a recurrent definition.
- ILoopOutputLayer specifies an output from the loop.

Each of the boundary layers inherits from class ILoopBoundaryLayer, which has a method getLoop() for getting its associated ILoop. The ILoop object identifies the loop. All loop boundary layers with the same ILoop belong to that loop.

Figure 12 depicts the structure of a loop and data flow at the boundary. Loop-invariant tensors can be used inside the loop directly, such as shown for FooLayer.
Figure 12. A TensorRT loop is set by loop boundary layers. Dataflow can leave the loop only by ILoopOutputLayer. The only back edges allowed are the second input to IRecurrenceLayer.

A loop can have multiple IIteratorLayer, IRecurrenceLayer, and ILoopOutputLayer, and at most two ITripLimitLayers as explained later. A loop with no ILoopOutputLayer has no output and is optimized by TensorRT.

Layers For Flow-Control Constructs describes the TensorRT layers that may be used in the loop interior.

Interior layers are free to use tensors defined inside or outside the loop. The interior can contain other loops (refer to Nested Loops) and other conditional constructs (refer to Conditionals Nesting).

To define a loop, first, create an ILoop object with the method INetworkDefinition::addLoop. Then add the boundary and interior layers. The rest of this section describes the features of the boundary layers, using loop to denote the ILoop* returned by INetworkDefinition::addLoop.

ITripLimitLayer supports both counted loops and while-loops.

- `loop->addTripLimit(t, TripLimit::kCOUNT)` creates an ITripLimitLayer whose input t is a 0D INT32 tensor that specifies the number of loop iterations.
- `loop->addTripLimit(t, TripLimit::kWHILE)` creates an ITripLimitLayer whose input t is a 0D Bool tensor that specifies whether an iteration should occur. Typically, t is either the output of an IRecurrenceLayer or a calculation based on said output.

A loop can have at most one of each kind of limit.

IIteratorLayer supports iterating forwards or backward over any axis.

- `loop->addIterator(t)` adds an IIteratorLayer that iterates over axis 0 of tensor t. For example, if the input is the matrix:
the output is the 1D tensor \{2, 3, 5\} on the first iteration and \{4, 6, 8\} for the second iteration. It is invalid to iterate beyond the tensor's bounds.

- \texttt{loop->addIterator(t, axis)} is similar, but the layer iterates over the given axis. For example, if \texttt{axis=1} and the input is a matrix, each iteration delivers a column of the matrix.

- \texttt{loop->addIterator(t, axis, reverse)} is similar, but the layer produces its output in reverse order if \texttt{reverse=true}.

\texttt{ILoopOutputLayer} supports three forms of loop output:

- \texttt{loop->addLoopOutput(t, LoopOutput::kLAST_VALUE)} outputs the last value of \texttt{t}, where \texttt{t} must be the output of a \texttt{IRecurrenceLayer}.

- \texttt{loop->addLoopOutput(t, LoopOutput::kCONCATENATE, axis)} outputs the concatenation of each iteration's input to \texttt{t}. For example, if the input is a 1D tensor, with value \{a, b, c\} on the first iteration and \{d, e, f\} on the second iteration, and \texttt{axis=0}, the output is the matrix:

  \[
  \begin{array}{ccc}
  a & b & c \\
  d & e & f \\
  \end{array}
  \]

  If \texttt{axis=1}, the output is:

  \[
  \begin{array}{cc}
  a & d \\
  b & e \\
  c & f \\
  \end{array}
  \]

- \texttt{loop->addLoopOutput(t, LoopOutput::kREVERSE, axis)} is similar, but reverses the order.

Both the \texttt{kCONCATENATE} and \texttt{kREVERSE} forms of \texttt{ILoopOutputLayer} require a second input, which is a 0D INT32 shape tensor specifying the length of the new output dimension. When the length is greater than the number of iterations, the extra elements contain arbitrary values. The second input, for example \texttt{u}, should be set using \texttt{ILoopOutputLayer::setInput(1, u)}.

Finally, there is \texttt{IRecurrenceLayer}. Its first input specifies the initial output value, and its second input specifies the next output value. The first input must come from outside the loop; the second input usually comes from inside the loop. For example, the TensorRT analog of this C++ fragment:

```c++
for (int32_t i = j; ...; i += k) ... could be created by these calls, where \texttt{j} and \texttt{k} are \texttt{ITensor*}.
```

```c++
ILoop* loop = n.addLoop();
IRecurrenceLayer* iRec = loop->addRecurrence();
ITensor* i = iRec->getOutput(0);
ITensor* iNext = addElementWise(*i, *k, ElementWiseOperation::kADD)->getOutput(0);
iRec->setInput(1, *iNext);
```

The second input to \texttt{IRecurrenceLayer} is the only case where TensorRT allows a back edge. If such inputs are removed, the remaining network must be acyclic.
10.2. Formal Semantics

TensorRT has applicative semantics, meaning there are no visible side effects other than engine inputs and outputs. Because there are no side effects, intuitions about loops from imperative languages do not always work. This section defines formal semantics for TensorRT's loop constructs.

The formal semantics is based on lazy sequences of tensors. Each iteration of a loop corresponds to an element in the sequence. The sequence for a tensor $x$ inside the loop is denoted $#x_0, x_1, x_2, \ldots#$. Elements of the sequence are evaluated lazily, meaning, as needed.

The output from $I\text{IteratorLayer}(X)$ is $#X[0], X[1], X[2], \ldots#$ where $X[i]$ denotes subscripting on the axis specified for the $I\text{IteratorLayer}$.

The output from $I\text{RecurrenceLayer}(X, Y)$ is $#X, Y_0, Y_1, Y_2, \ldots#$.

The input and output from an $I\text{LoopOutputLayer}$ depend on the kind of $\text{LoopOutput}$.

- **$k\text{LAST_VALUE}$**: Input is a single tensor $X$, and output is $X_n$ for an n-trip loop.
- **$k\text{CONCATENATE}$**: The first input is a tensor $X$, and the second input is a scalar shape tensor $Y$. The result is the concatenation of $X_0, X_1, X_2, \ldots, X_{n-1}$ with post padding, if necessary, to the length specified by $Y$. It is a runtime error if $Y < n$. $Y$ is a build time constant. Note the inverse relationship with $I\text{IteratorLayer}$. $I\text{IteratorLayer}$ maps a tensor to a sequence of subtensors; $I\text{LoopOutputLayer}$ with $k\text{CONCATENATE}$ maps a sequence of sub tensors to a tensor.
- **$k\text{REVERSE}$**: Similar to $k\text{CONCATENATE}$, but the output is in the reverse direction.

The value of $n$ in the definitions for the output of $I\text{LoopOutputLayer}$ is determined by the $I\text{TripLimitLayer}$ for the loop:

- For counted loops, it is the iteration count, meaning the input to the $I\text{TripLimitLayer}$.
- For while loops, it is the least $n$ such that $X_n$ is false, where $X$ is the sequence for the $I\text{TripLimitLayer}$’s input tensor.

The output from a non-loop layer is a sequence-wise application of the layer’s function. For example, for a two-input non-loop layer $F(X, Y) = #f(X_0, Y_0), f(X_1, Y_1), f(X_2, Y_2)\ldots#$, if a tensor comes from outside the loop, that is, a loop invariant, then the sequence for it is created by replicating the tensor.

10.3. Nested Loops

TensorRT infers the nesting of the loops from the data flow. For instance, if loop B uses values defined inside loop A, then B is considered to be nested inside of A.

TensorRT rejects networks where the loops are not cleanly nested, such as if loop A uses values defined in the interior of loop B and vice versa.
10.4. Limitations

A loop that refers to more than one dynamic dimension can take an unexpected amount of memory.

In a loop, memory is allocated as if all dynamic dimensions take on the maximum value of any of those dimensions. For example, if a loop refers to two tensors with dimensions $[4, x, y]$ and $[6, y]$, memory allocation for those tensors is as if their dimensions were $[4, \max(x, y), \max(x, y)]$ and $[6, \max(x, y)]$.

The input to a LoopOutputLayer with kLAST_VALUE must be the output from an IRecurrenceLayer.

The loop API supports only FP32 and FP16 precision.

10.5. Replacing IRNNv2Layer with Loops

IRNNv2Layer was deprecated in TensorRT 7.2.1 and will be removed in TensorRT 9.0. Use the loop API to synthesize a recurrent sub network. For an example, refer to sampleCharRNN, method SampleCharRNNLoop::addLSTMCell. You can express general recurrent networks instead of being limited to the prefabricated cells in IRNNLayer and IRNNv2Layer using the loop API.

Refer to sampleCharRNN for more information.
Chapter 11. Working with Conditionals

NVIDIA TensorRT supports conditional if-then-else flow control. TensorRT conditionals are used to implement conditional execution of network subgraphs.

11.1. Defining a Conditional

An if-conditional is defined by conditional boundary layers:

- **IConditionLayer** represents the predicate and specifies whether the conditional should execute the true-branch (then-branch) or the false-branch (else-branch).
- **IIfConditionalInputLayer** specifies an input to one of the two conditional branches.
- **IIfConditionalOutputLayer** specifies an output from a conditional.

Each of the boundary layers inherits from class **IIfConditionalBoundaryLayer**, which has a method **getConditional()** for getting its associated **IIfConditional**. The **IIfConditional** instance identifies the conditional. All conditional boundary layers with the same **IIfConditional** belong to that conditional.

A conditional must have exactly one instance of **IConditionLayer**, zero, or more instances of **IIfConditionalInputLayer**, and at least one instance of **IIfConditionalOutputLayer**.

**IIfConditional** implements an if-then-else flow-control construct that provides conditional-execution of a network subgraph based on a dynamic boolean input. It is defined by a boolean scalar predicate **condition**, and two branch subgraphs: a **trueSubgraph** which is executed when **condition** evaluates to **true**, and a **falseSubgraph** which is executed when **condition** evaluates to **false**:

```cpp
If condition is true then:
  output = trueSubgraph(trueInputs);
Else
  output = falseSubgraph(falseInputs);
Emit output
```

Both the true-branch and the false-branch must be defined, similar to the ternary operator in many programming languages.

To define an if-conditional, create an **IIfConditional** instance with the method **INetworkDefinition::addIfConditional**, then add the boundary and branch layers.

```cpp
IIfConditional* simpleIf = network->addIfConditional();
```
The `IIfConditional::setCondition` method takes a single argument: the condition tensor. This 0D boolean tensor (scalar) can be computed dynamically by earlier layers in the network. It is used to decide which of the branches to execute. An `IConditionLayer` has a single input (the condition) and no outputs since it is used internally by the conditional implementation.

```cpp
// Create a condition predicate that is also a network input.
auto cond = network->addInput("cond", DataType::kBOOL, Dims(0));
IConditionLayer* condition = simpleIf->setCondition(*cond);
```

TensorRT does not support a subgraph abstraction for implementing conditional branches and instead uses `IIfConditionalInputLayer` and `IIfConditionalOutputLayer` to define the boundaries of conditionals.

- An `IIfConditionalInputLayer` abstracts a single input to one or both of the branch subgraphs of an `IIfConditional`. The output of a specific `IIfConditionalInputLayer` can feed both branches.

```cpp
// Create an if-conditional input.
// x is some arbitrary Network tensor.
IIfConditionalInputLayer* inputX = simpleIf->addInput(*x);
```

Inputs to the then-branch and the else-branch do not have to be of the same type and shape. Each branch can independently include zero or more inputs.

- An `IIfConditionalOutputLayer` abstracts a single output of the if-conditional. It has two inputs: an output from the true-subgraph (input index 0) and an output from the false-subgraph (input index 1). The output of an `IIfConditionalOutputLayer` can be thought of as a placeholder for the final output that will be determined during runtime.

```cpp
// trueSubgraph and falseSubgraph represent network subgraphs
IIfConditionalOutputLayer* outputLayer = simpleIf->addOutput(
    *trueSubgraph->getOutput(0),
    *falseSubgraph->getOutput(0));
```

All outputs of an `IIfConditional` must be sourced at an `IIfConditionalOutputLayer` instance.

An if-conditional without outputs has no effect on the rest of the network, therefore, it is considered ill-formed. Each of the two branches (subgraphs) must also have at least one output. The output of an if-conditional can be marked as the output of the network, unless that if-conditional is nested inside another if-conditional or loop.

The diagram below provides a graphical representation of the abstract model of an if-conditional. The green rectangle represents the interior of the conditional, which is limited to the layer types listed in [Layers For Flow-Control Constructs](#).
11.2. Conditional Execution

Conditional execution of network layers is a network evaluation strategy in which branch-layers (the layers belonging to a conditional subgraph) are executed only if the values of the branch outputs are needed. In conditional-execution, either the true-branch or the false-branch is executed and allowed to change the network state.

In contrast, in predicated-execution, both the true-branch and the false-branch are executed and only one of these is allowed to change the network evaluation state, depending on the value of the condition predicate (that is, only the outputs of one of the subgraphs is fed into the following layers).

Conditional execution is sometimes called lazy evaluation, and predicated-execution is sometimes referred to as eager evaluation.

Instances of `IIfConditionalInputLayer` can be used to specify which layers are invoked eagerly and which are invoked lazily. This is done by tracing the network layers backwards,
starting with each of the conditional outputs. Layers that are data-dependent on the output of at least one `IIfConditionalInputLayer` are considered internal to the conditional and are therefore evaluated lazily. In the extreme case that no instances of `IIfConditionalInputLayer` are added to the conditional, all of the layers are executed eagerly, similarly to `ISelectLayer`.

The three diagrams below depict how the choice of `IIfConditionalInputLayer` placement controls execution scheduling.

**Figure 14. Controlling Conditional-Execution using `IIfConditionalInputLayer` Placement**

In diagram A, the true-branch is composed of three layers (T1, T2, T3). These layers execute lazily when the condition evaluates to `true`.

In diagram B, input-layer I1 is placed after layer T1, which moves T1 out of the true-branch. Layer T1 executes eagerly before evaluating the if-construct.

In diagram C, input-layer I1 is removed altogether, which moves T3 outside the conditional. T2’s input is reconfigured to create a legal network, and T2 also moves out of the true-branch. When the condition evaluates to `true`, the conditional does not compute anything since the outputs have already been eagerly computed (but it does copy the conditional relevant inputs to its outputs).

### 11.3. Nesting and Loops

Conditional branches may nest other conditionals and may also nest loops. Loops may nest conditionals. As in loop nesting, TensorRT infers the nesting of the conditionals and loops from the data flow. For example, if conditional B uses a value defined inside loop A, then B is considered to be nested inside of A.
There can be no cross-edges connecting layers in the true-branch to layers in the false-branch, and vice versa. In other words, the outputs of one branch cannot depend on layers in the other branch.

For example, refer to Conditional Examples for how nesting can be specified.

11.4. Limitations

The number of output tensors in both true/false subgraph branches must be the same. The type and shape of each output tensor from the branches must be the same.

Note that this is more constrained than the ONNX specification, which requires that the true/false subgraphs have the same number of outputs and use the same outputs data-types, but allows for different output shapes.

11.5. Conditional Examples

11.5.1. Simple If-Conditional

The following example shows how to implement a simple conditional that conditionally performs an arithmetic operation on two tensors.

```
Conditional

condition = true
If condition is true:
  output = x + y
Else:
  output = x - y

Example

ITensor* addCondition(INetworkDefinition& n, bool predicate)
{
    // The condition value is a constant int32 input that is cast to boolean because TensorRT doesn't support boolean constant layers.
    static const Dims scalarDims = Dims({0, {}});
    static float constexpr zero(0);
    static float constexpr one(1);
    float* const val = predicate ? &one : &zero;
    ITensor* cond = n.addConstant(scalarDims, DataType::kINT32, val, 1)->getOutput(0);
    auto* cast = n.addIdentity(cond);
    cast->setOutputType(0, DataType::kBOOL);
    cast->getOutput(0)->setType(DataType::kBOOL);
    return cast->getOutput(0);
}
```

IBuilder* builder = createInferBuilder(gLogger);
In this section, we will explore how to work with conditionals in NVIDIA TensorRT.

11.5.2. Exporting from PyTorch

The following example shows how to export scripted PyTorch code to ONNX. The code in function `sum_even` performs an if-conditional nested in a loop.

```python
import torch.onnx
import torch
import tensorrt as trt
import numpy as np

TRT_LOGGER = trt.Logger(trt.Logger.WARNING)
EXPLICIT_BATCH = 1 << (int)(trt.NetworkDefinitionCreationFlag.EXPLICIT_BATCH)

@torch.jit.script
def sum_even(items):
    s = torch.zeros(1, dtype=torch.float)
    for c in items:
        if c % 2 == 0:
            s += c
    return s

class ExampleModel(torch.nn.Module):
    def __init__(self):
        super().__init__()
    def forward(self, items):
        return sum_even(items)

def build_engine(model_file):
    builder = trt.Builder(TRT_LOGGER)
    network = builder.create_network(EXPLICIT_BATCH)
    config = builder.create_builder_config()
    parser = trt.OnnxParser(network, TRT_LOGGER)
    with open(model_file, 'rb') as model:
        assert parser.parse(model.read())
    return builder.build_engine(network, config)

def export_to_onnx():
    items = torch.zeros(4, dtype=torch.float)
    example = ExampleModel()
    torch.onnx.export(example, (items), "example.onnx", verbose=False, opset_version=13,
                      enable_onnx_checker=False, do_constant_folding=True)

export_to_onnx()
build_engine("example.onnx")
```
Chapter 12. Working with DLA

NVIDIA DLA (Deep Learning Accelerator) is a fixed-function accelerator engine targeted for deep learning operations. DLA is designed to do full hardware acceleration of convolutional neural networks. DLA supports various layers such as convolution, deconvolution, fully connected, activation, pooling, batch normalization, and so on. DLA does not support Explicit Quantization. For more information about DLA support in TensorRT layers, refer to DLA Supported Layers and Restrictions.

DLA is useful for offloading CNN processing from the iGPU, and is significantly more power-efficient for these workloads. In addition, it can provide an independent execution pipeline in cases where redundancy is important, for example in mission-critical or safety applications.

For more information about DLA, refer to the DLA developer page and the DLA tutorial Getting started with the Deep Learning Accelerator on NVIDIA Jetson Orin.

When building a model for DLA, the TensorRT builder parses the network and calls the DLA compiler to compile the network into a DLA loadable. Refer to Using trtexec to see how to build and run networks on DLA.
12.1. Building and Launching the Loadable

There are several different ways to build and launch a DLA loadable, either embedded in a TensorRT engine or in standalone form.

For generating a standalone DLA loadable to be used outside TensorRT, refer to DLA Standalone Mode.
12.1.1. Using trtexec

To allow trtexec to use the DLA, you can use the --useDLACore flag. For example, to run the ResNet-50 network on DLA core 0 in FP16 mode, with GPU Fallback Mode for unsupported layers, issue:

```
./trtexec --onnx=data/resnet50/ResNet50.onnx --useDLACore=0 --fp16 --allowGPUFallback
```

The trtexec tool has additional arguments to run networks on DLA. For more information, refer to Command-Line Programs.

12.1.2. Using the TensorRT API

You can use the TensorRT API to build and run inference with DLA and to enable DLA at layer level. The relevant APIs and samples are provided in the following sections.

12.1.2.1. Running on DLA during TensorRT Inference

The TensorRT builder can be configured to enable inference on DLA. DLA support is currently limited to networks running in FP16 and INT8 mode. The DeviceType enumeration is used to specify the device that the network or layer executes on. The following API functions in the IBuilderConfig class can be used to configure the network to use DLA:

- `setDeviceType(ILayer* layer, DeviceType deviceType)`
  This function can be used to set the `deviceType` that the layer must execute on.
- `getDeviceType(const ILayer* layer)`
  This function can be used to return the `deviceType` that this layer executes on. If the layer is executing on the GPU, this returns `DeviceType::kGPU`.
- `canRunOnDLA(const ILayer* layer)`
  This function can be used to check if a layer can run on DLA.
- `setDefaultDeviceType(DeviceType deviceType)`
  This function sets the default `deviceType` to be used by the builder. It ensures that all the layers that can run on DLA runs on DLA unless `setDeviceType` is used to override the `deviceType` for a layer.
- `getDefaultDeviceType()`
  This function returns the default `deviceType` which was set by `setDefaultDeviceType`.
- `isDeviceTypeSet(const ILayer* layer)`
  This function checks whether the `deviceType` has been explicitly set for this layer.
- `resetDeviceType(ILayer* layer)`
  This function resets the `deviceType` for this layer. The value is reset to the `deviceType` that is specified by `setDefaultDeviceType` or `DeviceType::kGPU` if none is specified.
- `allowGPUFallback(bool setFallbackMode)`
  This function notifies the builder to use GPU if a layer that was supposed to run on DLA cannot run on DLA. For more information, refer to GPU Fallback Mode.
- `reset()`
  This function can be used to reset the IBuilderConfig state, which sets the `deviceType` for all layers to be `DeviceType::kGPU`. After reset, the builder can be reused to build another network with a different DLA config.
The following API functions in `IBuilder` class can be used to help configure the network for using the DLA:

```c++
getMaxDLABatchSize()
```
This function returns the maximum batch size DLA can support.

**Note:** For any tensor, the total volume of index dimensions combined with the requested batch size must not exceed the value returned by this function.

```c++
getNbDLACores()
```
This function returns the number of DLA cores available to the user.

If the builder is not accessible, such as in the case where a plan file is being loaded online in an inference application, then the DLA to be used can be specified differently by using DLA extensions to the `IRuntime`. The following API functions in the `IRuntime` class can be used to configure the network to use DLA:

```c++
getNbDLACores()
```
This function returns the number of DLA cores that are accessible to the user.

```c++
setDLACore(int dlaCore)
```
The DLA core to execute on. Where `dlaCore` is a value between 0 and `getNbDLACores() - 1`. The default value is 0.

```c++
getDLACore()
```
The DLA core that the runtime execution is assigned to. The default value is 0.

### 12.1.2.2. Example: Run Samples with DLA

This section provides details on how to run a TensorRT sample with DLA enabled.

Create the builder:

```c++
auto builder = SampleUniquePtr<nvinfer1::IBuilder>(nvinfer1::createInferBuilder(gLogger));
if (!builder) return false;
builder->setMaxBatchSize(batchSize);
config->setMaxWorkspaceSize(16_MB);
```

Then, enable GPUFallback mode:

```c++
config->setFlag(BuilderFlag::kGPU_FALLBACK);
config->setFlag(BuilderFlag::kFP16); or config->setFlag(BuilderFlag::kINT8);
```

Enable execution on DLA, where `dlaCore` specifies the DLA core to execute on:

```c++
config->setDefaultDeviceType(DeviceType::kDLA);
config->setDLACore(dlaCore);
```

With these additional changes, sampleMNIST is ready to execute on DLA. To run samples with DLA Core 1, append `--useDLACore=0` to the sample command.

### 12.1.2.3. Example: Enable DLA Mode for a Layer during Network Creation

In this example, let us create a simple network with Input, Convolution, and Output.

1. Create the builder, builder configuration, and the network:

   ```c++
   IBuilder* builder = createInferBuilder(gLogger);
   IBuilderConfig* config = builder.createBuilderConfig();
   INetworkDefinition* network = builder->createNetworkV2(0U);
   ```

2. Add the Input layer to the network, with the input dimensions.
3. Add the Convolution layer with hidden layer input nodes, strides, and weights for filter and bias.

```cpp
auto data = network->addInput(INPUT_BLOB_NAME, dt, Dims3{1, INPUT_H, INPUT_W});

auto conv1 = network->addConvolution(*data->getOutput(0), 20, DimsHW{5, 5},
    weightMap["conv1filter"], weightMap["conv1bias"]);
conv1->setStride(DimsHW{1, 1});
```

4. Set the convolution layer to run on DLA:

```cpp
if(canRunOnDLA(conv1))
{
    config->setFlag(BuilderFlag::kFP16); or config->setFlag(BuilderFlag::kINT8);
    builder->setDeviceType(conv1, DeviceType::kDLA);
}
```

5. Mark the output:

```cpp
network->markOutput(*conv1->getOutput(0));
```

6. Set the DLA core to execute on:

```cpp
config->setDLACore(0)
```

### 12.1.3. Using the cuDLA API

cuDLA is an extension of the CUDA programming model that integrates DLA runtime software with CUDA. This integration makes it possible to launch DLA loadables using CUDA programming constructs such as streams and graphs.

Managing shared buffers as well as synchronizing the tasks between GPU and DLA is transparently handled by cuDLA. Refer to the NVIDIA cuDLA documentation on how the cuDLA APIs can be used for these use cases while writing a cuDLA application.

Refer to the DLA Standalone Mode section for more information on how to use TensorRT to build a standalone DLA loadable usable with cuDLA.

### 12.2. DLA Supported Layers and Restrictions

This section lists the layers supported by DLA along with the constraints associated with each layer.

#### 12.2.1. General Restrictions

The following restrictions apply to all layers while running on DLA:

- The maximum supported batch size is 4096.
- DLA does not support dynamic dimensions. Thus, for wildcard dimensions, the min, max, and opt values of the profile must be equal.
- The runtime dimension (especially the batch size) must be the same as the dimension used for building.
TensorRT may split a network into multiple DLA loadables if any intermediate layers cannot run on DLA and GPU Fallback is enabled. Otherwise, TensorRT can emit an error and fallback. For more information, refer to GPU Fallback Mode.

At most, 16 DLA loadables can be loaded concurrently, per core, due to hardware and software memory limitations.

**Note:** Batch size for DLA is the product of all index dimensions except the CHW dimensions. For example, if input dimensions are NPQRS, the effective batch size is N*P.

### 12.2.2. Layer Support and Restrictions

The following list provides layer support and restrictions to the specified layers while running on DLA:

#### Convolution and Fully Connected layers

- Only two spatial dimension operations are supported.
- Both FP16 and INT8 are supported.
- Each dimension of the kernel size must be in the range $[1, 32]$.
- Padding must be in the range $[0, 31]$.
- Dimensions of padding must be less than the corresponding kernel dimension.
- Dimensions of stride must be in the range $[1, 8]$.
- Number of output maps must be in the range $[1, 8192]$.
- Number of groups must be in the range $[1, 8192]$ for operations using the formats TensorFormat::kLINEAR, TensorFormat::kCHW16, and TensorFormat::kCHW32.
- Number of groups must be in the range $[1, 4]$ for operations using the formats TensorFormat::kDLA_HWC4.
- Dilated convolution must be in the range $[1, 32]$.
- Operations are not supported if the CBUF size requirement $wtBanksForOneKernel + minDataBanks$ exceeds the $numConvBufBankAllotted$ limitation 16, where CBUF is the internal convolution cache that stores input weights and activation before operating on them, $wtBanksForOneKernel$ is the minimum banks for one kernel to store the minimum weight/kernel elements needed for convolution, and $minDataBanks$ is the minimum banks to store the minimum activation data needed for convolution. When a convolution layer fails validation due to CBUF constraints, details are displayed in the logging output.

#### Deconvolution layer

- Only two spatial dimensions are supported.
- Both FP16 and INT8 are supported.
- Dimensions of the kernel must be in the range $[1, 32]$, in addition to $1x[64, 96, 128]$ and $[64, 96, 128]x1$. 

---

**Working with DLA**

NVIDIA TensorRT
- TensorRT has disabled deconvolution square kernels and strides in the range \([23 - 32]\) on DLA as they significantly slow down compilation.
- Padding must be 0
- Grouped deconvolution must be 1.
- Dilated deconvolutions must be 1.
- Number of input channels must be in the range \([1, 8192]\).
- Number of output channels must be in the range \([1, 8192]\).

Pooling layer
- Only two spatial dimension operations are supported.
- Both FP16 and INT8 are supported.
- Operations supported: kMAX, kAVERAGE.
- Dimensions of the window must be in the range \([1, 8]\).
- Dimensions of padding must be in the range \([0, 7]\).
- Dimensions of stride must be in the range \([1, 16]\).
- With INT8 mode, input and output tensor scales must be the same.

Activation layer
- Only two spatial dimension operations are supported.
- Both FP16 and INT8 are supported.
- Functions supported: ReLU, Sigmoid, TanH, Clipped ReLU, and Leaky ReLU.
  - Negative slope is not supported for ReLU.
  - Clipped ReLU only supports values in the range \([1, 127]\).
  - TanH, Sigmoid INT8 support is supported by auto-upgrading to FP16.

Parametric ReLU layer
- Slope input must be a build time constant and have the same rank as the input tensor.

ElementWise layer
- Only two spatial dimension operations are supported.
- Both FP16 and INT8 are supported.
- Operations supported: Sum, Sub, Product, Max, Min, and Equal (described separately).

Note: On Xavier, TensorRT concatenates a DLA Scale layer and a DLA ElementWise layer with the operation Sum to support the Sub operation, which is not supported by a single Xavier DLA ElementWise layer.
Equal operation

- Only supports INT8 as layer and input precisions.
  - You must enable INT8 precision when building the engine.
- DLA requires that the equal operation output be FP16 or INT8 type. Thus, the equal layer must be immediately followed by a Cast operation (IIdentityLayer) to FP16 or INT8 and should have no direct consumers other than this Cast operation.
- If you want to have a boolean tensor output from the equal layer while having it run on DLA, add another cast operation to cast the FP16 or INT8 output back to BOOL on the GPU.
- For both the ElementWise equal layer and the subsequent IIdentityLayer mentioned above, explicitly set your device types to DLA and their precisions to INT8. Otherwise, these layers will run on the GPU.
- Even with GPU fallback allowed, you should expect failures in engine construction in some cases, for example when DLA loadable compilation fails. If this is the case, unset the device types and/or precisions of both the ElementWise equal layer and IIdentityLayer to have both offloaded to GPU.

Scale layer

- Only two spatial dimension operations are supported.
- Both FP16 and INT8 are supported.
- Mode supported: Uniform, Per-Channel, and ElementWise.
- Only scale and shift operations are supported.

LRN (Local Response Normalization) layer

- Allowed window sizes are 3, 5, 7, or 9.
- Normalization region supported is ACROSS_CHANNELS.
- LRN INT8 is supported by auto-upgrading to FP16.

Concatenation layer

- DLA supports concatenation only along the channel axis.
- Concat must have at least two inputs.
- All the inputs must have the same spatial dimensions.
- With INT8 mode, the dynamic range of all the inputs must be the same.
- With INT8 mode, the dynamic range of output must be equal to each of the inputs.

Resize layer

- The number of scales must be exactly 4.
The first two elements in scales must be exactly 1 (for unchanged batch and channel dimensions).

The last two elements in scales, representing the scale values along height and width dimensions, respectively, must be integer values in the range of \([1, 32]\) in nearest-neighbor mode and \([1, 4]\) in bilinear mode.

### Unary layer

- Only the ABS operation is supported.

### Slice layer

- Only supports FP16 precision.
- Supports batch sizes up to general DLA maximum.
- All input non-batch dimensions must be in the range \([1, 8192]\).
- Only supports 4-D inputs and slicing at CHW dimensions.
- Only supports static slicing, so slice parameters have to be provided statically either using TensorRT ISliceLayer setter APIs or as constant input tensors.

### SoftMax layer

- Only supported on NVIDIA Orin™, not Xavier™.
- All input non-batch dimensions must be in the range \([1, 8192]\).
- Only supports FP16 precision.
- Internally, there are two modes, and the mode is selected based on the given input tensor shape.
  - The accurate mode is triggered when all non-batch, non-axis dimensions are 1.
  - The optimized mode allows the non-batch, non-axis dimensions to be greater than 1 but restricts the axis dimension to 1024 and involves an approximation that may cause a small error in the output. The magnitude of the error increases as the size of the axis dimension approaches 1024.

### Shuffle layer

- Only supports 4-D input tensors.
- All input non-batch dimensions must be in the range \([1, 8192]\).
- Note that DLA decomposes the layer into standalone transpose and reshape operations. This means that the above restrictions apply individually to each of the decomposed operations.
- Batch dimensions cannot be involved in either reshapes or transposes.
12.2.3. Inference on NVIDIA Orin

Due to the difference in hardware specifications between NVIDIA Orin and Xavier DLA, an increase up to 2x in latency may be observed for FP16 convolution operations on NVIDIA Orin.

On NVIDIA Orin, DLA stores weights for non-convolution operations (FP16 and INT8) inside a loadable as FP19 values (which use 4 byte containers). The channel dimensions are padded to multiples of either 16 (FP16) or 32 (INT8) for those FP19 values. Especially in the case of large per-element Scale, Add, or Sub operations, this can inflate the size of the DLA loadable, inflating the engine containing such a loadable. Graph optimization may unintentionally trigger this behavior by changing the type of a layer, for example, when an ElementWise multiplication layer with a constant layer as weights is fused into a scale layer.

12.3. GPU Fallback Mode

The GPUFallbackMode sets the builder to use GPU if a layer that was marked to run on DLA could not run on DLA. A layer cannot run on DLA due to the following reasons:

1. The layer operation is not supported on DLA.
2. The parameters specified are out of the supported range for DLA.
3. The given batch size exceeds the maximum permissible DLA batch size. For more information, refer to DLA Supported Layers and Restrictions.
4. A combination of layers in the network causes the internal state to exceed what the DLA is capable of supporting.
5. There are no DLA engines available on the platform.

When GPU fallback is disabled, an error is emitted if a layer could not be run on DLA.

12.4. I/O Formats on DLA

DLA supports formats that are unique to the device and have constraints on their layout due to vector width byte requirements.

For DLA input tensors, kDLA_LINEAR(FP16, INT8), kDLA_HWC4(FP16, INT8), kCHW16(FP16), and kCHW32(INT8) are supported. For DLA output tensors, only kDLA_LINEAR(FP16, INT8), kCHW16(FP16), and kCHW32(INT8) are supported. For kCHW16 and kCHW32 formats, if C is not an integer multiple, then it must be padded to the next 32-byte boundary.

For kDLA_LINEAR format, the stride along the W dimension must be padded up to 64 bytes. The memory format is equivalent to a C array with dimensions [N][C][H][roundUp(W, 64/elementSize)] where elementSize is 2 for FP16 and 1 for Int8, with the tensor coordinates (n, c, h, w) mapping to array subscript [n][c][h][w].

For kDLA_HWC4 format, the stride along the W dimension must be a multiple of 32 bytes on Xavier and 64 bytes on NVIDIA Orin.
- When \( C = 1 \), TensorRT maps the format to the native grayscale image format.
- When \( C = 3 \) or \( C = 4 \), it maps to the native color image format. If \( C = 3 \), the stride for stepping along the \( w \) axis must be padded to 4 in elements.

In this case, the padded channel is located at the 4th-index. Ideally, the padding value does not matter because the 4th channel in the weights is padded to zero by the DLA compiler; however, it is safe for the application to allocate a zero-filled buffer of four channels and populate three valid channels.

- When \( C \) is \{1, 3, 4\}, then padded \( C' \) is \{1, 4, 4\} respectively, the memory layout is equivalent to a \( C \) array with dimensions \([N][H][\text{roundUp}(W, 32/C'/\text{elementSize})][C']\) where \( \text{elementSize} \) is 2 for FP16 and 1 for Int8. The tensor coordinates \((n, c, h, w)\) mapping to array subscript \([n][h][w][c]\), \( \text{roundUp} \) calculates the smallest multiple of \( 64/\text{elementSize} \) greater than or equal to \( W \).

When using \texttt{kDLA_HWC4} as DLA input format, it has the following requirements:

- \( C \) must be 1, 3, or 4
- The first layer must be convolution.
- The convolution parameters must meet DLA requirements. Refer to DLA Supported Layers and Restrictions for more information.

When GPU fallback is enabled, TensorRT may insert reformatting layers to meet the DLA requirements. Otherwise, the input and output formats must be compatible with DLA. In all cases, the strides that TensorRT expects data to be formatted with can be obtained by querying \texttt{IExecutionContext::getStrides}.

### 12.5. DLA Standalone Mode

If you need to run inference outside of TensorRT, you can use \texttt{EngineCapability::kDLA_STANDALONE} to generate a DLA loadable instead of a TensorRT engine. This loadable can then be used with an API like Using the cuDLA API.

#### 12.5.1. Building A DLA Loadable Using C++

1. Set the default device type and engine capability to DLA standalone mode.
   
   ```cpp
   builderConfig->setDefaultDeviceType(DeviceType::kDLA);
   builderConfig->setEngineCapability(EngineCapability::kDLA_STANDALONE);
   ```

2. Specify FP16, INT8, or both. For example:
   
   ```cpp
   builderConfig->setFlag(BuilderFlag::kFP16);
   ```

3. DLA standalone mode disallows reformatting, therefore \texttt{BuilderFlag::kDIRECT_IO} needs to be set.
   
   ```cpp
   builderConfig->setFlag(BuilderFlag::kDIRECT_IO);
   ```

4. You must set the allowed formats for I/O tensors to one or more of those supported by DLA. See the documentation for the TensorFormat enum for details.

5. Finally, build as normal
12.5.1.1. Using `trtexec` To Generate A DLA Loadable

The `trtexec` tool can generate a DLA loadable instead of a TensorRT engine. Specifying both `--useDLACore` and `--safe` parameters sets the builder capability to `EngineCapability::kDLA_STANDALONE`. Additionally, specifying `--inputIOFormats` and `--outputIOFormats` restricts I/O data type and memory layout. The DLA loadable is saved into a file by specifying `--saveEngine` parameter.

For example, to generate an FP16 DLA loadable for an ONNX model using `trtexec`, issue:

```
./trtexec --onnx=model.onnx --saveEngine=model_loadable.bin --useDLACore=0 --fp16 --inputIOFormats=fp16:chw16 --outputIOFormats=fp16:chw16 --skipInference --safe
```

12.6. Customizing DLA Memory Pools

You can customize the size of the memory pools allocated to each DLA subnetwork in a network using the `IBuilderConfig::setMemoryPoolLimit` C++ API or the `IBuilderConfig.set_memory_pool_limit` Python API. There are three types of DLA memory pools (refer to the `MemoryPoolType` enum for details):

**Managed SRAM**
- Behaves like a cache and larger values may improve performance.
- If no managed SRAM is available, DLA can still run by falling back to local DRAM.
- On Orin, each DLA core has 1 MiB of dedicated SRAM. On Xavier, 4 MiB of SRAM is shared across multiple cores including the 2 DLA cores.

**Local DRAM**
- Used to store intermediate tensors in the DLA subnetwork. Larger values may allow larger subnetworks to be offloaded to DLA.

**Global DRAM**
- Used to store weights in the DLA subnetwork. Larger values may allow larger subnetworks to be offloaded to DLA.

The amount of memory required for each subnetwork may be less than the pool size, in which case the smaller amount will be allocated. The pool size serves only as an upper bound.

Note that all DLA memory pools require sizes that are powers of 2, with a minimum of 4 KiB. Violating this requirement results in a DLA loadable compilation failure.

In multi-subnetwork situations, it is important to keep in mind that the pool sizes apply per DLA subnetwork, not for the whole network, so it is necessary to be aware of the total amount of resources being consumed. In particular, your network can consume at most twice the managed SRAM as the pool size in aggregate.

For NVIDIA Orin, the default managed SRAM pool size is set to 0.5 MiB whereas Xavier has 1 MiB as the default. This is because Orin has a strict per-core limit, whereas Xavier has some flexibility. This Orin default guarantees in all situations that the aggregate managed SRAM consumption of your engine stays below the hardware limit, but if your engine
has only a single DLA subnetwork, this would mean your engine only consumes half the hardware limit so you may see a perf boost by increasing the pool size to 1 MiB.

### 12.6.1. Determining DLA Memory Pool Usage

Upon successfully compiling loadables from the given network, the builder reports the number of subnetwork candidates that were successfully compiled into loadables, as well as the total amount of memory used per pool by those loadables. For each subnetwork candidate that failed due to insufficient memory, a message will be emitted to point out which memory pool was insufficient. In the verbose log, the builder also reports the memory pool requirements of each loadable.

### 12.7. Sparsity on DLA

DLA on the NVIDIA Orin platform supports structured sparsity (SS) that offers the opportunity to minimize latency and maximize throughput in production.

#### 12.7.1. Structured Sparsity

Structured sparsity (SS) accelerates a 2:4 sparsity pattern along the C dimension. In each contiguous block of four values, two values must be zero along C. Generally, SS provides the most benefit for INT8 convolutions that are math-bound, have a channel dimension that is a multiple of 128.

Structured Sparsity has several requirements and limitations.

**Requirements**

- Only available for INT8 convolution for formats other than NHWC.
- Channel size must be larger than 64.

**Limitations**

- Only convolutions whose quantized INT8 weights are at most 256K can benefit from SS—in practice, the limitation may be more restrictive.
- Only convolutions with \( K \% 64 \in \{0, 1, 2, 4, 8, 16, 32\} \), where \( K \) is the number of kernels (corresponding to the number of output channels), can benefit from SS in this release.
Chapter 13. Performance Best Practices

13.1. Measuring Performance

Before starting any optimization effort with TensorRT, it is essential to determine what should be measured. Without measurements, it is impossible to make reliable progress or measure whether success has been achieved.

Latency

A performance measurement for network inference is how much time elapses from an input being presented to the network until an output is available. This is the latency of the network for a single inference. Lower latencies are better. In some applications, low latency is a critical safety requirement. In other applications, latency is directly visible to users as a quality-of-service issue. For bulk processing, latency may not be important at all.

Throughput

Another performance measurement is how many inferences can be completed in a fixed unit of time. This is the throughput of the network. Higher throughput is better. Higher throughputs indicate a more efficient utilization of fixed compute resources. For bulk processing, the total time taken will be determined by the throughput of the network.

Another way of looking at latency and throughput is to fix the maximum latency and measure throughput at that latency. A quality-of-service measurement like this can be a reasonable compromise between the user experience and system efficiency.

Before measuring latency and throughput, you must choose the exact points at which to start and stop timing. Depending on the network and application, it might make sense to choose different points.

In many applications, there is a processing pipeline, and the overall system performance can be measured by the latency and throughput of the entire processing pipeline. Because the pre- and post-processing steps depend so strongly on the particular
application, this section considers the latency and throughput of the network inference only.

13.1.1. Wall-clock Timing

Wall-clock time (the elapsed time between the start of a computation and its end) can be useful for measuring the overall throughput and latency of the application, and for placing inference times in context within a larger system. C++11 provides high precision timers in the `<chrono>` standard library. For example, `std::chrono::system_clock` represents system-wide wall-clock time, and `std::chrono::high_resolution_clock` measures time in the highest precision available.

The following example code snippet shows measuring network inference host time:

**C++**
```cpp
#include <chrono>

auto startTime = std::chrono::high_resolution_clock::now();
context->enqueueV3(stream);
cudaStreamSynchronize(stream);
auto endTime = std::chrono::high_resolution_clock::now();
float totalTime = std::chrono::duration<float, std::milli>(endTime - startTime).count();
```

**Python**
```python
import time
from cuda import cudart
err, stream = cudart.cudaStreamCreate()
start_time = time.time()
context.execute_async_v3(stream)
cudart.cudaStreamSynchronize(stream)
total_time = time.time() - start_time
```

If there is only one inference happening on the device at one time, then this can be a simple way of profiling the time various operations take. Inference is typically asynchronous, so ensure you add an explicit CUDA stream or device synchronization to wait for results to become available.

13.1.2. CUDA Events

One problem with timing on the host exclusively is that it requires host/device synchronization. Optimized applications may have many inferences running in parallel on the device with overlapping data movement. In addition, the synchronization itself adds some amount of noise to timing measurements.

To help with these issues, CUDA provides an Event API. This API allows you to place events into CUDA streams that will be time-stamped by the GPU as they are encountered. Differences in timestamps can then tell you how long different operations took.

The following example code snippet shows computing the time between two CUDA events:

**C++**
```cpp
cudaEvent_t start, end;
cudaEventCreate(&start);
cudaEventCreate(&end);

cudaEventRecord(start, stream);
context->enqueueV3stream();
cudaEventRecord(end, stream);
```
cudaEventSynchronize(end);
float totalTime;
cudaEventElapsedTime(&totalTime, start, end);

Python
from cuda import cudart
err, stream = cudart.cudaStreamCreate()
err, start = cudart.cudaEventCreate()
err, end = cudart.cudaEventCreate()
cudart.cudaEventRecord(start, stream)
context.execute_async_v3(stream)
cudart.cudaEventRecord(end, stream)
cudart.cudaEventSynchronize(end)
err, total_time = cudart.cudaEventElapsedTime(start, end)

13.1.3. Built-In TensorRT Profiling
Digging deeper into the performance of inference requires more fine-grained timing measurements within the optimized network.

TensorRT has a Profiler (C++, Python) interface, which you can implement in order to have TensorRT pass profiling information to your application. When called, the network will run in a profiling mode. After finishing inference, the profiler object of your class is called to report the timing for each layer in the network. These timings can be used to locate bottlenecks, compare different versions of a serialized engine, and debug performance issues.

The profiling information can be collected from a regular inference enqueueV3() launch or a CUDA graph launch. Refer to IExecutionContext::setProfiler() and IExecutionContext::reportToProfiler() (C++, Python) for more information.

Layers inside a loop compile into a single monolithic layer, therefore, separate timings for those layers are not available. Also, some subgraphs (especially with Transformer-like networks) are handled by a next-generation graph optimizer that is not yet integrated with the Profiler APIs. For those networks, use CUDA Profiling Tools to profile per-layer performance.

An example showing how to use the IProfiler interface is provided in the common sample code (common.h).

You can also use trtexec to profile a network with TensorRT given an input network or plan file. Refer to the trtexec section for details.

13.1.4. CUDA Profiling Tools
The recommended CUDA profiler is NVIDIA Nsight™ Systems. Some CUDA developers may be more familiar with nvprof and nvvp, however, these are being deprecated. In any case, these profilers can be used on any CUDA program to report timing information about the kernels launched during execution, data movement between host and device, and CUDA API calls used.

Nsight Systems can be configured in various ways to report timing information for only a portion of the execution of the program or to also report traditional CPU sampling profile information together with GPU information.
The basic usage of Nsight Systems is to first run the command `nsys profile -o <OUTPUT> <INFEERENCE_COMMAND>`, then, open the generated `<OUTPUT>_.nsys-rep` file in the Nsight Systems GUI to visualize the captured profiling results.

**Profile Only the Inference Phase**

When profiling a TensorRT application, you should enable profiling only after the engine has been built. During the build phase, all possible tactics are tried and timed. Profiling this portion of the execution will not show any meaningful performance measurements and will include all possible kernels, not the ones actually selected for inference. One way to limit the scope of profiling is to:

- **First phase:** Structure the application to build and then serialize the engines in one phase.
- **Second phase:** Load the serialized engines and run inference in a second phase and profile this second phase only.

If the application cannot serialize the engines, or if the application must run through the two phases consecutively, you can also add `cudaProfilerStart()/cudaProfilerStop()` CUDA APIs around the second phase and add `-c cudaProfilerApi` flag to Nsight Systems command to profile only the part between `cudaProfilerStart()` and `cudaProfilerStop()`.

**Understand Nsight Systems Timeline View**

In the Nsight Systems Timeline View, the GPU activities are shown at the rows under **CUDA HW** and the CPU activities are shown at the rows under **Threads**. By default, the rows under **CUDA HW** are collapsed, therefore, you must click on it to expand the rows.

In a typical inference workflow, the application calls the `context->enqueueV3()` or `context->executeV3()` APIs to enqueue the jobs and then synchronize on the stream to wait until the GPU completes the jobs. It may appear as if the system is doing nothing for a while in the `cudaStreamSynchronize()` call if you only look at the CPU activities. In fact, the GPU may be busy executing the enqueued jobs while the CPU is waiting. The following figure shows an example timeline of the inference of a query.

The `trtexec` tool uses a slightly more complicated approach to enqueue the jobs by enqueuing the next query while GPU is still executing the jobs from the previous query. Refer to the `trtexec` section for more information.

The following image shows a typical view of the normal inference workloads in the Nsight Systems timeline view, showing CPU and GPU activities on different rows.
Use the NVTX Tracing in Nsight Systems

Enabling NVIDIA Tools Extension SDK (NVTX) tracing allows Nsight Compute and Nsight Systems to collect data generated by TensorRT applications. NVTX is a C-based API for marking events and ranges in your applications.

Decoding the kernel names back to layers in the original network can be complicated. Because of this, TensorRT uses NVTX to mark a range for each layer, which then allows the CUDA profilers to correlate each layer with the kernels called to implement it. In TensorRT, NVTX helps to correlate the runtime engine layer execution with CUDA kernel calls. Nsight Systems supports collecting and visualizing these events and ranges on the timeline. Nsight Compute also supports collecting and displaying the state of all active NVTX domains and ranges in a given thread when the application is suspended.

In TensorRT, each layer may launch one or more kernels to perform its operations. The exact kernels launched depend on the optimized network and the hardware present. Depending on the choices of the builder, there may be multiple additional operations that reorder data interspersed with layer computations; these reformat operations may be implemented as either device-to-device memory copies or as custom kernels.

For example, the following screenshots are from Nsight Systems.
Figure 17. The Layer Execution and the Kernel Being Launched on the CPU Side

The kernels actually run on the GPU, in other words, the following image shows the correlation between the layer execution and kernel launch on the CPU side and their execution on the GPU side.

Figure 18. The Kernels Run on the GPU
Control the Level of Details in NVTX Tracing

By default, TensorRT only shows layer names in the NVTX markers, while users can control the level of details by setting the ProfilingVerbosity in the IBuilderConfig when the engine is built. For example, to disable NVTX tracing, set the ProfilingVerbosity to kNONE:

C++
```cpp
builderConfig->setProfilingVerbosity(ProfilingVerbosity::kNONE);
```

Python
```python
builder_config.profiling_verbosity = trt.ProfilingVerbosity.NONE
```

On the other hand, you can choose to allow TensorRT to print more detailed layer information in the NVTX markers, including input and output dimensions, operations, parameters, tactic numbers, and so on, by setting the ProfilingVerbosity to kDETAILED:

C++
```cpp
builderConfig->setProfilingVerbosity(ProfilingVerbosity::kDETAILED);
```

Python
```python
builder_config.profiling_verbosity = trt.ProfilingVerbosity.DETAILED
```

Run Nsight Systems with trtexec

Below is an example of the commands to gather Nsight Systems profiles using trtexec tool:

```bash
trtexec --onnx=foo.onnx --profilingVerbosity=detailed --saveEngine=foo.plan
nsys profile -o foo_profile --capture-range cudaProfilerApi trtexec --profilingVerbosity=detailed --loadEngine=foo.plan --warmUp=0 --duration=0 --iterations=50
```

The first command builds and serializes the engine to foo.plan, and the second command runs the inference using foo.plan and generates a foo_profile.nsys-rep file that can then be opened in the Nsight Systems user interface for visualization.

The --profilingVerbosity=detailed flag allows TensorRT to show more detailed layer information in the NVTX marking, and the --warmUp=0 --duration=0 --iterations=50 flags allow you to control how many inference iterations to run. By default, trtexec runs inference for three seconds, which may result in a very large output nsys-rep file.

If CUDA graph is enabled, add --cuda-graph-trace=node flag to the nsys command to see the per-kernel runtime information:

```bash
nsys profile -o foo_profile --capture-range cudaProfilerApi --cuda-graph-trace=node trtexec --profilingVerbosity=detailed --loadEngine=foo.plan --warmUp=0 --duration=0 --iterations=50 --useCudaGraph
```

(Optional) Enable GPU Metrics Sampling in Nsight Systems

On discrete GPU systems, add the --gpu-metrics-device all flag to the nsys command to sample GPU metrics, including GPU clock frequencies, DRAM bandwidth, Tensor Core utilization, and so on. If the flag is added, these GPU metrics appear in the Nsight Systems web interface.
13.1.4.1. Profiling for DLA

To profile DLA, add the \texttt{--accelerator-trace nvmedia} flag when using the NVIDIA Nsight Systems CLI or enable \textbf{Collect other accelerators trace} when using the user interface. For example, the following command can be used with the NVIDIA Nsight Systems CLI:

\begin{verbatim}
nsys profile -t cuda,nvtx,nvmedia,osrt --accelerator-trace=nvmedia --show-output=true
trtexec --loadEngine=alexnet_int8.plan --warmUp=0 --duration=0 --iterations=20
\end{verbatim}

Below is an example report.

\begin{itemize}
  \item NvMediaDLASubmit submits a DLA task for each DLA subgraph. The runtime of the DLA task can be found in the DLA timeline under \textbf{Other accelerators trace}.
  \item Because GPU fallback was allowed, some CUDA kernels were added by TensorRT automatically, like \texttt{permutationKernelPLC3} and \texttt{copyPackedKernel}, which are used for data reformatting.
  \item EGLStream APIs were executed because TensorRT uses EGLStreams for data transfer between GPU memory and DLA.
\end{itemize}

To maximize GPU utilization, \texttt{trtexec} enqueues the queries one batch ahead of time.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{sample_dla_profiling_report.png}
\caption{Sample DLA Profiling Report}
\end{figure}

The runtime of the DLA task can be found under \textit{Other accelerator API}. Some CUDA kernels and EGLStream API are called for interaction between the GPU and DLA.
13.1.5. Tracking Memory

Tracking memory usage can be as important as execution performance. Usually, the memory will be more constrained on the device than on the host. To keep track of device memory, the recommended mechanism is to create a simple custom GPU allocator that internally keeps some statistics then uses the regular CUDA memory allocation functions `cudaMalloc` and `cudaFree`.

A custom GPU allocator can be set for the builder `IBuilder` for network optimizations, and for `IRuntime` when deserializing engines using the `IGpuAllocator` APIs. One idea for the custom allocator is to keep track of the current amount of memory allocated, and to push an allocation event with a timestamp and other information onto a global list of allocation events. Looking through the list of allocation events allows profiling memory usage over time.

On mobile platforms, GPU memory and CPU memory share the system memory. On devices with very limited memory size, like Nano, system memory might run out with large networks; even the required GPU memory is smaller than system memory. In this case, increasing the system swap size could solve some problems. An example script is:

```bash
if [ ! -e /swapfile ];then
    echo "######alloc swap######"
    sudo fallocate -l 4G /swapfile
    sudo chmod 600 /swapfile
    sudo mkswap /swapfile
    sudo /bin/sh -c 'echo "/swapfile	none	swap	defaults	0	0" >> /etc/fstab'
    sudo swapon -a
fi
```

13.2. Hardware/Software Environment for Performance Measurements

Performance measurements are influenced by many factors, including hardware environment differences like cooling capability of the machine and software environment differences like GPU clock settings. This section summarizes a few items that may affect performance measurements.

Note that the items involving nvidia-smi are only supported on dGPU systems and not on the mobile systems.
13.2.1. GPU Information Query and GPU Monitoring

While measuring performance, it is recommended that you record and monitor the GPU status in parallel to the inference workload. Having the monitoring data allows you to identify possible root causes when you see unexpected performance measurements results.

Before the inference starts, call the `nvidia-smi -q` command to get the detailed information of the GPU, including the product name, power cap, clock settings, and so on. Then, while the inference workload is running, run the `nvidia-smi dmon -s pcu -f <FILE> -c <COUNT>` command in parallel to print out GPU clock frequencies, power consumption, temperature, and utilization to a file. Call `nvidia-smi dmon --help` for more options about the nvidia-smi device monitoring tool.

13.2.2. GPU Clock Locking and Floating Clock

By default, the GPU clock frequency is floating, meaning that the clock frequency sits at the idle frequency when there is no active workload, and it boosts to the boost clock frequency when the workload starts. This is usually the desired behavior in general since it allows the GPU to generate less heat at idle and to run at maximum speed when there is active workload.

Alternatively, you can lock the clock at a specific frequency by calling the `sudo nvidia-smi -lgc <freq>` command (and conversely, you can let the clock float again with the `sudo nvidia-smi -rgc` command). The supported clock frequencies can be found by the `sudo nvidia-smi -q -d SUPPORTED_CLOCKS` command. After the clock frequency is locked, it should stay at that frequency unless power throttling or thermal throttling take place, which will be explained in next sections. When the throttling kicks in, the device behaves as if the clock were floating.

Running TensorRT workloads with floating clocks or with throttling taking place can lead to more non-determinism in tactic selections and unstable performance measurements across inferences because every CUDA kernel may run at slightly different clock frequencies, depending on which frequency the driver boosts or throttles the clock to at that moment. On the other hand, running TensorRT workloads with locked clocks allows more deterministic tactic selections and consistent performance measurements, but the average performance will not be as good as when the clock is floating or is locked at maximum frequency with throttling taking place.

There is no definite recommendation on whether the clock should be locked or which clock frequency to lock the GPU at while running TensorRT workloads. It depends on whether the deterministic and stable performance or the best average performance is desired.
13.2.3. GPU Power Consumption and Power Throttling

Power throttling occurs when the average GPU power consumption reaches the power limit, which can be set by the `sudo nvidia-smi -pl <power_cap>` command. When this happens, the driver has to throttle the clock to a lower frequency to keep the average power consumption below the limit. The constantly changing clock frequencies may lead to unstable performance measurements if the measurements are taken within a short period of time, such as within 20ms.

Power throttling happens by design and is a natural phenomenon when the GPU clock is not locked or is locked at a higher frequency, especially for the GPUs with lower power limits such as NVIDIA T4 and NVIDIA A2 GPUs. To avoid performance variations caused by power throttling, you can lock the GPU clock at a lower frequency so that the performance numbers become more stable. However, the average performance numbers will be lower than the performance numbers with floating clocks or with the clock locked at a higher frequency even though power throttling would happen in this case.

Another issue with power throttling is that it may skew the performance numbers if there are gaps between inferences in your performance benchmarking applications. For example, if the application synchronizes at each inference, there will be periods of time when the GPU is idle between the inferences. The gaps cause the GPU to consume less power on average such that the clock is throttled less and the GPU can run at higher clock frequencies on average. However, the throughput numbers measured in this way are not accurate because when the GPU is fully loaded with no gaps between inferences, the actual clock frequency will be lower and the actual throughput will not reach the throughput numbers measured using the benchmarking application.

To avoid this, the `trtexec` tool is designed to maximize GPU execution by leaving nearly no gaps between GPU kernel executions so that it can measure the true throughput of a TensorRT workload. Therefore, if you see performance gaps between your benchmarking application and what `trtexec` reports, check if the power throttling and the gaps between inferences are the cause.

Lastly, power consumption can be dependent on the activation values, causing different performance measurements for different inputs. For example, if all the network input values are set to zeros or NaNs, GPU tends to consume less power than if the inputs are normal values because of fewer bit-flips in DRAM and in L2 cache. To avoid this discrepancy, always use the input values that best represent the actual value distribution when measuring the performance. The `trtexec` tool uses random input values by default, but you can specify the input by using the `--loadInputs` flag. Refer to the `trtexec` section for more information.

13.2.4. GPU Temperature and Thermal Throttling

Thermal throttling happens when the GPU temperature reaches a predefined threshold, which is around 85 degrees Celsius for most GPUs, and the driver has to throttle the clock to a lower frequency to prevent the GPU from overheating. You can tell this by seeing the temperature logged by the `nvidia-smi dmon` command gradually increasing...
while the inference workload is running, until it reaches ~85C and the clock frequency starts to drop.

If thermal throttling happens on actively cooled GPUs like Quadro A8000, then it is possible that the fans on the GPU are broken, or there are obstacles blocking the airflow.

If thermal throttling happens on passively cooled GPUs like NVIDIA A10, then it is likely that the GPUs are not properly cooled. Passively cooled GPUs require external fans or air conditioning to cool down the GPUs, and the airflow must go through the GPUs for effective cooling. Common cooling problems include installing GPUs in a server that is not designed for the GPUs or installing wrong numbers of GPUs into the server. In some cases, the air flows through the “easy path” (that is, the path with the least friction) around the GPUs instead of going through them. Fixing this requires examination of the airflow in the server and installation of airflow guidance if necessary.

Note that higher GPU temperature also leads to more leakage current in the circuits, which increases the power consumed by the GPU at a specific clock frequency. Therefore, for GPUs that are more likely to be power throttled like NVIDIA T4, poor cooling can lead to lower stabilized clock frequency with power throttling, and thus worse performance, even if the GPU clocks have not been thermally throttled yet.

On the other hand, ambient temperature, that is, the temperature of the environment around the server, does not usually affect GPU performance so long as the GPUs are properly cooled, except for GPUs with lower power limit whose performance may be slightly affected.

13.2.5. H2D/D2H Data Transfers and PCIe Bandwidth

On dGPU systems, often the input data must be copied from the host memory to the device memory (H2D) before an inference starts, and the output data must be copied back from device memory to host memory (D2H) after the inference. These H2D/D2H data transfers go through PCIe buses, and they can sometimes influence the inference performance or even become the performance bottleneck. The H2D/D2H copies can also be seen in the Nsight Systems profiles, appearing as cudaMemcpy() or cudaMemcpyAsync() CUDA API calls.

To achieve maximum throughput, the H2D/D2H data transfers should run in parallel to the GPU executions of other inferences so that the GPU does not sit idle when the H2D/D2H copies take place. This can be done by running multiple inferences in different streams in parallel, or by launching H2D/D2H copies in a different stream than the stream used for GPU executions and using CUDA events to synchronize between the streams. The trtexec tool shows as an example for the latter implementation.

When the H2D/D2H copies run in parallel to GPU executions, they can interfere with the GPU executions especially if the host memory is pageable, which is the default case. Therefore, it is recommended that you allocate pinned host memory for the input and output data using cudaHostAlloc() or cudaMallocHost() CUDA APIs.

To check whether the PCIe bandwidth becomes the performance bottleneck, you can check the Nsight Systems profiles and see if the H2D or D2H copies of an inference
query have longer latencies than the GPU execution part. If PCIe bandwidth becomes the performance bottleneck, here are a few possible solutions.

First, check whether the PCIe bus configuration of the GPU is correct in terms of which generation (for example, Gen3 or Gen4) and how many lanes (for example, x8 or x16) are used. Next, try reducing the amount of data that must be transferred using the PCIe bus. For example, if the input images have high resolutions and the H2D copies become the bottleneck, then you can consider transmitting JPEG-compressed images over the PCIe bus and decode the image on the GPUs before the inference workflow, instead of transmitting raw pixels. Finally, you can consider using NVIDIA GPUDirect technology to load data directly from/to the network or the filesystems without going through the host memory.

In addition, if your system has AMD x86_64 CPUs, check the NUMA (Non-Uniform Memory Access) configurations of the machine with `numactl --hardware` command. The PCIe bandwidth between a host memory and a device memory located on two different NUMA nodes is much more limited than the bandwidth between the host/device memory located on the same NUMA node. Allocate the host memory on the NUMA node on which the GPU that the data will be copied to resides. Also, pin the CPU threads that will trigger the H2D/D2H copies on that specific NUMA node.

Note that on mobile platforms, the host, and the device share the same memory, so the H2D/D2H data transfers are not required if the host memory is allocated using CUDA APIs and is pinned instead of being pageable.

By default, the `trtexec` tool measures the latencies of the H2D/D2H data transfers that tell the user if the TensorRT workload may be bottlenecked by the H2D/D2H copies. However, if the H2D/D2H copies affect the stability of the GPU Compute Time, you can add the `--noDataTransfers` flag to disable H2D/D2H transfers to measure only the latencies of the GPU execution part.

### 13.2.6. TCC Mode and WDDM Mode

On Windows machines, there are two driver modes: you can configure the GPU to be in the TCC mode and the WDDM mode. The mode can be specified by calling the `sudo nvidia-smi -dm [0|1]` command, but a GPU connected to a display shall not be configured into TCC mode Refer to the [TCC mode documentation](#) for more information and limitations about TCC mode.

In TCC mode, the GPU is configured to focus on computation work and the graphics support like OpenGL or monitor display are disabled. This is the recommended mode for GPUs that run TensorRT inference workloads. On the other hand, the WDDM mode tends to cause GPUs to have worse and unstable performance results when running inference workloads using TensorRT.

This is not applicable to Linux-based OS.

### 13.2.7. Enqueue-Bound Workloads and CUDA Graphs

The `enqueue()` function of `IExecutionContext` is asynchronous, that is, it returns immediately after all the CUDA kernels are launched without waiting for the completion
of CUDA kernel executions. However, in some cases, the `enqueue()` time can take longer than the actual GPU executions, causing the latency of `enqueue()` calls to become the performance bottleneck. We say that this type of workload is "enqueue-bound". There are two reasons that may cause a workload to be enqueue-bound.

First, if the workload is very tiny in terms of the amount of computations, such as containing convolutions with small I/O sizes, matrix multiplications with small GEMM sizes, or mostly element-wise operations throughout the network, then the workload tends to be enqueue-bound. This is because most CUDA kernels take the CPU and the driver around 5-15 microseconds to launch per kernel, so if each CUDA kernel execution time is only several microseconds long on average, the kernel launching time becomes the main performance bottleneck.

To solve this, try to increase the amount of the computation per CUDA kernel, such as by increasing the batch size. Or you can use CUDA Graphs to capture the kernel launches into a graph and launch the graph instead of calling `enqueueV3()`.

Second, if the workload contains operations that require device synchronizations, such as loops or if-else conditions, then the workload is naturally enqueue-bound. In this case, increasing the batch size may help improve the throughput without increasing the latency much.

In `trtexec`, you can tell that a workload is enqueue-bound if the reported Enqueue Time is close to or longer than the reported GPU Compute Time. In this case, it is recommended that you add the `--useCudaGraph` flag to enable CUDA graphs in `trtexec`, which will reduce the Enqueue Time as long as the workload does not contain any synchronization operations.

### 13.2.8. BlockingSync and SpinWait Synchronization Modes

If the performance is measured with `cudaStreamSynchronize()` or `cudaEventSynchronize()`, the variations in synchronization overhead may lead to variations in performance measurements. This section describes the cause of the variations and how to avoid them.

When `cudaStreamSynchronize()` is called, there are two ways in which the driver waits until the completion of the stream. If the `cudaDeviceScheduleBlockingSync` flag has been set with `cudaSetDeviceFlags()` calls, then the `cudaStreamSynchronize()` uses the blocking-sync mechanism. Otherwise, it uses the spin-wait mechanism.

The similar idea applies to CUDA events. If a CUDA event is created with the `cudaEventDefault` flag, then the `cudaEventSynchronize()` call uses the spin-wait mechanism; and if a CUDA event is created with the `cudaEventBlockingSync` flag, then the `cudaEventSynchronize()` call will use the blocking-sync mechanism.

When the blocking-sync mode is used, the host thread yields to another thread until the device work is done. This allows the CPUs to sit idle to save power or to be used by other CPU workloads when the device is still executing. However, the blocking-sync mode tends to result in relatively unstable overheads in stream/event synchronizations in some OS, which in terms lead to variations in latency measurements.
On the other hand, when the spin-wait mode is used, the host thread is constantly polling until the device work is done. Using spin-wait makes the latency measurements more stable due to shorter and more stable overhead in stream/event synchronizations, but it consumes some CPU computation resources and leads to more power consumption by the CPUs.

Therefore, if you want to reduce CPU power consumption, or if you do not want the stream/event synchronizations to consume CPU resources (for example, you are running other heavy CPU workloads in parallel), use the blocking-sync mode. If you care more about stable performance measurements, use the spin-wait mode.

In `trtexec`, the default synchronization mechanism is blocking-sync mode. Add the `--useSpinWait` flag to enable synchronizations using the spin-wait mode for more stable latency measurements, at the cost of more CPU utilizations and power consumptions.

13.3. Optimizing TensorRT Performance

The following sections focus on the general inference flow on GPUs and some of the general strategies to improve performance. These ideas are applicable to most CUDA programmers but may not be as obvious to developers coming from other backgrounds.

13.3.1. Batching

The most important optimization is to compute as many results in parallel as possible using batching. In TensorRT, a batch is a collection of inputs that can all be processed uniformly. Each instance in the batch has the same shape and flows through the network in exactly the same way. Each instance can, therefore, be trivially computed in parallel.

Each layer of the network will have some amount of overhead and synchronization required to compute forward inference. By computing more results in parallel, this overhead is paid off more efficiently. In addition, many layers are performance-limited by the smallest dimension in the input. If the batch size is one or small, this size can often be the performance-limiting dimension. For example, the FullyConnected layer with $V$ inputs and $K$ outputs can be implemented for one batch instance as a matrix multiply of an $1 \times V$ matrix with a $V \times K$ weight matrix. If $N$ instances are batched, this becomes an $N \times V$ multiplied by the $V \times K$ matrix. The vector-matrix multiplier becomes a matrix-matrix multiplier, which is much more efficient.

Larger batch sizes are almost always more efficient on the GPU. Extremely large batches, such as $N > 2^{16}$, can sometimes require extended index computation and so should be avoided if possible. But generally, increasing the batch size improves total throughput. In addition, when the network contains MatrixMultiply layers or FullyConnected layers, batch sizes of multiples of 32 tend to have the best performance for FP16 and INT8 inference because of the utilization of Tensor Cores, if the hardware supports them.

On NVIDIA Ada Lovelace GPUs or later GPUs, it is possible that decreasing the batch size may improve the throughput significantly if the smaller batch sizes happen to help the GPU to cache the input/output values in the L2 cache. Therefore, try various batch sizes to get the batch size for the optimal performance.
Sometimes batching inference work is not possible due to the organization of the application. In some common applications, such as a server that does inference per request, it can be possible to implement opportunistic batching. For each incoming request, wait for a time $T$. If other requests come in during that time, batch them together. Otherwise, continue with a single instance inference. This type of strategy adds fixed latency to each request but can improve the maximum throughput of the system by orders of magnitude.

The NVIDIA Triton Inference Server provides a simple way to enable dynamic batching with TensorRT engines.

Using batching

If the explicit batch mode is used when the network is created, then the batch dimension is part of the tensor dimensions, and you can specify the range of the batch sizes and the batch size to optimize the engine for by adding optimization profiles. Refer to the Working with Dynamic Shapes section for more details.

If the implicit batch mode is used when the network is created, the IExecutionContext::execute (IExecutionContext.execute in Python) and IExecutionContext::enqueue (IExecutionContext.execute_async in Python) methods take a batch size parameter. The maximum batch size should also be set for the builder when building the optimized network with IBuilder::setMaxBatchSize (Builder.max_batch_size in Python). When calling IExecutionContext::execute or enqueue, the bindings passed as the bindings parameter are organized per tensor and not per instance. In other words, the data for one input instance is not grouped together into one contiguous region of memory. Instead, each tensor binding is an array of instance data for that tensor.

Another consideration is that building the optimized network optimizes for the given maximum batch size. The final result will be tuned for the maximum batch size but will still work correctly for any smaller batch size. It is possible to run multiple build operations to create multiple optimized engines for different batch sizes, then choose which engine to use based on the actual batch size at runtime.

13.3.2. Within-Inference Multi-Streaming

In general, CUDA programming streams are a way of organizing asynchronous work. Asynchronous commands put into a stream are guaranteed to run in sequence but may execute out of order with respect to other streams. In particular, asynchronous commands in two streams may be scheduled to run concurrently (subject to hardware limitations).

In the context of TensorRT and inference, each layer of the optimized final network will require work on the GPU. However, not all layers will be able to fully use the computation capabilities of the hardware. Scheduling requests in separate streams allows work to be scheduled immediately as the hardware becomes available without unnecessary synchronization. Even if only some layers can be overlapped, overall performance will improve.
Starting in TensorRT 8.6, you can use the `IBuilderConfig::setMaxAuxStreams()` API to set the maximum number of auxiliary streams that TensorRT is allowed to use to run multiple layers in parallel. The auxiliary streams are in contrast to the "main stream" provided in the `enqueueV3()` call, and if enabled, TensorRT will run some layers on the auxiliary streams in parallel to the layers running on the mainstream.

For example, to run the inference on at most eight streams (that is, seven auxiliary streams and one mainstream) in total:

**C++**
```cpp
config->setMaxAuxStreams(7)
```

**Python**
```python
config.max_aux_streams = 7
```

Note that this only sets the maximum number of auxiliary streams, however, TensorRT may end up using fewer auxiliary streams than this number if it determines that using more streams does not help.

To get the actual number of auxiliary streams that TensorRT uses for an engine, run:

**C++**
```cpp
int32_t nbAuxStreams = engine->getNbAuxStreams()
```

**Python**
```python
num_aux_streams = engine.num_aux_streams
```

When an execution context is created from the engine, TensorRT automatically creates the auxiliary streams needed to run the inference. However, you can also specify the auxiliary streams you would like TensorRT to use:

**C++**
```cpp
int32_t nbAuxStreams = engine->getNbAuxStreams();
std::vector<cudaStream_t> streams(nbAuxStreams);
for (int32_t i = 0; i < nbAuxStreams; ++i)
{
    cudaStreamCreate(&streams[i]);
}
context->setAuxStreams(streams.data(), nbAuxStreams);
```

**Python**
```python
from cuda import cudart
num_aux_streams = engine.num_aux_streams
streams = []
for i in range(num_aux_streams):
    err, stream = cudart.cudaStreamCreate()
    streams.append(stream)
context.set_aux_streams(streams)
```

TensorRT will always insert event synchronizations between the main stream provided using `enqueueV3()` call and the auxiliary streams:

- At the beginning of the `enqueueV3()` call, TensorRT will make sure that all the auxiliary streams wait on the activities on the mainstream.
- At the end of the `enqueueV3()` call, TensorRT will make sure that the main stream waits on the activities on all the auxiliary streams.

Note that enabling auxiliary streams may increase the memory consumption because some activation buffers will no longer be able to be reused.
13.3.3. Cross-Inference Multi-Streaming

In addition to the within-inference streaming, you can also enable streaming between multiple execution contexts. For example, you can build an engine with multiple optimization profiles and create an execution context per profile. Then, call the `enqueueV3()` function of the execution contexts on different streams to allow them to run in parallel.

Running multiple concurrent streams often leads to situations where several streams share compute resources at the same time. This means that the network may have less compute resources available during inference than when the TensorRT engine was being optimized. This difference in resource availability can cause TensorRT to choose a kernel that is suboptimal for the actual runtime conditions. In order to mitigate this effect, you can limit the amount of available compute resources during engine creation to more closely resemble actual runtime conditions. This approach generally promotes throughput at the expense of latency. For more information, refer to Limiting Compute Resources.

It is also possible to use multiple host threads with streams. A common pattern is incoming requests dispatched to a pool of waiting for worker threads. In this case, the pool of worker threads will each have one execution context and CUDA stream. Each thread will request work in its own stream as the work becomes available. Each thread will synchronize with its stream to wait for results without blocking other worker threads.

13.3.4. CUDA Graphs

CUDA graphs are a way to represent a sequence (or more generally a graph) of kernels in a way that allows their scheduling to be optimized by CUDA. This can be particularly useful when your application performance is sensitive to the CPU time taken to enqueue the kernels.

TensorRT’s `enqueueV3()` method supports CUDA graph capture for models that require no CPU interaction mid-pipeline. For example:

**C++**

```c++
// Call enqueueV3() once after an input shape change to update internal state.
context->enqueueV3(stream);

// Capture a CUDA graph instance
cudaGraph_t graph;
cudaGraphExec_t instance;
cudaStreamBeginCapture(stream, cudaStreamCaptureModeGlobal);
context->enqueueV3(stream);
cudaStreamEndCapture(stream, &graph);
cudaGraphInstantiate(&instance, graph, 0);

// To run inferences, launch the graph instead of calling enqueueV3().
for (int i = 0; i < iterations; ++i) {
    cudaGraphLaunch(instance, stream);
    cudaStreamSynchronize(stream);
}
```

**Python**

```python
from cuda import cudart
err, stream = cudart.cudaStreamCreate()

# Call execute_async_v3() once after an input shape change to update internal state.
context.execute_async_v3(stream);
```
# Capture a CUDA graph instance
```
cudaStreamBeginCapture(stream, cudart.cudaStreamCaptureModeGlobal)
context.execute_async_v3(stream)
```
```
er, graph = cudart.cudaStreamEndCapture(stream)
er, instance = cudart.cudaGraphInstantiate(graph, 0)
```
```
# To run inferences, launch the graph instead of calling execute_async_v3().
for i in range(iterations):
    cudart.cudaGraphLaunch(instance, stream)
cudart.cudaStreamSynchronize(stream)
```

Models for which graphs are not supported include those with loops or conditionals. In this case, `cudaStreamEndCapture()` will return `cudaErrorStreamCapture*` errors, indicating that the graph capturing has failed, but the context can continue to be used for normal inference without CUDA graphs.

When capturing a graph, it is important to account for the two-phase execution strategy used in the presence of dynamic shapes.

1. Update internal state of the model to account for any changes in input size.
2. Stream work to the GPU

For models where input size is fixed at build time, the first phase requires no per-invocation work. Otherwise, if the input sizes have changed since the last invocation, some work may be required to update derived properties.

The first phase of work is not designed to be captured, and even if the capture is successful may increase model execution time. Therefore, after changing the shapes of inputs or the values of shape tensors, call `enqueueV3()` once to flush deferred updates before capturing the graph.

Graphs captured with TensorRT are specific to the input size for which they were captured, and also to the state of the execution context. Modifying the context from which the graph was captured will result in undefined behavior when executing the graph - in particular, if the application is providing its own memory for activations using `createExecutionContextWithoutDeviceMemory()`, the memory address is also captured as part of the graph. Binding locations are also captured as part of the graph.

Therefore, the best practice is to use one execution context per captured graph, and to share memory across the contexts with `createExecutionContextWithoutDeviceMemory()`.

`trtexec` allows you to check whether the built TensorRT engine is compatible with CUDA graph capture. Refer to the `trtexec` section for more information.

### 13.3.5. Enabling Fusion

#### 13.3.5.1. Layer Fusion

TensorRT attempts to perform many different types of optimizations in a network during the build phase. In the first phase, layers are fused together whenever possible. Fusions transform the network into a simpler form but preserve the same overall behavior. Internally, many layer implementations have extra parameters and options that are not directly accessible when creating the network. Instead, the fusion optimization step
detects supported patterns of operations and fuses multiple layers into one layer with internal options set.

Consider the common case of a convolution followed by ReLU activation. To create a network with these operations, it involves adding a Convolution layer with `addConvolution`, following it with an Activation layer using `addActivation` with an `ActivationType` of `kRELU`. The unoptimized graph will contain separate layers for convolution and activation. The internal implementation of convolution supports computing the ReLU function on the output in one step directly from the convolution kernel without requiring a second kernel call. The fusion optimization step will detect the convolution followed by ReLU. Verify that the operations are supported by the implementation, then fuse them into one layer.

To investigate which fusions have happened, or have not happened, the builder logs its operations to the logger object provided during construction. Optimization steps are at the `kINFO` log level. To see these messages, ensure you log them in the `ILogger` callback.

Fusions are normally handled by creating a new layer with a name containing the names of both of the layers, which were fused. For example, in MNIST, a FullyConnected layer (InnerProduct) named `ip1` is fused with a ReLU Activation layer named `relu1` to create a new layer named `ip1 + relu1`.

### 13.3.5.2. Types of Fusions
The following list describes the types of supported fusions.

#### Supported Layer Fusions

**ReLU Activation**
- An Activation layer performing ReLU followed by an activation performing ReLU will be replaced by a single activation layer.

**Convolution and ReLU Activation**
- The Convolution layer can be of any type and there are no restrictions on values. The Activation layer must be ReLU type.

**Convolution and GELU Activation**
- The precision of input and output should be the same; with both of them FP16 or INT8. The Activation layer must be GELU type. TensorRT should be running on an NVIDIA Turing or later device with CUDA version 10.0 or later.

**Convolution and Clip Activation**
- The Convolution layer can be any type and there are no restrictions on values. The Activation layer must be Clip type.

**Scale and Activation**
- The Scale layer followed by an Activation layer can be fused into a single Activation layer.

**Convolution and ElementWise Operation**
- A Convolution layer followed by a simple sum, min, or max in an ElementWise layer can be fused into the Convolution layer. The sum must not use broadcasting, unless the broadcasting is across the batch size.
Padding and Convolution/Deconvolution
Padding followed by a Convolution or Deconvolution can be fused into a single Convolution/Deconvolution layer if all the padding sizes are non-negative.

Shuffle and Reduce
A Shuffle layer without reshape, followed by a Reduce layer can be fused into a single Reduce layer. The Shuffle layer can perform permutations but cannot perform any reshape operation. The Reduce layer must have a keepDimensions set of dimensions.

Shuffle and Shuffle
Each Shuffle layer consists of a transpose, a reshape, and a second transpose. A Shuffle layer followed by another Shuffle layer can be replaced by a single Shuffle (or nothing). If both Shuffle layers perform reshape operations, this fusion is only allowed if the second transpose of the first shuffle is the inverse of the first transpose of the second shuffle.

Scale
A Scale layer that adds 0, multiplied by 1, or computes powers to the 1 can be erased.

Convolution and Scale
A Convolution layer followed by a Scale layer that is kUNIFORM or kCHANNEL can be fused into a single convolution by adjusting the convolution weights. This fusion is disabled if the scale has a non-constant power parameter.

Convolution and Generic Activation
This fusion happens after the pointwise fusion mentioned below. A pointwise with one input and one output can be called as a generic activation layer. A convolution layer followed by a generic activation layer can be fused into a single convolution layer.

Reduce
A Reduce layer that performs average pooling will be replaced by a Pooling layer. The Reduce layer must have a keepDimensions set, reduced across H and W dimensions from CHW input format before batching, using the kAVG operation.

Convolution and Pooling
The Convolution and Pooling layers must have the same precision. The Convolution layer may already have a fused activation operation from a previous fusion.

Depthwise Separable Convolution
A depthwise convolution with activation followed by a convolution with activation may sometimes be fused into a single optimized DepSepConvolution layer. The precision of both convolutions must be INT8 and the device’s computes capability must be 7.2 or later.

SoftMax and Log
It can be fused into a single SoftMax layer if the SoftMax has not already been fused with a previous log operation.

SoftMax and TopK
Can be fused into a single layer. The SoftMax may or may not include a Log operation.

FullyConnected
The FullyConnected layer will be converted into the Convolution layer. All fusions for convolution will take effect.
Supported Reduction Operation Fusions

**GEtLU**
A group of Unary layer and ElementWise layer that represents the following equations can be fused into a single GELU reduction operation.

\[
0.5x \times \left(1 + \tanh \left(\frac{2}{\pi} (x + 0.044715x^3)\right)\right)
\]

Or the alternative representation:

\[
0.5x \times \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}}\right)\right)
\]

**L1Norm**
A Unary layer \(kABS\) operation followed by a Reduce layer \(kSUM\) operation can be fused into a single L1Norm reduction operation.

**Sum of Squares**
A product ElementWise layer with the same input (square operation) followed by a \(kSUM\) reduction can be fused into a single square Sum reduction operation.

**L2Norm**
A sum of squares operation followed by a \(kSQRT\) UnaryOperation can be fused into a single L2Norm reduction operation.

**LogSum**
A Reduce layer \(kSUM\) followed by a \(kLOG\) UnaryOperation can be fused into a single LogSum reduction operation.

**LogSumExp**
A Unary \(kEXP\) ElementWise operation followed by a LogSum fusion can be fused into a single LogSumExp reduction.

13.3.5.3. **PointWise Fusion**
Multiple adjacent PointWise layers can be fused into a single PointWise layer, to improve performance.

The following types of PointWise layers are supported, with some limitations:

- **Activation**
  Every ActivationType is supported.

- **Constant**
  Only constant with a single value (size == 1).

- **ElementWise**
  Every ElementWiseOperation is supported.

- **PointWise**
  PointWise itself is also a PointWise layer.

- **Scale**
  Only support ScaleMode::KUNIFORM.

- **Unary**
  Every UnaryOperation is supported.
The size of the fused PointWise layer is not unlimited, therefore, some PointWise layers may not be fused.

Fusion creates a new layer with a name consisting of both of the layers, which were fused. For example, an ElementWise layer named add1 is fused with a ReLU Activation layer named relu1 with a new layer name: fusedPointwiseNode(add1, relu1).

### 13.3.5.4. Q/DQ Fusion

Quantized INT8 graphs generated from QAT tools like NVIDIA's Quantization Toolkit for PyTorch consists of `onnx::QuantizeLinear` and `onnx::DequantizeLinear` pair of nodes (Q/DQ) with scales and zero-points. Starting in TensorRT 7.0, it is required that `zero_point` is 0.

Q/DQ nodes help convert from FP32 values to INT8 and vice versa. Such a graph would still have weights and bias in FP32 precision.

Weights are followed by a Q/DQ node pair so that they can be quantized/dequantized if required. Bias quantization is performed using scales from activations and weights, thus no extra Q/DQ node pair is required for bias input. Assumption for bias quantization is that `S_weights * S_input = S_bias`.

Fusions related to Q/DQ nodes include quantizing/dequantizing weights, commutating Q/DQ nodes without changing the mathematical equivalence of the model, and erasing redundant Q/DQ nodes. After applying Q/DQ fusions, the rest of the builder optimizations would be applied to the graph.

**Fuse Q/DQ with weighted node (Conv, FC, Deconv)**

If we have a

\[
\text{[DequantizeLinear (Activations), DequantizeLinear (weights)] > Node > QuantizeLinear (\[DQ, DQ\] > Node > Q)}
\]

sequence, then it is fused to the quantized node (QNode).

Supporting Q/DQ node pairs for weights requires weighted nodes to support more than one input. Thus we support adding a second input (for weights tensor) and third input (for bias tensor). Additional inputs can be set using `setInput(index, tensor)` API for Convolution, Deconvolution, and FullyConnected layers where index = 2 for weights tensor and index = 3 for bias tensor.

During fusion with weighted nodes, we would quantize FP32 weights to INT8 and fuse it with the corresponding weighted node. Similarly, FP32 bias would be quantized to INT32 and fused.

**Fuse Q/DQ with non-weighted node**

If we have a `DequantizeLinear > Node > QuantizeLinear (DQ > Node > Q)` sequence, then it is fused to the quantized node (QNode).

**Commutate Q/DQ nodes**

DequantizeLinear commutation is allowed when \( \phi (DQ (x)) = DQ (\phi (x)). \)

QuantizeLinear commutation is allowed when \( Q (\phi (x)) = \phi (Q (x)). \)

Also, commutation logic also accounts for available kernel implementations such that mathematical equivalence is guaranteed.
Insert missing Q/DQ nodes
If a node has a missing Q/DQ nodes pair, and \( \max(\|x\|) = \max(\|\phi(x)\|) \) (for example, MaxPool), missing Q/DQ pairs would be inserted to run more node with INT8 precision.

Erase redundant Q/DQ nodes
It is possible that after applying all the optimizations, the graph still has Q/DQ node pairs that are in itself a no-op. Q/DQ node erasure fusion would remove such redundant pairs.

13.3.6. Limiting Compute Resources
Limiting the number of compute resources available to TensorRT during engine creation is beneficial when the reduced amount better represents the expected conditions during runtime. For example, when the GPU is expected to be performing additional work in parallel to the TensorRT engine or when the engine is expected to be run on a different GPU with less resources (note that the recommended approach is to build the engine on the GPU that will be used for inference, but this may not always be feasible).

You can limit the number of available compute resources with the following steps:

1. Start the CUDA MPS control daemon.
   ```bash
nvidia-cuda-mps-control -d
   ```
2. Set the number of compute resources to use with the
   ```bash
   CUDA_MPS_ACTIVE_THREAD_PERCENTAGE
   ```
   environment variable. For example, export
   ```bash
   export CUDA_MPS_ACTIVE_THREAD_PERCENTAGE=50.
   ```
3. Build the network engine.
4. Stop the CUDA MPS control daemon.
   ```bash
   echo quit | nvidia-cuda-mps-control
   ```

The resulting engine is optimized to the reduced number of compute cores (50% in this example) and provides better throughput when using similar conditions during inference. You are encouraged to experiment with different amounts of streams and different MPS values to determine the best performance for your network.

For more details about `nvidia-cuda-mps-control`, refer to the `nvidia-cuda-mps-control` documentation and the relevant GPU requirements here.

13.3.7. Deterministic Tactic Selection
In the engine building phase, TensorRT runs through all the possible tactics and selects the fastest ones. Since the selection is based on the latency measurements of the tactics, TensorRT may end up selecting different tactics across different runs if some tactics have very similar latencies. Therefore, different engines built from the same `INetworkDefinition` may behave slightly differently in terms of output values and performance. You can inspect the selected tactics of an engine by using the `Engine Inspector` or by turning on verbose logging while building the engine.

If deterministic tactic selection is desired, the following lists a few suggestions that may help improve the determinism of tactic selection.
Locking GPU Clock Frequency

By default, the clock frequency of the GPU is not locked, meaning that the GPU normally sits at the idle clock frequency and only boosts to the max clock frequency when there are active GPU workloads. However, there is a latency for the clock to be boosted from the idle frequency and that may cause performance variations while TensorRT is running through the tactics and selecting the best ones, resulting in non-deterministic tactic selections.

Therefore, locking the GPU clock frequency before starting to build a TensorRT engine may improve the determinism of tactic selection. You can lock the GPU clock frequency by calling the `sudo nvidia-smi -lgc <freq>` command, where `<freq>` is the desired frequency to lock at. You can call `nvidia-smi -q -d SUPPORTED_CLOCKS` to find the supported clock frequencies by the GPU.

Therefore, locking the GPU clock frequency before starting to build a TensorRT engine may improve the determinism of tactic selection. Refer to the Hardware/Software Environment for Performance Measurements section for more information about how to lock and monitor the GPU clock and the factors that may affect GPU clock frequencies.

Increasing Average Timing Iterations

By default, TensorRT runs each tactic for at least four iterations and takes the average latency. You can increase the number of iterations by calling the `setAvgTimingIterations()` API:

- **C++**
  ```cpp
  builderConfig->setAvgTimingIterations(8);
  ```

- **Python**
  ```python
  Builder_config.avg_timing_iterations = 8
  ```

Increasing the number of average timing iterations may improve the determinism of tactic selections, but the required engine building time will become longer.

Using Timing Cache

[Timing Cache](#) records the latencies of each tactic for a specific layer configuration. The tactic latencies are reused if TensorRT encounters another layer with an identical configuration. Therefore, by reusing the same timing cache across multiple engine buildings runs with the same INetworkDefinition and builder config, you can make TensorRT select an identical set of tactics in the resulting engines.

Refer to the [Timing Cache](#) section for more information.
13.3.8. Overhead of Shape Change and Optimization Profile Switching

After the IExecutionContext switches to a new optimization profile, or the shapes of the input bindings change, TensorRT must recompute the tensor shapes throughout the network and recompute the resources needed by some tactics for the new shapes before the next inference can start. That means, the first enqueue() call after a shape/profile change may be longer than the subsequent enqueue() calls.

Optimizing the cost of shape/profile switching is an active area of development. However, there are still a few cases where the overhead can influence the performance of the inference applications. For example, some convolution tactics for NVIDIA Volta GPUs or older GPUs have much longer shape/profile switching overhead, even if their inference performance is the best among all the available tactics. In this case, disabling kEDGE_MASK_CONVOLUTIONS tactics from tactic sources when building the engine may help reduce the overhead of shape/profile switching.

13.4. Optimizing Layer Performance

The following descriptions detail how you can optimize the listed layers.

**Concatenation Layer**

If using an implicit batch dimension, the main consideration with the Concatenation layer is that if multiple outputs are concatenated together, they cannot be broadcasted across the batch dimension and must be explicitly copied. Most layers support broadcasting across the batch dimension to avoid copying data unnecessarily, but this will be disabled if the output is concatenated with other tensors.

**Gather Layer**

To get the maximum performance out of a Gather layer, use an axis of 0. There are no fusions available for a Gather layer.

**Reduce Layer**

To get the maximum performance out of a Reduce layer, perform the reduction across the last dimensions (tail reduce). This allows optimal memory to read/write patterns through sequential memory locations. If doing common reduction operations, express the reduction in a way that will be fused to a single operation if possible.

**RNN Layer**

If possible, opt to use the newer RNNv2 interface in preference to the legacy RNN interface. The newer interface supports variable sequence lengths and variable batch sizes, as well as having a more consistent interface. To get maximum performance, larger batch sizes are better. In general, sizes that are multiples of 64 achieve highest performance. Bidirectional RNN-mode prevents wavefront propagation because of the added dependency, therefore, it tends to be slower.

In addition, the newly introduced Loop-based API provides a much more flexible mechanism to use general layers within recurrence without being limited to a small set of predefined RNNv2 interface. The ILoopLayer recurrence enables a rich set of automatic loop optimizations, including loop fusion, unrolling, and loop-invariant code motion, to name a few. For example, significant performance gains are often
obtained when multiple instances of the same MatrixMultiply or FullyConnected layer are properly combined to maximize machine utilization after loop unrolling along the sequence dimension. This works best if you can avoid a MatrixMultiply or FullyConnected layer with a recurrent data dependence along the sequence dimension.

**Shuffle**

Shuffle operations that are equivalent to identity operations on the underlying data are omitted if the input tensor is only used in the shuffle layer and the input and output tensors of this layer are not input and output tensors of the network. TensorRT does not execute additional kernels or memory copies for such operations.

**TopK**

To get the maximum performance out of a TopK layer, use small values of $k$ reducing the last dimension of data to allow optimal sequential memory accesses. Reductions along multiple dimensions at once can be simulated by using a Shuffle layer to reshape the data, then reinterpreting the index values appropriately.

For more information about layers, refer to the [NVIDIA TensorRT Operator’s Reference](https://docs.nvidia.com/deeplearning/sdk/tensorrt/operators/index.html).

# 13.5. Optimizing for Tensor Cores

Tensor Core is a key technology to deliver high-performance inference on NVIDIA GPUs. In TensorRT, Tensor Core operations are supported by all compute-intensive layers - MatrixMultiply, FullyConnected, Convolution, and Deconvolution.

Tensor Core layers tend to achieve better performance if the I/O tensor dimensions are aligned to a certain minimum granularity:

- In Convolution and Deconvolution layers the alignment requirement is on I/O channel dimension.
- In MatrixMultiply and FullyConnected layers the alignment requirement is on matrix dimensions $K$ and $N$ in a MatrixMultiply that is $M \times K$ times $K \times N$.

The following table captures the suggested tensor dimension alignment for better Tensor Core performance.

<table>
<thead>
<tr>
<th>Tensor Core Operation Type</th>
<th>Suggested Tensor Dimension Alignment in Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>TF32</td>
<td>4</td>
</tr>
<tr>
<td>FP16</td>
<td>8 for dense math, 16 for sparse math</td>
</tr>
<tr>
<td>INT8</td>
<td>32</td>
</tr>
</tbody>
</table>

When using Tensor Core implementations in cases where these requirements are not met, TensorRT implicitly pads the tensors to the nearest multiple of alignment rounding up the dimensions in the model definition instead to allow for extra capacity in the model without increasing computation or memory traffic.
TensorRT always uses the fastest implementation for a layer, and thus in some cases may not use a Tensor Core implementation even if available.

To check if Tensor Core is used for a layer, run Nsight Systems with the `--gpu-metrics-device all` flag while profiling the TensorRT application. The Tensor Core usage rate can be found in the profiling result in the Nsight Systems user interface under the **SM instructions/Tensor Active** row. Refer to the [CUDA Profiling Tools](#) for more information about how to use Nsight Systems to profile TensorRT applications.

Note that it is not practical to expect a CUDA kernel to reach 100% Tensor Core usage since there are other overheads such as DRAM reads/writes, instruction stalls, other computation units, and so on. In general, the more computation-intensive an operation is, the higher the Tensor Core usage rate the CUDA kernel can achieve.

The following image is an example of Nsight Systems profiling.

**Figure 21.  Tensor Core Activities on an A100 GPU Running ResNet-50 with FP16 Enabled**

---

### 13.6. Optimizing Plugins

TensorRT provides a mechanism for registering custom plugins that perform layer operations. After a plugin creator is registered, you can look up the registry to find the creator and add the corresponding plugin object to the network during serialization/deserialization.

All TensorRT plugins are automatically registered once the plugin library is loaded. For more information about custom plugins, refer to [Extending TensorRT with Custom Layers](#).

The performance of plugins depends on the CUDA code performing the plugin operation. Standard [CUDA best practices](#) apply. When developing plugins, it can be helpful to
start with simple standalone CUDA applications that perform the plugin operation and verify correctness. The plugin program can then be extended with performance measurements, more unit testing, and alternate implementations. After the code is working and optimized, it can be integrated as a plugin into TensorRT.

To get the best performance possible, it is important to support as many formats as possible in the plugin. This removes the need for internal reformat operations during the execution of the network. Refer to the Extending TensorRT with Custom Layers section for examples.

13.7. Optimizing Python Performance

When using the Python API, most of the same performance considerations apply. When building engines, the builder optimization phase will normally be the performance bottleneck; not API calls to construct the network. Inference time should be nearly identical between the Python API and C++ API.

Setting up the input buffers in the Python API involves using pycuda or another CUDA Python library, like cupy, to transfer the data from the host to device memory. The details of how this works will depend on where the host data is coming from. Internally, pycuda supports the Python Buffer Protocol which allows efficient access to memory regions. This means that if the input data is available in a suitable format in numpy arrays or another type that also has support for the buffer protocol, this allows efficient access and transfer to the GPU. For even better performance, ensure that you allocate a page-locked buffer using pycuda and write your final preprocessed input there.

For more information about using the Python API, refer to The Python API.

13.8. Improving Model Accuracy

TensorRT can execute a layer in FP32, FP16, or INT8 precision depending on the builder configuration. By default, TensorRT chooses to run a layer in a precision that results in optimal performance. Sometimes this can result in poor accuracy. Generally, running a layer in higher precision helps improve accuracy with some performance hit.

There are several steps that we can take to improve model accuracy:

1. Validate layer outputs:
   a). Use Polygraphy to dump layer outputs and verify that there are no NaNs or Infs. The --validate option can check for NaNs and Infs. Also, we can compare layer outputs with golden values from, for example, ONNX runtime.
   b). For FP16, it is possible that a model might require retraining to ensure that intermediate layer output can be represented in FP16 precision without overflow/underflow.
   c). For INT8, consider recalibrating with a more representative calibration data set. If your model comes from PyTorch, we also provide NVIDIA’s Quantization Toolkit for PyTorch for QAT in the framework besides PTQ in TensorRT. You can try both approaches and choose the one with more accuracy.
2. Manipulate layer precision:
   a). Sometimes running a layer in certain precision results in incorrect output. This can be due to inherent layer constraints (for example, LayerNorm output should not be INT8), model constraints (output gets diverged resulting in poor accuracy), or report a [TensorRT bug](#).
   b). You can control layer execution precision and output precision.
   c). An experimental [debug precision](#) tool can help automatically find layers to run in high precision.

3. Use an [Algorithm Selection and Reproducible Builds](#) to disable flaky tactics:
   a). When accuracy changes between build+run to build+run, it might be due to a selection of a bad tactic for a layer.
   b). Use an algorithm selector to dump tactics from both good and bad runs.
      Configure the algorithm selector to allow only a subset of tactics (that is, just allow tactics from a good run, and so on).
   c). You can use Polygraphy to automate this process.

Accuracy from run-to-run variation should not change; once the engine is built for a specific GPU, it should result in bit accurate outputs in multiple runs. If not, file a [TensorRT bug](#).

### 13.9. Optimizing Builder Performance

For each layer, the TensorRT builder profiles all the available tactics to search for the fastest inference engine plan. The builder time can be long if the model has a large number of layers or complicated topology. The following sections provide options to reduce builder time.

#### 13.9.1. Timing Cache

To reduce builder time, TensorRT creates a layer timing cache to keep the layer-profiling information. The information it contains is specific to the targeted device, CUDA, TensorRT versions, and `BuilderConfig` parameters that can change the layer implementation such as `BuilderFlag::kTF32` or `BuilderFlag::kREFIT`.

If there are other layers with the same IO tensor configuration and layer parameters, the TensorRT builder skips profiling and reuses the cached result for the repeated layers. If a timing query misses in the cache, the builder times the layer and updates the cache.

The timing cache can be serialized and deserialized. You can load a serialized cache from a buffer using `IBuilderConfig::createTimingCache`:

```cpp
ITimingCache* cache =
    config->createTimingCache(cacheFile.data(), cacheFile.size());
```

Setting the buffer size to 0 creates a new empty timing cache.

You then attach the cache to a builder configuration before building:

```cpp
config->setTimingCache(*cache, false);
```
During the build, the timing cache can be augmented with more information as a result of cache misses. After the build, it can be serialized for use with another builder.

```cpp
IHostMemory* serializedCache = cache->serialize();
```

If there is no timing cache attached to a builder, the builder creates its own temporary local cache and destroys it when it is done.

The cache is incompatible with algorithm selection (refer to the Algorithm Selection and Reproducible Builds section). It can be disabled by setting the `BuilderFlag`.

```cpp
config->setFlag(BuilderFlag::kDISABLE_TIMING_CACHE);
```

---

**Note:** The timing cache supports the most frequently used layer types: Convolution, Deconvolution, Pooling, SoftMax, MatrixMultiply, ElementWise, Shuffle, and tensor memory layout conversion. More layer types will be added in future releases.

### 13.9.2. Tactic Selection Heuristic

TensorRT allows heuristic-based tactic selection to minimize the builder time in the layer profiling stage. The builder predicts the tactic timing for the given problem size and prunes the tactics that are not likely to be fast prior to the layer profiling stage. In cases where the prediction is wrong, the engine will not be as performant as when built with a profiling-based builder. This feature can be enabled by setting the `BuilderFlag`.

```cpp
config->setFlag(BuilderFlag::kENABLE_TACTIC_HEURISTIC);
```

---

**Note:** The tactic selection heuristic feature is only supported by the NVIDIA Ampere architecture and newer GPUs.

### 13.10. Builder Optimization Level

Set the optimization level in builder config to adjust how long TensorRT should spend searching for tactics with potentially better performance. By default, the optimization level is 3. Setting it to a smaller value results in much faster engine building time, but the performance of the engine may be worse. On the other hand, setting it to a larger value will increase the engine building time, but the resulting engine may perform better if TensorRT is able to find better tactics.

For example, to set the optimization level to 0 (the fastest):

```cpp
config->setOptimizationLevel(0);
```

```python
config.optimization_level = 0
```
Chapter 14. Troubleshooting

The following sections help answer the most commonly asked questions regarding typical use cases.

14.1. FAQs

This section is to help troubleshoot the problem and answer our most asked questions.

Q: How do I create an engine that is optimized for several different batch sizes?

A: While TensorRT allows an engine optimized for a given batch size to run at any smaller size, the performance for those smaller sizes cannot be as well optimized. To optimize for multiple different batch sizes, create optimization profiles at the dimensions that are assigned to OptProfilerSelector::kOPT.

Q: Are calibration tables portable across TensorRT versions?

A: No. Internal implementations are continually optimized and can change between versions. For this reason, calibration tables are not guaranteed to be binary compatible with different versions of TensorRT. Applications must build new INT8 calibration tables when using a new version of TensorRT.

Q: Are engines portable across TensorRT versions?

A: By default, no. Refer to Version Compatibility for how to configure engines for forward compatibility.

Q: How do I choose the optimal workspace size?

A: Some TensorRT algorithms require additional workspace on the GPU. The method IBuilderConfig::setMemoryPoolLimit() controls the maximum amount of workspace that can be allocated and prevents algorithms that require more workspace from being considered by the builder. At runtime, the space is allocated automatically when creating an IExecutionContext. The amount allocated is no more than is required, even if the amount set in IBuilderConfig::setMemoryPoolLimit() is much higher. Applications
should therefore allow the TensorRT builder as much workspace as they can afford; at runtime, TensorRT allocates no more than this and typically less.

**Q: How do I use TensorRT on multiple GPUs?**

**A:** Each `ICudaEngine` object is bound to a specific GPU when it is instantiated, either by the builder or on deserialization. To select the GPU, use `cudaSetDevice()` before calling the builder or deserializing the engine. Each `IExecutionContext` is bound to the same GPU as the engine from which it was created. When calling `execute()` or `enqueue()`, ensure that the thread is associated with the correct device by calling `cudaSetDevice()` if necessary.

**Q: How do I get the version of TensorRT from the library file?**

**A:** There is a symbol in the symbol table named `tensorrt_version_##_##_##` which contains the TensorRT version number. One possible way to read this symbol on Linux is to use the `nm` command like in the following example:

```
$ nm -D libnvinfer.so.* | grep tensorrt_version
00000000abcd1234 B tensorrt_version_##_##_##
```

**Q: What can I do if my network is producing the wrong answer?**

**A:** There are several reasons why your network can be generating incorrect answers. Here are some troubleshooting approaches that can help diagnose the problem:

- Turn on `VERBOSE` level messages from the log stream and check what TensorRT is reporting.
- Check that your input preprocessing is generating exactly the input format required by the network.
- If you are using reduced precision, run the network in FP32. If it produces the correct result, it is possible that lower precision has an insufficient dynamic range for the network.
- Try marking intermediate tensors in the network as outputs, and verify if they match what you are expecting.

**Note:** Marking tensors as outputs can inhibit optimizations, and therefore, can change the results.

You can use [NVIDIA Polygraphy](https://developer.nvidia.com/polygraphy) to assist you with debugging and diagnosis.

**Q: How do I implement batch normalization in TensorRT?**

**A:** Batch normalization can be implemented using a sequence of `IElementWiseLayer` in TensorRT. More specifically:

```plaintext
adjustedScale = scale / sqrt(variance + epsilon)
batchNorm = (input + bias - (adjustedScale * mean)) * adjustedScale
```
Q: Why does my network run slower when using DLA compared to without DLA?
A: DLA was designed to maximize energy efficiency. Depending on the features supported by DLA and the features supported by the GPU, either implementation can be more performant. Which implementation to use depends on your latency or throughput requirements and your power budget. Since all DLA engines are independent of the GPU and each other, you could also use both implementations at the same time to further increase the throughput of your network.

Q: Is INT4 quantization or INT16 quantization supported by TensorRT?
A: Neither INT4 nor INT16 quantization is supported by TensorRT at this time.

Q: When will TensorRT support layer XYZ required by my network in the UFF parser?
A: UFF is deprecated. We recommend users switch their workflows to ONNX. The TensorRT ONNX parser is an open source project.

Q: Can I use multiple TensorRT builders to compile on different targets?
A: TensorRT assumes that all resources for the device it is building on are available for optimization purposes. Concurrent use of multiple TensorRT builders (for example, multiple `trtexec` instances) to compile on different targets (DLA0, DLA1 and GPU) can oversubscribe system resources causing undefined behavior (meaning, inefficient plans, builder failure, or system instability).

It is recommended to use `trtexec` with the `--saveEngine` argument to compile for different targets (DLA and GPU) separately and save their plan files. Such plan files can then be reused for loading (using `trtexec` with the `--loadEngine` argument) and submitting multiple inference jobs on the respective targets (DLA0, DLA1, GPU). This two-step process alleviates over-subscription of system resources during the build phase while also allowing execution of the plan file to proceed without interference by the builder.

Q: Which layers are accelerated by Tensor Cores?
A: Most math-bound operations will be accelerated with tensor cores - convolution, deconvolution, fully connected, and matrix multiply. In some cases, particularly for small channel counts or small group sizes, another implementation may be faster and be selected instead of a tensor core implementation.
Q: Why are reformatting layers observed although there is no warning message no implementation obeys reformatting-free rules ...?

A: Reformat-free network I/O does not mean that there are no reformatting layers inserted in the entire network. Only that the input and output network tensors have a possibility not to require reformatting layers. In other words, reformatting layers can be inserted by TensorRT for internal tensors to improve performance.

14.2. Understanding Error Messages

If an error is encountered during execution, TensorRT reports an error message that is intended to help in debugging the problem. Some common error messages that can be encountered by developers are discussed in the following sections.

UFF Parser Error Messages

The following table captures the common UFF parser error messages.

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The input to the Scale Layer is required to have a minimum of 3 dimensions.</td>
<td>This error message can occur due to incorrect input dimensions. In UFF, input dimensions should always be specified with the implicit batch dimension not included in the specification.</td>
</tr>
<tr>
<td>Invalid scale mode, nbWeights: &lt;X&gt;</td>
<td></td>
</tr>
<tr>
<td>kernel weights has count &lt;X&gt; but &lt;Y&gt; was expected</td>
<td></td>
</tr>
<tr>
<td>&lt;NODE&gt; Axis node has op &lt;OP&gt;, expected Const. The axis must be specified as a Const node.</td>
<td>As indicated by the error message, the axis must be a build time constant in order for UFF to parse the node correctly.</td>
</tr>
</tbody>
</table>

ONNX Parser Error Messages

The following table captures the common ONNX parser error messages. For more information on specific ONNX node support, refer to the operators support document.

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;X&gt; must be an initializer! !inputs.at(X).is_weights()</td>
<td>These error messages signify that an ONNX node input tensor is expected to be an initializer in TensorRT. A possible fix is to run constant folding on the model using TensorRT’s Polygraphy tool:</td>
</tr>
<tr>
<td>getPluginCreator() could not find Plugin &lt;operator name&gt; version 1</td>
<td>This is an error stating that the ONNX parser does not have an import function defined for a particular operator, and did not find a</td>
</tr>
</tbody>
</table>
Table: TensorRT Core Library Error Messages

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Installation Errors</td>
<td></td>
</tr>
<tr>
<td>Cuda initialization failure with error <code>&lt;code&gt;</code>. Please check cuda installation: <a href="http://docs.nvidia.com/cuda/cuda-installation-guide-linux/index.html">http://docs.nvidia.com/cuda/cuda-installation-guide-linux/index.html</a>.</td>
<td>This error message can occur if the CUDA or NVIDIA driver installation is corrupt. Refer to the URL for instructions on installing CUDA and the NVIDIA driver on your OS.</td>
</tr>
<tr>
<td>Internal error: could not find any implementation for node <code>&lt;name&gt;</code>. Try increasing the workspace size with <code>IBuilderConfig::setMemoryPoolLimit()</code>.</td>
<td>This error message occurs because there is no layer implementation for the given node in the network that can operate with the given workspace size. This usually occurs because the workspace size is insufficient but could also indicate a bug. If increasing the workspace size as suggested does not help, report a bug (refer to Reporting TensorRT Issues).</td>
</tr>
<tr>
<td><code>&lt;layer-name&gt;</code>: (kernel</td>
<td>bias) weights has non-zero count but null values</td>
</tr>
<tr>
<td><code>&lt;layer-name&gt;</code>: (kernel</td>
<td>bias) weights has zero count but non-null values</td>
</tr>
<tr>
<td>Builder Errors</td>
<td></td>
</tr>
<tr>
<td>Builder was created on device different from current device.</td>
<td>This error message can show up if you:</td>
</tr>
</tbody>
</table>
### Error Message

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
</table>
| 1. Created an IBuilder targeting one GPU, then  
2. Called cudaSetDevice() to target a different GPU, then  
3. Attempted to use the IBuilder to create an engine.  
Ensure you only use the IBuilder when targeting the GPU that was used to create the IBuilder. |

You can encounter error messages indicating that the tensor dimensions do not match the semantics of the given layer. Carefully read the documentation on `NvInfer.h` on the usage of each layer and the expected dimensions of the tensor inputs and outputs to the layer.

### INT8 Calibration Errors

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
</table>
| Tensor <X> is uniformly zero.  
This warning occurs and should be treated as an error when data distribution for a tensor is uniformly zero. In a network, the output tensor distribution can be uniformly zero under the following scenarios:  
1. Constant tensor with all zero values; not an error.  
2. Activation (ReLU) output with all negative inputs: not an error.  
3. Data distribution is forced to all zero due to computation error in the previous layer; emit a warning here.² |

² It is recommended to evaluate the calibration input or validate the previous layer outputs.
<table>
<thead>
<tr>
<th>Error Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>4. User does not provide any calibration images; emit a warning here.³</td>
<td>This error message indicates that a calibration failure occurred with no scaling factors detected. This could be due to no INT8 calibrator or insufficient custom scales for network layers.</td>
</tr>
<tr>
<td>Could not find scales for tensor &lt;X&gt;.</td>
<td></td>
</tr>
<tr>
<td>Engine Compatibility Errors</td>
<td>The engine plan file is not compatible with this version of TensorRT, expecting (format</td>
</tr>
<tr>
<td>The engine plan file is generated on an incompatible device, expecting compute &lt;X&gt; got compute &lt;Y&gt;, please rebuild.</td>
<td>This error message can occur if you are running TensorRT using an engine PLAN file that is incompatible with the current version of TensorRT. Ensure you use the same version of TensorRT when generating the engine and running it.</td>
</tr>
<tr>
<td>Using an engine plan file across different models of devices is not recommended and is likely to affect performance or even cause errors.</td>
<td>This error message can occur if you build an engine on a device of a different compute capability than the device that is used to run the engine. As indicated by the warning, it is highly recommended to use a device of the same model when generating the engine and deploying it to avoid compatibility issues.</td>
</tr>
<tr>
<td>Out Of Memory Errors</td>
<td>GPU memory allocation failed during initialization of (tensor</td>
</tr>
<tr>
<td>These error messages can occur if there is insufficient</td>
<td></td>
</tr>
</tbody>
</table>

³ It is recommended to evaluate the calibration input or validate the previous layer outputs.
## Troubleshooting

### Error Message

<table>
<thead>
<tr>
<th>Error Message</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPU memory Allocation failed during deserialization of weights.</td>
<td>GPU memory available to instantiate a given TensorRT engine. Verify that the GPU has sufficient available memory to contain the required layer weights and activation tensors.</td>
</tr>
<tr>
<td>GPU does not meet the minimum memory requirements to run this engine...</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>FP16 Errors</th>
<th>Network needs native FP16 and platform does not have native FP16</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This error message can occur if you attempt to deserialize an engine that uses FP16 arithmetic on a GPU that does not support FP16 arithmetic. You either must rebuild the engine without FP16 precision inference or upgrade your GPU to a model that supports FP16 precision inference.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Plugin Errors</th>
<th>Custom layer &lt;name&gt; returned non-zero initialization</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This error message can occur if the initialize() method of a given plugin layer returns a non-zero value. Refer to the implementation of that layer to debug this error further. For more information, refer to the NVIDIA TensorRT Operator’s Reference.</td>
</tr>
</tbody>
</table>

### 14.3. Code Analysis Tools

#### 14.3.1. Compiler Sanitizers

Google sanitizers are a set of code analysis tools.

#### 14.3.1.1. Issues with `dlopen` and Address Sanitizer

There is a known issue with sanitizers, documented here. When using `dlopen` on TensorRT under a sanitizer, there will be reports of memory leaks unless one of two solutions is adopted:

1. Do not call `dlclose` when running under the sanitizers.
2. Pass the flag `RTLD_NODELETE` to `dlopen` when running under sanitizers.
14.3.1.2. Issues with `dlopen` and Thread Sanitizer

The thread sanitizer can list errors when using `dlopen` from multiple threads. In order to suppress this warning, create a file called `tsan.supp` and add the following to the file:

```plaintext
race::dlopen
```

When running applications under thread sanitizer, set the environment variable using:

```bash
export TSAN_OPTIONS="suppressions=tsan.supp"
```

14.3.1.3. Issues with CUDA and Address Sanitizer

The address sanitizer has a known issue with CUDA applications documented here. In order to successfully run CUDA libraries such as TensorRT under the address sanitizer, add the option `protect_shadow_gap=0` to the `ASAN_OPTIONS` environment variable.

On CUDA 11.4, there is a known bug that can trigger mismatched allocation-and-free errors in the address sanitizer. Add `alloc_dealloc_mismatch=0` to `ASAN_OPTIONS` to disable these errors.

14.3.1.4. Issues with Undefined Behavior Sanitizer

UndefinedBehaviorSanitizer (UBSan) reports false positives with the `-fvisibility=hidden` option as documented here. Add the `-fno-sanitize=vptr` option to avoid UBSan reporting such false positives.

14.3.2. Valgrind

Valgrind is a framework for dynamic analysis tools that can be used to automatically detect memory management and threading bugs in applications.

Some versions of valgrind and glibc are affected by a bug, which causes false memory leaks to be reported when `dlopen` is used, which can generate spurious errors when running a TensorRT application under valgrind's `memcheck` tool. To work around this, add the following to a valgrind suppressions file as documented here:

```plaintext
{  
    Memory leak errors with dlopen
    Memcheck:Leak
    match-leak-kinds: definite
    ...  
    fun:*dlopen*
    ...
}
```

On CUDA 11.4, there is a known bug that can trigger mismatched allocation-and-free errors in valgrind. Add the option `--show-mismatched-frees=no` to the valgrind command line to suppress these errors.

14.3.3. Compute Sanitizer

When running a TensorRT application under compute-sanitizer, `cuGetProcAddress` can fail with error code 500 due to missing functions. This error can be ignored or suppressed with `--report-api-errors no` option. This is due to CUDA backward compatibility
checking if a function is usable on the CUDA toolkit/driver combination. The functions are introduced in a later version of CUDA but are not available on the current platform.

14.4. Understanding Formats Printed in Logs

In logs from TensorRT, formats are printed as a type followed by stride and vectorization information. For example:

\[ \text{Half}(60,1:8,12,3) \]

The \text{Half} indicates that the element type is \text{DataType::kHALF}, that is, 16-bit floating point. The :8 indicates the format packs eight elements per vector, and that vectorization is along the second axis. The rest of the numbers are strides in units of vectors. For this tensor, the mapping of a coordinate \((n,c,h,w)\) to an address is:

\[ ((\text{half}*)\text{base\_address}) + (60*n + 1*\text{floor}(c/8) + 12*h + 3*w) * 8 + (c \mod 8) \]

The 1: is common to NHWC formats. For example, here is another example for an NCHW format:

\[ \text{Int8}(105,15:4,3,1) \]

The \text{INT8} indicates that the element type is \text{DataType::kINT8}, and the :4 indicates a vector size of 4. For this tensor, the mapping of a coordinate \((n,c,h,w)\) to an address is:

\[ (\text{int8\_t}*)\text{base\_address} + (105*n + 15*\text{floor}(c/4) + 3*h + w) * 4 + (c \mod 4) \]

Scalar formats have a vector size of 1. For brevity, printing omits the :1.

In general, the coordinates to address mappings have the following form:

\[(\text{type}*)\text{base\_address} + (\text{vec\_coordinate} \cdot \text{strides}) \cdot \text{vec\_size} + \text{vec\_mod}\]

Where:

- the dot denotes an inner product
- strides are the printed strides, that is, strides in units of vectors
- \text{vec\_size} is the number of elements per vectors
- \text{vec\_coordinate} is the original coordinate with the coordinate along the vectorized axis divided by \text{vec\_size}
- \text{vec\_mod} is the original coordinate along the vectorized axis modulo \text{vec\_size}

14.5. Reporting TensorRT Issues

If you encounter issues when using TensorRT, first confirm that you have followed the instructions in this Developer Guide. Also, check the FAQs and the Understanding Error Messages sections to look for similar failing patterns. For example, many engine building failures can be solved by sanitizing and constant-folding the ONNX model using Polygraphy with the following command:

\[ \text{polygraphy surgeon sanitize model.onnx --fold-constants --output model\_folded.onnx} \]
In addition, it is highly recommended that you first try our latest TensorRT release before filing an issue if you have not done so, since your issue may have been fixed in the latest release.

14.5.1. Channels for TensorRT Issue Reporting

If none of the FAQs or the Understanding Error Messages work, there are two main channels where you can report the issue: NVIDIA Developer Forum or TensorRT GitHub Issue page. These channels are constantly monitored to provide feedback to the issues you encountered.

Here are the steps to report an issue on the NVIDIA Developer Forum:

1. Register for the NVIDIA Developer website.
2. Log in to the developer site.
3. Click on your name in the upper right corner.
4. Click My account > My Bugs and select Submit a New Bug.
5. Fill out the bug reporting page. Be descriptive and if possible, provide the steps to reproduce the problem.
6. Click Submit a bug.

When reporting an issue, provide setup details and include the following information:

- Environment information:
  - OS or Linux distro and version
  - GPU type
  - NVIDIA driver version
  - CUDA version
  - cuDNN version
  - Python version (if Python is used).
  - TensorFlow, PyTorch, and ONNX version (if any of them is used).
  - TensorRT version
  - NGC TensorRT container version (if TensorRT container is used).
  - Jetson (if used), include OS and hardware versions
- Thorough description of the issue.
- Steps to reproduce the issue:
  - ONNX file (if ONNX is used).
  - Minimal commands or scripts to trigger the issue
  - Verbose logs by enabling kVERBOSE in ILogger

Depending on the type of the issue, providing more information listed below can expedite the response and debugging process.
14.5.2. Reporting a Functional Issue

When reporting functional issues, such as linker errors, segmentation faults, engine building failures, inference failures, and so on, provide the scripts and the commands to reproduce the issue as well as the detailed description of the environment. Having more details helps us in debugging the functional issue faster.

Since the TensorRT engine is specific to a specific TensorRT version and a specific GPU type, do not build the engine in one environment and use it to run it in another environment with different GPUs or dependency software stack, such as TensorRT version, CUDA version, cuDNN version, and so on. Also, ensure that the application is linked to the correct TensorRT and cuDNN shared object files by checking the environment variable `LD_LIBRARY_PATH` (or `%PATH%` on Windows).

14.5.3. Reporting an Accuracy Issue

When reporting an accuracy issue, provide the scripts and the commands used to calculate the accuracy metrics. Describe what the expected accuracy level is and, if possible, share the steps to get the expected results using other frameworks like ONNX-Runtime.

The Polygraphy tool can be used to debug the accuracy issue and produce a minimal failing case. Refer to the Debugging TensorRT Accuracy Issues documentation for the instructions. Having a Polygraphy command that shows the accuracy issue or having the minimal failing case expedites the time it takes for us to debug your accuracy issue.

Note that it is not practical to expect bitwise identical results between TensorRT and other frameworks like PyTorch, TensorFlow, or ONNX-Runtime even in FP32 precision since the order of the computations on the floating-point numbers can result in slight differences in output values. In practice, small numeric differences should not significantly affect the accuracy metric of the application, such as the mAP score for object-detection networks or the BLEU score for translation networks. If you do see a significant drop in the accuracy metric between using TensorRT and using other frameworks such as PyTorch, TensorFlow, or ONNX-Runtime, it may be a genuine TensorRT bug.

If you are seeing NaNs or infinite values in TensorRT engine output when FP16 precision is enabled, it is possible that intermediate layer outputs in the network overflow in FP16. Some approaches to help mitigate this include:

- Ensure that network weights and inputs are restricted to a reasonably narrow range (such as [-1, 1] instead of [-100, 100]). This may require making changes to the network and retraining.
- Consider pre-processing input by scaling or clipping it to the restricted range before passing it to the network for inference.
- Overriding precision for individual layers vulnerable to overflows (for example, Reduce and Element-Wise Power ops) to FP32.

Polygraphy can help you diagnose common problems with using reduced precision. Refer to Polygraphy’s Working with Reduced Precision how-to guide for more details.
Refer to the Improving Model Accuracy section for some possible solutions to accuracy issues, and the Working with INT8 section for instructions about using INT8 precision.

14.5.4. Reporting a Performance Issue

If you are reporting a performance issue, share the full `trtexec` logs using this command:

```
trtexec --onnx=<onnx_file> <precision_and_shape_flags> --verbose --
profilingVerbosity=detailed --dumpLayerInfo --dumpProfile --separateProfileRun --useCudaGraph
--noDataTransfers --useSpinWait --duration=60
```

The verbose logs help us to identify the performance issue. If possible, also share the Nsight Systems profiling files using these commands:

```
trtexec --onnx=<onnx_file> <precision_and_shape_flags> --verbose --
profilingVerbosity=detailed --dumpLayerInfo --saveEngine=<engine_path>
nsys profile --cuda-graph-trace=node -o <output_profile> trtexec --loadEngine=<engine_path>
<precision_and_shape_flags> --useCudaGraph --noDataTransfers --useSpinWait --warmUp=0 --
duration=0 --iterations=20
```

Refer to the `trtexec` section for more instructions about how to use the `trtexec` tool and the meaning of these flags.

If you do not use `trtexec` to measure performance, provide the scripts and the commands that you use to measure the performance. If possible, compare the performance measurement from your script with that from the `trtexec` tool. If the two numbers differ, there may be some issues about the performance measurement methodology in your scripts.

Refer to the Hardware/Software Environment for Performance Measurements section for some environment factors that may affect the performance.
A.1. Data Format Descriptions

TensorRT supports different data formats. There are two aspects to consider: data type and layout.

**Data Type Format**

The data type is the representation of each individual value. Its size determines the range of values and the precision of the representation, which are FP32 (32-bit floating point, or single precision), FP16 (16-bit floating point or half precision), INT32 (32-bit integer representation), and INT8 (8-bit representation).

**Layout Format**

The layout format determines the ordering in which values are stored. Typically, batch dimensions are the leftmost dimensions, and the other dimensions refer to aspects of each data item, such as \( C \) is channel, \( H \) is height, and \( W \) is width, in images. Ignoring batch sizes, which are always preceding these, \( C \), \( H \), and \( W \) are typically sorted as \( CHW \) (refer to Figure 22) or \( HWC \) (refer to Figure 23).

The following image is divided into \( H \times W \) matrices, one per channel, and the matrices are stored in sequence; all the values of a channel are stored contiguously.
Figure 22. Layout Format for \(CHW\)

The image is stored as a single \(H \times W\) matrix, whose value is actually C-tuple, with a value per channel; all the values of a point (pixel) are stored contiguously.
To enable faster computations, more formats are defined to pack together channel values and use reduced precision. For this reason, TensorRT also supports formats like NC, 2HW2 and NHWC8.

In NC, 2HW2 (TensorFormat::kCHW2), pairs of channel values are packed together in each HxW matrix (with an empty value in the case of an odd number of channels). The result is a format in which the values of \#C/2\# HxW matrices are pairs of values of two consecutive channels (refer to Figure 24); notice that this ordering interleaves dimension as values of channels that have stride 1 if they are in the same pair and stride 2xHxW otherwise.

A pair of channel values is packed together in each HxW matrix. The result is a format in which the values of \#C/2\# HxW matrices are pairs of values of two consecutive channels.

Figure 23. Layout format for HWC
Figure 24. Values of $\#C/2\#_{\text{HxW}}$ Matrices are Pairs of Values of Two Consecutive Channels

In NHWC8 (TensorFormat::kHW8), the entries of an $\text{HxW}$ matrix include the values of all the channels (refer to Figure 25). In addition, these values are packed together in $\#C/8\#$ 8-tuples, and $C$ is rounded up to the nearest multiple of 8.

In this NHWC8 format, the entries of an $\text{HxW}$ matrix include the values of all the channels.
Figure 25. In NHWC8 Format, the Entries of an HxW Matrix Include the Values of all the Channels

Other TensorFormat follow similar rules to TensorFormat::kCHW2 and TensorFormat::kHWC8 mentioned previously.

A.2. Command-Line Programs

A.2.1. trtexec

Included in the samples directory is a command-line wrapper tool called trtexec. trtexec is a tool to quickly utilize TensorRT without having to develop your own application. The trtexec tool has three main purposes:

- It is useful for benchmarking networks on random or user-provided input data.
- It is useful for generating serialized engines from models.
- It is useful for generating serialized timing cache from the builder.
A.2.1.1. Benchmarking Network

If you have a model saved as an ONNX file, UFF file, or if you have a network description in a Caffe prototxt format, you can use the `trtexec` tool to test the performance of running inference on your network using TensorRT. The `trtexec` tool has many options for specifying inputs and outputs, iterations for performance timing, precision allowed, and other options.

To maximize GPU utilization, `trtexec` enqueues the inferences one batch ahead of time. In other words, it does the following:

```
enqueue batch 0 -> enqueue batch 1 -> wait until batch 0 is done -> enqueue batch 2 -> wait
    until batch 1 is done -> enqueue batch 3 -> wait until batch 2 is done -> enqueue batch 4 -> ...
```

If `cross-inference multi-stream` (`--infStreams=N` flag) is used, then `trtexec` follows this pattern on each stream separately.

The `trtexec` tool prints the following performance metrics. The following figure shows an example Nsight System profile of a `trtexec` run with markers showing what each performance metric means.

**Throughput**

The observed throughput is computed by dividing the number of inferences by the Total Host Walltime. If this is significantly lower than the reciprocal of GPU Compute Time, the GPU may be underutilized because of host-side overheads or data transfers. Using CUDA graphs (with `--useCudaGraph`) or disabling H2D/D2H transfers (with `--noDataTransfer`) may improve GPU utilization. The output log provides guidance on which flag to use when `trtexec` detects that the GPU is underutilized.

**Host Latency**

The summation of H2D Latency, GPU Compute Time, and D2H Latency. This is the latency to infer a single inference.

**Enqueue Time**

The host latency to enqueue an inference, including calling H2D/D2H CUDA APIs, running host-side heuristics, and launching CUDA kernels. If this is longer than GPU Compute Time, the GPU may be underutilized and the throughput may be dominated by host-side overhead. Using CUDA graphs (with `--useCudaGraph`) may reduce enqueue time.

**H2D Latency**

The latency for host-to-device data transfers for input tensors of a single inference. Add `--noDataTransfer` to disable H2D/D2H data transfers.

**D2H Latency**

The latency for device-to-host data transfers for output tensors of a single inference. Add `--noDataTransfer` to disable H2D/D2H data transfers.

**GPU Compute Time**

The GPU latency to execute the CUDA kernels for an inference.

**Total Host Walltime**

The host walltime from when the first inference (after warm-ups) is enqueued to when the last inference was completed.
**Total GPU Compute Time**

The summation of the GPU Compute Time of all the inferences. If this is significantly shorter than Total Host Walltime, the GPU may be under utilized because of host-side overheads or data transfers.

Performance metrics in a normal `trtexec` run under Nsight Systems (ShuffleNet, BS=16, best, TitanRTX at 1200 MHz).

> **Note:** In the latest Nsight Systems, the GPU rows appear above the CPU rows rather than beneath the CPU rows.

**Figure 26.** Performance Metrics in a Normal `trtexec` Run under Nsight Systems

Add the `--dumpProfile` flag to `trtexec` to show per-layer performance profiles, which allows users to understand which layers in the network take the most time in GPU execution. The per-layer performance profiling works with launching inference as a CUDA graph as well. In addition, build the engine with the `--profilingVerbosity=detailed` flag and add the `--dumpLayerInfo` flag to show detailed engine information, including per-layer detail and binding information. This allows you to understand which operation each layer in the engine corresponds to and their parameters.
A.2.1.2. Serialized Engine Generation

If you generate a saved serialized engine file, you can pull it into another application that runs inference. For example, you can use the NVIDIA Triton Inference Server to run the engine with multiple execution contexts from multiple threads in a fully pipelined asynchronous way to test parallel inference performance. There are some caveats; for example, in INT8 mode, trtexec sets random dynamic ranges for tensors unless the calibration cache file is provided with the --calib=<file> flag, so the resulting accuracy will not be as expected.

A.2.1.3. Serialized Timing Cache Generation

If you provide a timing cache file to the --timingCacheFile option, the builder can load existing profiling data from it and add new profiling data entries during layer profiling. The timing cache file can be reused in other builder instances to improve the builder execution time. It is suggested to reuse this cache only in the same hardware/software configurations (for example, CUDA/cuDNN/TensorRT versions, device model, and clock frequency); otherwise, functional or performance issues may occur.

A.2.1.4. Commonly Used Command-line Flags

The section lists the commonly used trtexec command-line flags.

Flags for the Build Phase

- --onnx=<model>: Specify the input ONNX model.
- --deploy=<caffe prototxt>: Specify the input Caffe prototxt model.
- --uff=<model>: Specify the input UFF model.
- --output=<tensor>: Specify output tensor names. Only required if the input models are in UFF or Caffe formats.
- --maxBatch=<BS>: Specify the maximum batch size to build the engine with. Only needed if the input models are in UFF or Caffe formats. If the input model is in ONNX format, use the --minShapes, --optShapes, and --maxShapes flags to control the range of input shapes including batch size.
- --minShapes=<shapes>, --optShapes=<shapes>, and --maxShapes=<shapes>: Specify the range of the input shapes to build the engine with. Only required if the input model is in ONNX format.
- --memPoolSize=<pool_spec>: Specify the maximum size of the workspace that tactics are allowed to use, as well as the sizes of the memory pools that DLA will allocate per loadable.
- --saveEngine=<file>: Specify the path to save the engine to.
- --sparsity=[disable|enable|force]: Specify whether to use tactics that support structured sparsity.
disable: Disable all tactics using structured sparsity. This is the default.
enable: Enable tactics using structured sparsity. Tactics will only be used if the weights in the ONNX file meet the requirements for structured sparsity.
force: Enable tactics using structured sparsity and allow trtexec to overwrite the weights in the ONNX file to enforce them to have structured sparsity patterns. Note that the accuracy is not preserved, so this is to get inference performance only.

--timingCacheFile=<file>: Specify the timing cache to load from and save to.
--verbose: Turn on verbose logging.
--skipInference: Build and save the engine without running inference.
--profilingVerbosity=[layer_names_only|detailed|none]: Specify the profiling verbosity to build the engine with.
--dumpLayerInfo,--exportLayerInfo=<file>: Print/Save the layer information of the engine.
--precisionConstraints=spec: Control precision constraint setting.
  none: No constraints.
  prefer: Meet precision constraints set by --layerPrecisions/--layerOutputTypes if possible.
  obey: Meet precision constraints set by --layerPrecisions/--layerOutputTypes or fail otherwise.
--layerPrecisions=spec: Control per-layer precision constraints. Effective only when precisionConstraints is set to obey or prefer. The specs are read left to right, and later ones override earlier ones. "*" can be used as a layerName to specify the default precision for all the unspecified layers.
  For example: --layerPrecisions=*:fp16,layer_1:fp32 sets the precision of all layers to FP16 except for layer_1, which will be set to FP32.
--layerOutputTypes=spec: Control per-layer output type constraints. Effective only when precisionConstraints is set to obey or prefer. The specs are read left to right, and later ones override earlier ones. "*" can be used as a layerName to specify the default precision for all the unspecified layers. If a layer has more than one output, then multiple types separated by "+" can be provided for this layer.
  For example: --layerOutputTypes=*:fp16,layer_1:fp32+fp16 sets the precision of all layer outputs to FP16 except for layer_1, whose first output will be set to FP32 and whose second output will be set to FP16.
--layerDeviceTypes=spec: Explicitly set per-layer device type to either GPU or DLA. The specs are read left to right, and later ones override earlier ones.
--useDLACore=N: Use the specified DLA core for layers that support DLA.
--allowGPUBackup: Allow layers unsupported on DLA to run on GPU instead.
Appendix

NVIDIA TensorRT

---

- **--versionCompatible, --vc**: Enable version compatible mode for engine build and inference. Any engine built with this flag enabled is compatible with newer versions of TensorRT on the same host OS when run with TensorRT’s dispatch and lean runtimes. Only supported with explicit batch mode.

- **--excludeLeanRuntime**: When **--versionCompatible** is enabled, this flag indicates that the generated engine should not include an embedded lean runtime. If this is set, you must explicitly specify a valid lean runtime to use when loading the engine. Only supported with explicit batch and weights within the engine.

- **--tempdir=<dir>**: Overrides the default temporary directory TensorRT will use when creating temporary files. Refer to the `IRuntime::setTemporaryDirectory` API documentation for more information.

- **--tempfileControls=controls**: Controls what TensorRT is allowed to use when creating temporary executable files. Should be a comma-separated list with entries in the format `[in_memory|temporary]:[allow|deny]`.

  - Options include:
    - **in_memory**: Controls whether TensorRT is allowed to create temporary in-memory executable files.
    - **temporary**: Controls whether TensorRT is allowed to create temporary executable files in the filesystem (in the directory given by **--tempdir**).

  - Example usage: `--tempfileControls=in_memory:allow, temporary:deny`

- **--dynamicPlugins=<file>**: Load the plugin library dynamically and serialize it with the engine when it is included in **--setPluginsToSerialize** (can be specified multiple times).

- **--setPluginsToSerialize=<file>**: Set the plugin library to be serialized with the engine (can be specified multiple times).

- **--builderOptimizationLevel=N**: Set the builder optimization level to build the engine with. Higher level allows TensorRT to spend more building time for more optimization options.

- **--maxAuxStreams=N**: Set maximum number of auxiliary streams per inference stream that TRT is allowed to use to run kernels in parallel if the network contains ops that can run in parallel, with the cost of more memory usage. Set this to 0 for optimal memory usage. Refer to the Within-Inference Multi-Streaming section for more information.

**Flags for the Inference Phase**

- **--loadEngine=<file>**: Load the engine from a serialized plan file instead of building it from input ONNX, UFF, or Caffe model.

- **--batch=<N>**: Specify the batch size to run the inference with. Only needed if the input models are in UFF or Caffe formats. If the input model is in ONNX format or if the engine is built with explicit batch dimension, use **--shapes** instead.
Appendix

NVIDIA TensorRT

--shapes=<shapes>: Specify the input shapes to run the inference with.

--loadInputs=<specs>: Load input values from files. Default is to generate random inputs.

--warmUp=<duration in ms>, --duration=<duration in seconds>, --iterations=<N>: Specify the minimum duration of the warm-up runs, the minimum duration for the inference runs, and the minimum iterations of the inference runs. For example, setting --warmUp=0 --duration=0 --iterations=N allows you to control exactly how many iterations to run the inference for.

--useCudaGraph: Capture the inference to a CUDA graph and run inference by launching the graph. This argument may be ignored when the built TensorRT engine contains operations that are not permitted under CUDA graph capture mode.

--noDataTransfers: Turn off host to device and device-to-host data transfers.

--useSpinWait: Actively synchronize on GPU events. This option makes latency measurement more stable but increases CPU usage and power.

--infStreams=<N>: Run inference with multiple cross-inference streams in parallel. Refer to the Cross-Inference Multi-Streaming section for more information.

--verbose: Turn on verbose logging.

--dumpProfile, --exportProfile=<file>: Print/Save the per-layer performance profile.

--dumpLayerInfo, --exportLayerInfo=<file>: Print layer information of the engine.

--profilingVerbosity=[layer_names_only|detailed|none]: Specify the profiling verbosity to run the inference with.

--useRuntime=[full|lean|dispatch]: TensorRT runtime to execute engine. lean and dispatch require --versionCompatible to be enabled and are used to load a VC engine. All engines (VC or not) must be built with full runtime.

--leanDLLPath=<file>: External lean runtime DLL to use in version compatible mode. Requires --useRuntime=[lean|dispatch].

--dynamicPlugins=<file>: Load the plugin library dynamically when the library is not included in the engine plan file (can be specified multiple times).

Refer to `trtexec --help` for all the supported flags and detailed explanations.

Refer to the [GitHub: trtexec/README.md](https://github.com/NVIDIA/TensorRT/tree/main/trtexec) file for detailed information about how to build this tool and examples of its usage.

A.3. Glossary

**Data-Dependent Shape**

A tensor shape with a dynamic dimension that is not calculated solely from network input dimensions and network input shape tensors.
Device
A specific GPU. Two GPUs are considered identical devices if they have the same model name and same configuration.

Explicitly Data-Dependent Shape
A tensor shape that depends on the dimensions of an output of INonZeroLayer or INMSLayer.

Implicitly Data-Dependent Shape
A tensor shape with a dynamic dimension that is calculated from data other than network input dimensions, network input shape tensors, and INonZeroLayer or INMSLayer. For example, a shape with a dimension calculated from data output by a convolution.

Platform
A combination of architecture and OS. Example platforms are Linux on x86 and QNX Standard on Aarch64. Platforms with different architectures or different OS are considered different platforms.

A.4. ACKNOWLEDGEMENTS

TensorRT uses elements from the following software, whose licenses are reproduced below.

Google Protobuf

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution
as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner
that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that
control, are controlled by, or are under common control with that entity. For the
purposes of this definition, "control" means (i) the power, direct or indirect, to cause
the direction or management of such entity, whether by contract or otherwise, or (ii)
ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial
ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions
granted by this License.

"Source" form shall mean the preferred form for making modifications, including but
not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or
translation of a Source form, including but not limited to compiled object code,
generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made
available under the License, as indicated by a copyright notice that is included in or
attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is
based on (or derived from) the Work and for which the editorial revisions, annotations,
elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

   a). You must give any other recipients of the Work or Derivative Works a copy of this License; and
b). You must cause any modified files to carry prominent notices stating that You changed the files; and

c). You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

d). If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License. You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NONINFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright 2014 Google Inc.

Licensed under the Apache License, Version 2.0 (the "License"); you may not use this file except in compliance with the License. You may obtain a copy of the License at: http://www.apache.org/licenses/LICENSE-2.0.

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

The Institute of Electrical and Electronics Engineers and the American National Standards
Committee X3, on Information Processing Systems have given us permission to reprint
portions of their documentation.

In the following statement, the phrase `this text' refers to portions of the system
documentation.

Portions of this text are reprinted and reproduced in electronic form in the second
Operating System Interface for Computer Environments (POSIX), copyright C 1988 by
the Institute of Electrical and Electronics Engineers, Inc. In the event of any discrepancy between these versions and the original IEEE Standard, the original IEEE Standard is the referee document.

In the following statement, the phrase `This material' refers to portions of the system documentation.

This material is reproduced with permission from American National Standards Committee X3, on Information Processing Systems. Computer and Business Equipment Manufacturers Association (CBEMA), 311 First St., NW, Suite 500, Washington, DC 20001-2178. The developmental work of Programming Language C was completed by the X3J11 Technical Committee.

The views and conclusions contained in the software and documentation are those of the authors and should not be interpreted as representing official policies, either expressed or implied, of the Regents of the University of California.

Note: The copyright of UC Berkeley’s Berkeley Software Distribution (“BSD”) source has been updated. The copyright addendum may be found at ftp://ftp.cs.berkeley.edu/pub/4bsd/README.Impt.License.Change and is included below.

July 22, 1999
To All Licensees, Distributors of Any Version of BSD:

As you know, certain of the Berkeley Software Distribution (“BSD”) source code files require that further distributions of products containing all or portions of the software, acknowledge within their advertising materials that such products contain software developed by UC Berkeley and its contributors.

Specifically, the provision reads:

" 3. All advertising materials mentioning features or use of this software
   must display the following acknowledgement:
   * This product includes software developed by the University of
   * California, Berkeley and its contributors."

Effective immediately, licensees and distributors are no longer required to include the acknowledgement within advertising materials. Accordingly, the foregoing paragraph of those BSD Unix files containing it is hereby deleted in its entirety.

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works
thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

a). You must give any other recipients of the Work or Derivative Works a copy of this License; and

b). You must cause any modified files to carry prominent notices stating that You changed the files; and

c). You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
d). If the Work includes a “NOTICE” text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other
9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

Notice

This document is provided for information purposes only and shall not be regarded as a warranty of a certain functionality, condition, or quality of a product. NVIDIA Corporation ("NVIDIA") makes no representations or warranties, expressed or implied, as to the accuracy or completeness of the information contained in this document and assumes no responsibility for any errors contained herein. NVIDIA shall have no liability for the consequences or use of such information or for any infringement of patents or other rights of third parties that may result from its use. This document is not a commitment to develop, release, or deliver any Material (defined below), code, or functionality.

NVIDIA reserves the right to make corrections, modifications, enhancements, improvements, and any other changes to this document, at any time without notice.

Customer should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

NVIDIA products are sold subject to the NVIDIA standard terms and conditions of sale supplied at the time of order acknowledgement, unless otherwise agreed in an individual sales agreement signed by authorized representatives of NVIDIA and customer ("Terms of Sale"). NVIDIA hereby expressly objects to applying any customer general terms and conditions with regards to the purchase of the NVIDIA product referenced in this document. No contractual obligations are formed either directly or indirectly by this document.

NVIDIA products are not designed, authorized, or warranted to be suitable for use in medical, military, aircraft, space, or life support equipment, nor in applications where failure or malfunction of the NVIDIA product can reasonably be expected to result in personal injury, death, or property or environmental damage. NVIDIA accepts no liability for inclusion and/or use of NVIDIA products in such equipment or applications and therefore such inclusion and/or use is at customer's own risk.

NVIDIA makes no representation or warranty that products based on this document will be suitable for any specified use. Testing of all parameters of each product is not necessarily performed by NVIDIA. It is customer's sole responsibility to evaluate and determine the applicability of any information contained in this document, ensure the product is suitable and fit for the application planned by customer, and perform the necessary testing for the application in order to avoid a default of the application or the product. Weaknesses in customer's product designs may affect the quality and reliability of the NVIDIA product and may result in additional or different conditions and/or requirements beyond those contained in this document. NVIDIA accepts no liability related to any default, damage, costs, or problem which may be based on or attributable to: (i) the use of the NVIDIA product in any manner that is contrary to this document or (ii) customer product designs.

No license, either expressed or implied, is granted under any NVIDIA patent right, copyright, or other NVIDIA intellectual property right under this document. Information published by NVIDIA regarding third-party products or services does not constitute a license from NVIDIA to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property rights of the third party, or a license from NVIDIA under the patents or other intellectual property rights of NVIDIA.

Reproduction of information in this document is permissible only if approved in advance by NVIDIA in writing, reproduced without alteration and in full compliance with all applicable export laws and regulations, and accompanied by all associated conditions, limitations, and notices.

THIS DOCUMENT AND ALL NVIDIA DESIGN SPECIFICATIONS, REFERENCE BOARDS, FILES, DRAWINGS, DIAGNOSTICS, LISTS, AND OTHER DOCUMENTS (TOGETHER AND SEPARATELY, "MATERIALS") ARE BEING PROVIDED "AS IS." NVIDIA MAKES NO WARRANTIES, EXPRESSED, IMPLIED, STATUTORY, OR OTHERWISE WITH RESPECT TO THE MATERIALS, AND EXPRESSLY DISCLAIMS ALL IMPLIED WARRANTIES OF NONINFRINGEMENT, MERCHANTABILITY, AND FITNESS FOR A PARTICULAR PURPOSE. TO THE EXTENT NOT PROHIBITED BY LAW, IN NO EVENT WILL NVIDIA BE LIABLE FOR ANY DAMAGES, INCLUDING WITHOUT LIMITATION ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, PUNITIVE, OR CONSEQUENTIAL DAMAGES, HOWEVER CAUSED AND REGARDLESS OF THE THEORY OF LIABILITY, ARISING OUT OF ANY USE OF THIS DOCUMENT, EVEN IF NVIDIA HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. Notwithstanding any damages that customer might incur for any reason whatsoever, NVIDIA's aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms of Sale for the product.
