# Chapter 1. Introduction

DOCA Compress library provides an API to compress and decompress data using hardware acceleration, supporting both host and DPU memory regions.

The library provides an API for executing compress operations on DOCA buffers, where these buffers reside in either the DPU memory or host memory.

Using DOCA Compress, compress and decompress memory operations can be easily executed in an optimized, hardware-accelerated manner.

For BlueField-2 devices, this library supports:

- Compress operation using the deflate algorithm
- Decompress operation using the deflate algorithm

For BlueField-3 devices, this library supports:

- Decompress operation using the deflate algorithm
- Decompress operation using the LZ4 algorithm

This document is intended for software developers wishing to accelerate their application's compress memory operations.

# Chapter 2. Prerequisites

DOCA Compress-based applications can run either on the host machine or on the  $\mathsf{NVIDIA}^{\texttt{®}}$  BlueField  $^{\texttt{@}}$  DPU target.

# Chapter 3. Architecture

DOCA Compress relies heavily on the underlying DOCA core architecture for its operation, utilizing the existing memory map and buffer objects.

After initialization, a compress operation is requested by submitting a compress job on the relevant work queue. The DOCA Compress library then executes that operation asynchronously before posting a completion event on the work queue.

# Chapter 4. API

This chapter details the specific structures and operations related to the DOCA Compress library for general initialization, setup, and clean-up. See later sections for local and remote DOCA Compress operations.

The API for DOCA Compress consists of two DOCA Compress job structures.

The first one is struct doca compress deflate job for operations that use the deflate algorithm

```
struct doca compress deflate job {
                              /**< Common job data. */</pre>
struct doca_job base;
struct doca_buf *dst_buff;
job the
                                   * checksum calculated is of the
src buf.
                                   * If it is a decompress job the
checksum result
                                   * calculated is of the dst buf.
                                   * When the job processing will end,
the output chksum will
                                   * contain the CRC checksum result in
the lower 32bit
                                   * and the Adler checksum result in the
upper 32bit. */
```

The second one is struct doca compress 1z4 job for operations that use the LZ4 algorithm

```
struct doca_compress_lz4_job {
 struct doca_job base;
                                       /**< Common job data. */
struct doca_job base;
struct doca_buf *dst_buff;
struct doca_buf *dst_buff; /**< Destination data buffer. */
struct doca_buf const *src_buff; /**< Source data buffer.
                                              * The source buffer must be from local
memory.
                                              * Note: when using doca buf linked
list, the length of the
                                              * first data element in the source
buffer
                                              * must be at least 4B. */
                                            /**< Output checksum. If it is a compress
   uint64 t *output chksum;
 job the
                                              * checksum calculated is of the
 src buf.
                                              * If it is a decompress job the
 checksum result
                                              * calculated is of the dst buf.
                                              * When the job processing will end,
the output chksum will
```

```
* contain the CRC checksum result in
the lower 32bit
                                            and the Adler checksum result in the
upper 32bit. */
};
```

These structures are passed to the work queue to instruct the library on the source, destination, and checksum output.

The source and destination buffers should not overlap, while the data len field of the source doca buf defines the number of bytes to compress/decompress and the data field of the source doca buf defines the location in the source buffer to compress/ decompress from, to the destination buffer.

DOCA Compress library calculates the checksum and stores the result inside the output chksum field. The field length is 64 bits, where the lower 32 bits contain the CRC checksum result and the upper 32 bits contain the Adler checksum result.

As with other libraries, the compress job contains the standard doca job base field that must be set as follows:

For a deflate compress job:

```
/* Construct Compress job */
doca_job.type = DOCA COMPRESS DEFLATE JOB;
doca job.flags = DOCA JOB FLAGS NONE;
doca job.ctx = doca_compress_as_ctx(doca_compress_inst);
```

For a deflate decompress job:

```
/* Construct Deflate Decompress job */
doca job.type = DOCA DECOMPRESS DEFLATE JOB;
doca job.flags = DOCA JOB FLAGS NONE;
doca_job.ctx = doca_compress_as_ctx(doca_compress_inst);
```

For LZ4 decompress job:

```
/* Construct LZ4 Decompress job */
doca_job.type = DOCA DECOMPRESS LZ4 JOB;
doca job.flags = DOCA JOB FLAGS NONE;
doca job.ctx = doca compress as ctx(doca compress inst);
```

Compress job-specific fields should be set based on the required source and destination buffers. The user can provide output parameter so the library can store the checksum result in it or NULL.

```
compress job.base = doca job;
compress job.dst buff = dst doca buf;
compress job.src buff = src doca buf;
compress job.output chksum = output chksum;
```

To get the job result from the WorkQ, depending on the WorkQ working mode, the application can either periodically poll the work queue or wait for event on the work queue (via the doca workq progress retrieve API call).

When the retrieve call returns with a DOCA SUCCESS value (to indicate the work queues event is valid) you can then test that received event for success:

```
event.result.u64 == DOCA SUCCESS
```

### Compress operation:

### Decompress operation:

# Chapter 5. Local Memory **Programming Guide**

These sections discuss the usage of the DOCA Compress library in real-world situations. Most of this section utilizes code which is available through the DOCA Compress sample projects located under /samples/doca compress/ and application projects located under /applications/file compression.

When memory is local to your DOCA application (i.e., you can directly access the memory space of both source and destination buffers) this is referred to as a local compress/ decompress operation.

The following step-by-step guide goes through the various stages required to initialize, execute, and clean-up a local memory compress/decompress operation.

## 5.1. Initialization Process

The DOCA Compress API uses the DOCA core library to create the required objects (memory map, inventory, buffers, etc.) for the DOCA Compress library operations. This section runs through this process in a logical order. If you already have some of these operations in your DOCA application, you may skip or modify them as needed.

#### 5.1.1. **DOCA Device Open**

The first requirement is to open a DOCA device, normally your BlueField controller. You should iterate all DOCA devices (via doca devinfo list create) and select one using some criteria (e.g., PCIe address, etc). You can also use the function doca compress job get supported to check if the device is suitable for the compress job type you want to perform. After this, the device should be opened using doca dev open.

#### **Creating DOCA Core Objects** 5.1.2.

DOCA Compress requires several DOCA objects to be created. This includes the memory map (doca mmap create), buffer inventory (doca buf inventory create), and work queue (doca workg create). DOCA Compress also requires the actual DOCA Compress context to be created (doca compress create).

Once a DOCA Compress instance has been created, it can be used as a context using the doca ctx APIs this can be achieved by getting a context representation using doca compress as ctx().

## 5.1.3. Initializing DOCA Core Objects

In this phase of initialization, the core objects are ready to be set up and started.

### 5.1.3.1. Memory Map Initialization

Prior to starting the mmap (doca mmap start), make sure that you set the memory range correctly (via doca mmap set memrange). After starting mmap, add the DOCA device to the mmap (doca mmap dev add).

## 5.1.3.2. Buffer Inventory

This can be started using the doca buf inventory start call.

### 5.1.3.3. WorkQ Initialization

There are two options for the WorkQ working mode, the default polling mode or eventdriven mode.

To set the WorkQ to work in event-driven mode, use doca workq set event driven enable and then doca workq get event handle to get the event handle of the WorkQ so you can wait on events using epoll or other Linux wait for event interfaces.

## 5.1.3.4. DOCA Compress Context Initialization

The context created previously (via doca compress create()) and acquired using (doca compress as ctx()), can have the device added (doca ctx dev add), started (doca ctx start), and work queue added (doca ctx workq add). It is also possible to add multiple WorkQs to the same context as well.

### Constructing DOCA Buffers 514

Prior to building and submitting a compress operation, you must construct two DOCA buffers for the source and destination addresses (the addresses used must exist within the memory region registered with the memory map). The doca buf inventory buf by addr returns a doca buffer when provided with a memory address.

Finally, you must set the data address and length of the source DOCA buffer using the function doca buf set data. This field determines the data address and the data length perform de/compress on.

To know the maximum data len of the DOCA buffers that can be used to perform a de/compress operation on, users must call the function doca compress get max buffer size.

### **Compress Execution** 5.2.

The DOCA Compress operation is asynchronous in nature. Therefore, you must enqueue the operation and poll for completion later.

## 5.2.1. Constructing and Executing DOCA **Compress Operation**

To begin the compress operation, you must enqueue a compress job on the previously created work queue object. This involves creating the DOCA Compress job (struct doca compress job) that is a composite of specific compress fields.

Within the compress job structure, the context field must point to your DOCA Compress context, and the type field must be set to:

- DOCA COMPRESS DEFLATE JOB for a deflate compress operation
- DOCA DECOMPRESS DEFLATE JOB for a deflate decompress operation
- DOCA DECOMPRESS LZ4 JOB for LZ4 decompress operation

The DOCA Compress specific elements of the job point to your DOCA buffers for the source and destination and to a checksum field that uses to store the checksum result from the hardware.

Note that if it is a compress job, the checksum result calculated is of the source buffer. If it is a decompress job, the checksum result calculated is of the destination buffer.

Finally, the doca workg submit API call is used to submit the compress operation to the hardware.

## 5.2.2. Waiting for Completion

According to the WorkQ mode, you can detect when the compress operation has completed (via doca workq progress retrieve):

- WorkQ operates in polling mode periodically poll the work queue until the API call indicates that a valid event has been received
- WorkQ operates in event mode while doca workq progress retrieve does not return a success result, perform the following loop:
  - 1. Arm the WorkQ doca workq event handle arm.
  - 2. Wait for an event using the event handle (e.g., using epoll wait ()).
  - 3. Once the thread wakes up, call doca workq event handle clear.

Regardless of the operating mode, you should be able to detect the success of the compress operation if the event.result.u64 field is equal to DOCA SUCCESS. It should be noted that other work queue operations (i.e., non-compress operations) present their events differently. Refer to their respective guides for more information.

If there is already data inside the destination buffer, the DOCA Compress library appends the compress operation result after the existing data. Otherwise, the DOCA Compress library stores the new data in the data address of the destination buffer. Either way the library keeps the data address unchanged and increases the data len field of the destination buffer by the number of bytes produced by the de/compress operation.

To clean up the doca buffers, you should deference them using the doca buf refcount rm call. This call should be made on all buffers when you are finished with them (regardless of whether the operation is successful or not).

## 5.2.3. Clean Up

The main cleanup process is to remove the worker queue from the context (doca ctx workg rm), stop the context itself (doca ctx stop), remove the device from the context (doca ctx dev rm), and remove the device from the memory map (doca mmap dev rm).

The final destruction of the objects can now occur. This can happen in any order, but destruction must occur on the work queue (doca workg destroy), compress context (doca compress destroy), buf inventory (doca buf inventory destroy), mmap (doca mmap destroy), and device closure (doca dev close).

# Chapter 6. Remote Memory **Programming Guide**

This section covers the creation of a remote memory DOCA Compress operation. This operation allows memory from the host, accessible by DOCA Compress on the DPU, to be used as a source or destination.

## 6.1. Sender

The sender holds the source memory to perform the compress operation on and sends it to the DPU. The developer decides the method of how the source memory address is transmitted to the DPU. For example, it can be a socket that is connected from a "local" host sender to a "remote" BlueField DPU receiver. The address is passed using this method.

The sender application should open the device, as per a normal local memory operation, but initialize only a memory map (doca mmap create, doca mmap start, doca mmap dev add). It should then populate the mmap with exactly memory region (doca mmap set memrange) and call a special mmap function (doca mmap export).

This function generates a descriptor object that can be transmitted to the DPU. The information in the descriptor object refers to the exported "remote" host memory (from the perspective of the receiver).

### 6.2. Receiver

For reception, the standard initiation described for the local memory process should be followed.

Prior to constructing the DOCA buffer (via doca buf inventory buf by addr) to represent the host memory, you should call the special mmap function that retrieves the remote mmap from the host (doca mmap create from export). The DOCA buffer can then be created using this remote mmap and used as source/destination buffer in the DOCA Compress job structures.

Note: When using an LZ4 operation the source buffer must be from local memory.

All other aspects of the application (executing, waiting on results, and cleanup) should be the same as the process described for local memory operations.

# Chapter 7. DOCA Compress SG Support

DOCA compress library supports scatter-gather (SG) DOCA buffers. You can use a doca buf with a linked list extension as the source buffer in the doca compress job. The library then compresses/decompresses all the content of the DOCA buffers to a single destination buffer.

Note: When using SG for a LZ4 decompress operation, the first data element in the source buffer must be at least 4B.

# Chapter 8. DOCA Compress Samples

This document describes compress samples based on the DOCA Compress library. These samples illustrate how to use the DOCA Compress API to compress and decompress files.

## Running the Sample

- 1. Refer to the following documents:
  - NVIDIA DOCA Installation Guide for Linux for details on how to install BlueFieldrelated software.
  - NVIDIA DOCA Troubleshooting Guide for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
- 2. To build a given sample:

```
cd /opt/mellanox/doca/samples/doca_compress/<sample_name>
meson build
ninja -C build
```

Note: The binary doca <sample name> is created under ./build/.

3. Sample (e.g., doca compress deflate) usage:

```
Usage: doca compress deflate [DOCA Flags] [Program Flags]
DOCA Flags:
 -n, --help Print a help synopsis
-v, --version Print program version information
-1, --log-level Set the log level
                                     Set the log level for the program <CRITICAL=20,
ERROR=30, WARNING=40, INFO=50, DEBUG=60>
Program Flags:
                    PCI device address input file to compress/decompress
  -p, --pci-addr
-f, --file
  -m, --mode
                                    mode - {compress, decompress}
  -o, --output
                                     output file
```

For additional information per sample, use the -h option:

```
./build/doca <sample name> -h
```

# 8.2. Samples

#### Compress Deflate 8.2.1.

This sample illustrates how to use DOCA Compress library to compress and decompress a file.

The sample logic includes:

- 1. Locating a DOCA device.
- 2. Initializing the required DOCA core structures.
- 3. Populating DOCA memory map with two relevant buffers; one for the source data and one for the result.
- 4. Allocating elements in DOCA buffer inventory for each buffer.
- 5. Initializing DOCA Compress job object.
- 6. Submitting a compress or decompress job into the work gueue.
- 7. Retrieving the job from the queue once it is done.
- 8. Writing the result into an output file, out.txt.
- 9. Destroying all compress and DOCA core structures.
