DOCA DevEmu PCI
Table of contents

DOCA DevEmu PCI Generic 17
Introduction

DOCA DevEmu PCI is part of the DOCA Device Emulation subsystem. It provides low-level software APIs that allow management of an emulated PCIe device using the emulation capability of NVIDIA® BlueField® networking platforms.

It is a common layer for all PCIe emulation modules, such as DOCA DevEmu PCIe Generic Emulation, and DOCA DevEmu Virtio subsystem emulation.

Prerequisites

This library follows the architecture of a DOCA Core Context. It is recommended read the following sections beforehand:

- DOCA Core Execution Model
- DOCA Core Device
- DOCA Core Memory Subsystem

Generic device emulation is part of DOCA device emulation. It is recommended to read the following guides beforehand:

- DOCA Device Emulation

Environment

DOCA DevEmu PCI Emulation is supported only on the BlueField target. The BlueField must meet the following requirements:

- DOCA version 2.7.0 or greater
- BlueField-3 firmware 32.41.1000 or higher

1. Info

Please refer to the DOCA Backward Compatibility Policy.

The library must be run with root privileges.

Perform the following:

1. Configure the BlueField to work in DPU mode as described in *NVIDIA BlueField Modes of Operation*.

2. Enable the PCIe switch emulation capability needed for hot plugging emulated PCIe devices. This can be done by running the following command on the host or BlueField:

   ```
   host/bf> sudo mlxconfig -d /dev/mst/mt41692_pciconf0 s PCI_SWITCH_EMULATION_ENABLE=1
   ```

3. Perform a BlueField system-level reset for the mlxconfig settings to take effect.

To support hot-plug feature, the host must have the following boot parameters:

- Intel CPU:

  ```
  intel_iommu=on iommu=pt pci=realloc
  ```

- AMD CPU:

  ```
  iommu=pt pci=realloc
  ```

This can be done using the following steps:
1. Add the boot parameters:

```plaintext
host> sudo nano /etc/default/grub
Find the variable
GRUB_CMDLINE_LINUX_DEFAULT="<existing-params>"
Add the params at the end
GRUB_CMDLINE_LINUX_DEFAULT="<existing-params> intel_iommu=on iommu=pt pci=realloc"
```

2. Update configuration.

   - For Ubuntu:
     ```plaintext
     host> update-grub
     ```
   
   - For RHEL:
     ```plaintext
     host> grub2-mkconfig -o /boot/grub2/grub.cfg
     ```

3. Perform warm boot.

4. Confirm that the parameters are in effect:

```plaintext
host> cat /proc/cmdline
<existing-params> intel_iommu=on iommu=pt pci=realloc
```
Architecture

The DOCA DevEmu PCI library provides 2 main software abstractions, the PCIe type, and the PCIe device. The PCIe type represents the configurations of the emulated device, while the PCIe device represents an instance of an emulated device. Furthermore, any PCIe device instance must be associated with a single PCIe type, while PCIe type can be associated with many PCIe devices.

Pre Defined PCI Type vs. Generic PCI Type

A PCIe type object can be acquired in 2 different ways:

- Acquire a pre-defined type, using emulation libraries of existing protocols such as DOCA DevEmu Virtio FS library
- Create from scratch using the DOCA DevEmu Generic library

In case of pre-defined type, the configurability of the type is limited.

PCIe Type Name

As part of the DOCA PCIe emulation, every type has a name assigned to it. This property is not part of the PCIe specification, but rather it is a mechanism in DOCA that uniquely identifies the PCIe type.

There cannot be 2 different PCIe types with the same name, even across different processes, unless the type in the second process is configured in identical manner to the first one. Furthermore, attempting to configure the second type with same name but with slight configuration difference will fail.

Create Emulated Device

After configuring the desired DOCA DevEmu PCIe type, it is possible to create an emulated device based on the configured type using doca_devemu_pci_dev_create_rep. This sequential process ensures that the DOCA DevEmu PCIe device is created with the
specified parameters and configuration defined by the PCIe type object. Furthermore, it is possible to destroy the emulated device using `doca_devemu_pci_dev_destroy_rep`.

The created device representor starts in "power_off" state and is not visible to the host until hot-plug sequence is issued by the user, see Hot-plug Emulated Device. The device can then be destroyed only while in "power_off" state.

![Info]

The created emulated device may outlive the application that created it, see Objects Lifecycle and Persistency.

**Hot-plug Emulated Device**

Hot-plugging refers to the process of emulating the physical attachment of a PCIe device to the host PCIe subsystem after the system has been powered on and initialized. Note that some operating systems require additional settings to enable the process of hot-plugging a PCIe device. For supported systems, this feature proves particularly advantageous for systems that need to remain operational at all times while expanding their hardware resources, such as additional storage and networking capabilities. DOCA DevEmu PCI provides software APIs that allow users to emulate this process in an asynchronous manner.
When creating a PCIe device object, if it starts in "power off" state, then the device is not yet visible to the host. It is possible then, from the BlueField, to hot-plug the device. This starts an async process of the device getting hot-plugged towards the host. Once the process completes, the emulated device transitions to "power on" and becomes visible to the host. Usually at this stage, the emulated device receives its BDF address. The hot-unplug process works in similar async manner.
Using DOCA API, the BlueField Arm can register to any changes to the hot-plug state of each emulated device using `doca_devemu_pci_dev_event_hotplug_state_change_register`.

**Emulated Device Discovery**

The emulated device is represented as a `doca_devinfo_rep`. It is possible to iterate through all the emulated devices as explained in [DOCA Core Representor Discovery](#).

There are 2 ways of filtering the list of emulated devices:

- Get all emulated devices – use `DOCA_DEVINFO_REP_FILTER_EMULATED` as the filter argument in `doca_devinfo_rep_create_list`
- Get all emulated devices that belong to a certain type – `doca_devemu_pci_type_create_rep_list`

**Objects Lifecycle and Persistency**

This section creates distinction between firmware resources and software resources:

- Firmware resources persist until the next power cycle, and can be accessible from different processes on the BlueField Arm. Such resources are not cleared once the application exits.
- Software resources are representations of firmware resources, and are only relevant for the same thread

Using this terminology, it is possible to describe the objects as follows:

- The PCIe type object `doca_devemu_pci_type` represents a PCIe type firmware resource. The resource persists if any of the following apply:
  - There is at least 1 process holding reference to the PCIe type
  - There is at least 1 PCIe device firmware resource belonging to this type
The emulated device representor, `doca_devinfo_rep`, represents an emulated PCIe function firmware resource:

- `doca_devemu_pci_dev_create_rep` can be used to create such firmware resource
- To destroy the firmware resource, `doca_devemu_pci_dev_destroy_rep` can be used
- For static functions, the representor resource persists until configured otherwise in NVCONFIG
- To find existing PCIe device firmware resources, use `doca_devemu_pci_type_create_rep_list`

**Function Level Reset**

The created emulated devices support PCIe function level reset (FLR).

Using DOCA API, the BlueField Arm can register to FLR event using `doca_devemu_pci_dev_event_flr_register`. Once the driver requests FLR, this event is triggered, calling the user provided callback.

Once FLR is detected, it is expected for the BlueField Arm to do the following:

- Destroy all resources related to the PCIe device. For information on such resources, refer to the guide of concrete PCIe type (generic/virtiofs).
- Stop the PCIe device
- Start the PCIe device again

**Device Support**

DOCA PCIe Device emulation requires a device to operate. For picking a device, see DOCA Core Device Discovery.

The device emulation library is only supported for BlueField-3.
As device capabilities may change in the future (see Capability Checking), it is recommended that users choose a device using the following method:

- `doca_devemu_pci_cap_type_is_hotplug_supported` – for create and hot-plug support
- `doca_devemu_pci_cap_type_is_mgmt_supported` – for device discovery only

**PCle Device**

**Configuration Phase**

To start using the DOCA DevEmu PCI Device, users must first go through a configuration phase as described in DOCA Core Context Configuration Phase.

This section describes how to configure and start the context to allow retrieval of events.

**Configurations**

The context can be configured to match the application use case.

To find if a configuration is supported or what its min/max value is, refer to Device Support.

**Mandatory Configurations**

All mandatory configurations are provided during the creation of the PCIe device.

These configurations are as follows:

- A DOCA DevEmu PCIe type object
- A DOCA Device Representor, representing an emulated function with the same type as the provided PCIe object type
- A DOCA Progress Engine object

**Optional Configurations**

These configurations are optional. If not set, then a default value is used:
• Registering to events as described in the "Events" section. By default, the user does not receive events.

## Execution Phase

This section describes execution on CPU using [DOCA Core Progress Engine](#).

### Events

The DOCA DevEmu PCI device exposes asynchronous events to notify about sudden changes according to DOCA Core architecture.

Common events are described in [DOCA Core Event](#).

### Hotplug State Change

The hotplug state change event allows users to receive notifications whenever the hotplug state of the emulated device changes. See section "Hot-plug Emulated Device".

### Event Configuration

<table>
<thead>
<tr>
<th>Description</th>
<th>API to Set the Configuration</th>
<th>API to Query Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register to the event</td>
<td>doca_devemu_pci_dev_event_hotplug_state_change_register</td>
<td>doca_devemu_pci_cap_type_is_hotplug_supported</td>
</tr>
</tbody>
</table>

### Event Trigger Condition

The event is triggered anytime an asynchronous transition happens as follows:

- DOCA_DEVEMU_PCI_HP_STATE_PLUG_IN_PROGRESS  DOCA_DEVEMU_PCI_HP_STATE_POWER_ON
- DOCA_DEVEMU_PCI_HP_STATE_UNPLUG_IN_PROGRESS  DOCA_DEVEMU_PCI_HP_STATE_POWER_OFF
- `DOCA_DEVEMU_PCI_HP_STATE_POWER_ON`  
  `DOCA_DEVEMU_PCI_HP_STATE_UNPLUG_IN_PROGRESS`  
  (when initiated by the host)

Any transition initiated by user is not triggered (e.g., calling hotplug to transition from `POWER_OFF` to `PLUG_IN_PROGRESS`).

The following APIs can be used to initiate hotplug or hot-unplug transition processes:

- `doca_devemu_pci_dev_hotplug`
- `doca_devemu_pci_dev_hotunplug`

**Event Output**

Common output as described in [DOCA Core Event](#).

Additionally, the internal cached hotplug state is updated and can be fetched using `doca_devemu_pci_dev_get_hotplug_state`.

**Event Handling**

Once the event is triggered, it means that the hotplug state has changed. The application is expected to do the following:

- Retrieve the new hotplug state using `doca_devemu_pci_dev_get_hotplug_state`

**Function Level Reset**

The FLR event allows users to receive notifications whenever the host initiates an FLR flow. See section "**Function Level Reset**".

**Event Configuration**
<table>
<thead>
<tr>
<th>Description</th>
<th>API to Set the Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register to the event</td>
<td><code>doca_devemu_pci_dev_event_flr_register</code></td>
</tr>
</tbody>
</table>

**Event Trigger Condition**

The event is triggered anytime the host driver initiates an FLR flow. See section "Function Level Reset".

**Event Output**

Common output as described in DOCA Core Event.

Additionally, the internal cached FLR indicator is updated and can be fetched using `doca_devemu_pci_dev_is_flr`.

**Event Handling**

Once the event is triggered, it means that the host driver has initiated the FLR flow.

The user must handle the FLR flow by doing the following:

1. Flush all the outstanding requests back to the associated resource
2. Release all the PCIe device resources dynamically created after device start
3. Stop the PCIe device – `doca_ctx_stop`
4. Start the PCIe device again – `doca_ctx_start`
   - Call `doca_pe_progress` repeatedly until the PCIe device transitions to "running" state

For more information on starting the PCIe device again, refer to section "State Machine".
State Machine

The DOCA DevEmu PCI device object follows the context state machine as described in DOCA Core Context State Machine.

The following section describes how to transition to any state and what is allowed in each state.

Idle

In this state, it is expected that application either:

- Destroys the context
- Starts the context

Allowed operations:

- Configuring the context according to section "Configurations"
- Starting the context

It is possible to reach this state as follows:

<table>
<thead>
<tr>
<th>Previous State</th>
<th>Transition Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Create the context</td>
</tr>
<tr>
<td>Running</td>
<td>Call stop after making sure all resources have been destroyed</td>
</tr>
<tr>
<td>Stopping</td>
<td>Call progress until all resources have been destroyed</td>
</tr>
</tbody>
</table>

Starting

In this state, it is expected that application:
- Calls progress to allow transition to next state
- Keeps context in this state until FLR flow is complete

It is possible to reach this state as follows:

<table>
<thead>
<tr>
<th>Previous State</th>
<th>Transition Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle</td>
<td>Call start after receiving FLR event (i.e., while FLR is in progress)</td>
</tr>
</tbody>
</table>

**Running**

In this state, it is expected that application:

- Calls progress to receive events
- Creates/destroys PCIe device resources

It is possible to reach this state as follows:

<table>
<thead>
<tr>
<th>Previous State</th>
<th>Transition Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idle</td>
<td>Call start after configuration</td>
</tr>
<tr>
<td>Starting</td>
<td>Call progress until FLR flow is completed</td>
</tr>
</tbody>
</table>

**Stopping**

In this state, it is expected that application:

- Destroys all emulated device resources as described in section "Function Level Reset".

Allowed operations:

- Destroying PCIe device resources

It is possible to reach this state as follows:
<table>
<thead>
<tr>
<th>Previous State</th>
<th>Transition Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Running</td>
<td>Call stop without freeing emulated device resources</td>
</tr>
</tbody>
</table>
DOCA DevEmu PCI Generic

Note

This library is supported at alpha level; backward compatibility is not guaranteed.

This guide provides instructions on building and developing applications that require emulation of a generic PCIe device.

Introduction

DOCA DevEmu PCI Generic is part of the DOCA Device Emulation subsystem. It provides low-level software APIs that allow creation of a custom PCIe device using the emulation capability of NVIDIA® BlueField®.

For example, it enables emulating an NVMe device by creating a generic emulated device, configuring its capabilities and BAR to be compliant with the NVMe spec, and operating it from the DPU as necessary.

Prerequisites

This library follows the architecture of a DOCA Core Context. It is recommended read the following sections beforehand:

- [DOCA Core Execution Model](#)
- [DOCA Core Device](#)
- [DOCA Core Memory Subsystem](#)

Generic device emulation is part of DOCA PCIe device emulation. It is recommended to read the following guides beforehand:
Environment

DOCA DevEmu PCI Generic Emulation is supported only on the BlueField target. The BlueField must meet the following requirements:

- DOCA version 2.7.0 or greater
- BlueField-3 firmware 32.41.1000 or higher

Library must be run with root privileges.

Please refer to DOCA DevEmu PCI Environment, for further necessary configurations.

Architecture

DOCA DevEmu PCI Generic allows the creation of a generic PCI type. The PCI Type is part of the DOCA DevEmu PCI library. It is the component responsible for configuring the capabilities and bar layout of emulated devices.

The PCI Type can be considered as the template for creating emulated devices. Such that the user first configures a type, and then they can use it to create multiple emulated devices that have the same configuration.

For a more concrete example, consider that you would like to emulate an NVMe device, then you would create a type and configure its capabilities and BAR to be compliant with the NVMe spec, after that you can use the same type, to generate multiple NVMe emulated devices.
# PCIe Configuration Space

The PCIe configuration space is 256 bytes long and has a header that is 64 bytes long. Each field can be referred to as a register (e.g., device ID).

Every PCIe device is required to implement the PCIe configuration space as defined in the PCIe specification.

The host can then read and/or write to registers in the PCIe configuration space. This allows the PCIe driver and the BIOS to interact with the device and perform the required setup.

It is possible to configure registers in the PCIe configuration space header as shown in the following diagram:

<table>
<thead>
<tr>
<th>31-24</th>
<th>23-16</th>
<th>15-8</th>
<th>7-0</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

**BAR**

While the PCIe configuration space can be used to interact with the PCIe device, it is not enough to implement the functionality that is targeted by the device. Rather, it is only relevant for the PCIe layer.

To enable protocol-specific functionality, the device configures additional memory regions referred to as base address registers (BARs) that can be used by the host to interact with the device. Different from the PCIe configuration space, BARs are defined by the device and interactions with them is device-specific. For example, the PCIe driver interacts with an NVMe device's PCIe configuration space according to the PCIe spec, while the NVMe driver interacts with the BAR regions according to the NVMe spec.
Any read/write requests on the BAR are typically routed to the hardware, but in case of an emulated device, the requests are routed to the software.

The DOCA DevEmu PCI type library provides APIs that allow software to pick the mechanism used for routing the requests to software, while taking into consideration common design patterns utilized in existing devices.

Each PCIe device can have up to 6 BARs with varying properties. During the PCIe bus enumeration process, the PCIe device must be able to advertise information about the layout of each BAR. Based on the advertised information, the BIOS/OS then allocates a memory region for each BAR and assigns the address to the relevant BAR in the PCIe configuration space header. The driver can then use the assigned memory address to perform reads/writes to the BAR.

**BAR Layout**

The PCIe device must be able to provide information with regards to each BAR's layout.

The layout can be split into 2 types, each with their own properties as detailed in the following subsections.

**I/O Mapped**

According to the PCIe specification, the following represents the I/O mapped BAR:
Additionally, the BAR register is responsible for advertising the requested size during enumeration.

Info

The size must be a power of 2.

Users can use the following API to set a BAR as I/O mapped:

```
doca_devemu_pci_type_set_io_bar_conf(struct doca_devemu_pci_type *pci_type, uint8_t id, uint8_t log_sz)
```

- `id` – the BAR ID
- `log_sz` – the log of the BAR size

Memory Mapped

According to the PCIe specification, the following represents the memory mapped BAR:

Additionally, the BAR register is responsible for advertising the requested size during enumeration.

Info
The memory mapped BAR allows a 64-bit address to be assigned. To achieve this, users must specify the bar Memory Type as 64-bit, and then set the next BAR's (BAR ID + 1) size to be 0.

Setting the pre-fetchable bit indicates that reads to the BAR have no side-effects.

Users can use the following API to set a BAR as memory mapped:

```c
void doca_devemu_pci_type_set_memory_bar_conf(struct doca_devemu_pci_type *pci_type, uint8_t id, uint8_t log_sz, enum doca_devemu_pci_bar_mem_type memory_type, uint8_t prefetchable)
```

- **id** – the BAR ID
- **log_sz** – the log of the BAR size. If set to 0, then the size is considered as 0 (instead of 1).
- **memory_type** – specifies the memory type of the BAR. If set to 64-bit, then the next BAR must have log_sz set to 0.
- **prefetchable** – indicates whether the BAR memory is pre-fetchable or not (a value of 1 or 0 respectively)

**BAR Regions**

BAR regions refer to memory regions that make up a BAR layout. This is not something that is part of the PCIe specification, rather it is a DOCA concept that allows the user to customize behavior of the BAR when interacted with by the host.

The BAR region defines the behavior when the host performs a read/write to an address within the BAR, such that every address falls in some memory region as defined by the user.
Common Configuration

All BAR regions have these configurations in common:

- **id** – the BAR ID that the region is part of
- **start_addr** – the start address of the region within the BAR layout relative to the BAR. 0 indicates the start of the BAR layout.
- **size** – the size of the BAR region

Currently, there are 4 BAR region types, defining different behavior:

- Stateful
- DB by offset
- DB by data
- MSIX table
- MSIX PBA

Generic Control Path (Stateful BAR Region)
Stateful region can be used as a shared memory, such that the contents are maintained in firmware. A read from the driver returns the latest value, while a write updates the value and triggers an event to software running on the DPU.

This can be useful for communication between the driver and the device, during the control path (e.g., exposing capabilities, initialization).

**Info**

Some limitations apply, please see [Limitations section](#).

**Driver Read**

A read from the driver returns the latest value written to the region, whether written by the host or by the driver itself.

**Driver Write**

A write from the driver updates the value at the written address and notifies software running on the Arm that a write has occurred. The notification on the Arm arrives as an asynchronous event (see `doca_devemu_pci_dev_event_bar_stateful_region_driver_write`).
The DPU can read the values of the stateful region using `doca_devemu_pci_dev_query_bar_stateful_region_values`. This returns the latest snapshot of the stateful region values. It can be particularly useful to find what was written by the driver after the "stateful region driver write event" occurs.

### DPU Write

The DPU can write the values of the stateful region using `doca_devemu_pci_dev_modify_bar_stateful_region_values`. This updates the values such that subsequent reads from the driver or the DPU returns these values.

### Default Values

The event that arrives to Arm software is asynchronous such that it may arrive after the driver has completed the write.
The DPU is able to set default values to the stateful region. Default values come in 2 layers:

- Type default values – these values are set for all devices that have the same type. This can be set only if no device currently exists.

- Device default values – these values are set for a specific device and take affect on the next FLR cycle or the next hotplug of the device

A read of the stateful region follows the following hierarchy:

1. Return the latest value as written by the host or driver (whichever was done last).

2. Return the device default values.

3. Return the type default values.

4. Return 0.
Generic Data Path (DB BAR Region)

Doorbell (DB) regions can be used to implement a consumer-producer queue between the driver and the DPU, such that a write from the driver would trigger an event on the DPU through DPA, allowing it to fetch the written value. This can be useful for communication between the driver and the device, during the data path allowing IO processing.

While DBs are not part of the PCIe specification, it is a widely used mechanism by vendors (e.g., RDMA QP, NVMe SQ, virtio VQ, etc).

The same DB region can be used to manage multiple DBs, such that each DB can be used to implement a queue.

The DPU software can utilize DB resources individually:

- Each DB resource has a unique zero-based index referred to as DB ID
- DB resource can be managed (create/destroy/modify/query) individually
- Each DB resource has a separate notification mechanism. That is, the notification on DPU is triggered for each DB separately.

Driver Write
The DB usually consists of a numeric value (e.g., \texttt{uint32_t}) representing the consumer/producer index of the queue.

When the driver writes to the DB region, the related DB resource gets updated with the written value, and a notification is sent to the DPU.

When driver writes to the DB BAR region it must adhere to the following:

- The size of the write must match the size of the DB value (e.g., \texttt{uint32_t})
- The offset within the region must be aligned to the DB stride size or the DB size

The flow would look something as the following:

- Driver performs a write of the DB value at some offset within the DB BAR region
- DPU calculates the DB ID that the write is intended for. Depending on the region type:
  - DB by offset – DPU calculates the DB ID based on the write offset relative to the DB BAR region
  - DB by data – DPU parses the written DB value and extracts the DB ID from it
- DPU updates the DB resource with the matching DB ID to the value written by the driver
- DPU sends a notification to the DPA application, informing it that the value of DB with DB ID has been updated by the driver

**Driver Read**

The driver should not attempt to read from the DB region. Doing so results in anomalous behavior.

**BlueField Write**
The BlueField can update the value of each DB resource individually using `doca_devemu_pci_db_modify_value`. This produces similar side effects as though the driver updated the value using a write to the DB region.

**BlueField Read**

The BlueField can read the value of each DB resource individually using one of the following methods:

- Read the value from the BlueField Arm using `doca_devemu_pci_db_query_value`
- Read the value from the DPA using `doca_dpa_dev_devemu_pci_db_get_value`

The first option is a time consuming operation and is only recommended for the control path. In the data path, it is recommended to use the second option only.

**DB by Offset**

The API `doca_devemu_pci_type_set_bar_db_region_by_offset_conf` can be used to set up DB by offset region. When the driver writes a DB value using this region, the DPU receives a notification for the relevant DB resource, based on the write offset, such that the DB ID is calculated as follows: \( db_id = \frac{\text{write_offset}}{\text{db_stride_size}} \).

⚠️ **Warning**

The API `doca_devemu_pci_type_set_bar_db_region_by_offset_conf` can be used to set up DB by offset region. When the driver writes a DB value using this region, the DPU receives a notification for the relevant DB resource, based on the write offset, such that the DB ID is calculated as follows: \( db_id = \frac{\text{write_offset}}{\text{db_stride_size}} \).
The API `doca_devemu_pci_type_set_bar_db_region_by_data_conf` can be used to set up DB by data region. When the driver writes a DB value using this region, the DPU receives a notification for the relevant DB resource based on the written DB value, such that there is no relation between the write offset and the DB triggered. This DB region assumes that the DB ID is embedded within the DB value written by the driver. When setting up this region, the user must specify where the Most Significant Byte (MSB) and Least Significant Byte (LSB) of the DB ID are embedded in the DB value.

The DPU follows these steps to extract the DB ID from the DB value:

- Driver writes the DB value
- BlueField extracts the bytes between MSB and LSB
- DPU compares MSB index with LSB index
  - If MSB index greater than LSB index: The extracted value is interpreted as Little Endian
If LSB index greater than MSB index: The extracted value is interpreted as Big Endian

Example:

DB size is 4 bytes, LSB is 1, and MSB is 3.

- Driver writes value 0xCCDDEEFF to DB region at index 0 in Little Endian
  - The relevant bytes, are the following: [1]=EE [2]=DD [3]=CC
  - Since MSB (3) is greater than LSB (1), the value is interpreted as Little Endian: \(db_{id} = 0xCCDDEE\)

**MSI-X Capability (MSI-X BAR Region)**

Message signaled interrupts extended (MSI-X) is commonly used by PCIe devices to send interrupts over the PCIe bus to the host driver. DOCA APIs allow users to expose the MSI-X capability as per the PCIe specification, and to later use it to send interrupts to the host driver.

To configure it, users must provide the following:

- The number of MSI-X vectors which can be done using `doca_devemu_pci_type_set_num_msix`
- Define an MSI-X table
- Define an MSI-X PBA

**MSI-X Table BAR Region**

As per the PCIe specification, to expose the MSI-X capability, the device must designate a memory region within its BAR as an MSI-X table region. In DOCA, this can be done using `doca_devemu_pci_type_set_bar_msix_table_region_conf`. 
**MSI-X PBA BAR Region**

As per the PCIe specification, to expose the MSI-X capability, the device must designate a memory region within its BAR as an MSI-X pending bit array (PBA) region. In DOCA, this can be done using `doca_devemu_pci_type_set_bar_msix_pba_region_conf`.

**Raising MSI-X From DPU**

It is possible to raise an MSI-X for each vector individually. This can be done only using the DPA API `doca_dpa_dev_devemu_pci_msix_raise`.

**DMA Memory**

Some operations require accessing memory which is set up by the host driver. DOCA's device emulation APIs allow users to access such I/O memory using the DOCA mmap (see [DOCA Core Memory Subsystem](#)).

After starting the PCIe device, it is possible to acquire an mmap that references the host memory using `doca_devemu_pci_mmap_create`. After creating this mmap, it is possible to configure it by providing:

- Access permissions
- Host memory range
- DOCA devices that can access the memory

The mmap can then be used to create buffers that reference memory on the host. The buffers' addresses would not be locally accessible (i.e., CPU cannot dereference the address), instead the addresses would be I/O addresses as defined by the host driver.

The buffers created from the mmap can then be used with other DOCA libraries and accept a `doca_buf` as an input. This includes:

- **DOCA DMA**
- DOCA RDMA
- DOCA Ethernet
- DOCA AES-GCM

Function Level Reset

FLR can be handled as described in DOCA DevEmu PCI FLR. Additionally, users must ensure that the following resources are destroyed before stopping the PCIe device:

- Doorbells created using `doca_devemu_pci_db_create_on_dpa`
- MSI-X vectors created using `doca_devemu_pci_msix_create_on_dpa`
- Memory maps created using `doca_devemu_pci_mmap_create`

Limitations

Based on explanation in "Driver Write", user can assume that DOCA DevEmu PCI Generic supports creating emulated PCI devices with the limitation that when a driver writes to a register, the value is immediately available for subsequent reads from the same register. However, this immediate availability does not ensure that any required internal actions triggered by the write have been completed. It is recommended to rely on specific different register values to confirm completion of the write action. For instance, when implementing a write-to-clear operation, e.g. writing 1 to register A to clear register B, it is advisable to poll register B until it indicates the desired state. This approach ensures that the write action has been successfully executed. If a device specification requires certain actions to be completed before exposing written values for subsequent reads, such a device cannot be emulated using the DOCA DevEmu PCI generic framework.

Device Support

DOCA PCI Device emulation requires a device to operate. For information on picking a device, see DOCA DevEmu PCI Device Support.
Some devices can allow different capabilities as follows:

- The maximum number of emulated devices
- The maximum number of different PCIe types
- The maximum number of BARs
- The maximum BAR size
- The maximum number of doorbells
- The maximum number of MSI-X vectors
- For each BAR region type there are capabilities for:
  - Whether the region is supported
  - The maximum number of regions with this type
  - The start address alignment of the region
  - The size alignment of the region
  - The min/max size of the region

**Tip**

As the list of capabilities can be long, it is recommended to use the NVIDIA DOCA Capabilities Print Tool to get an overview of all the available capabilities.

Run the tool as root user as follows:

```bash
$ sudo /opt/mellanox/doca/tools/doca_caps -p <pci-address> -b devemu_pci
Example output: PCI: 0000:03:00.0
    devemu_pci
        max_hotplug_devices  15
        max_pci_types  2
        type_log_min_bar_size  12
```

Configurations

This section describes the configurations of the DOCA DevEmu PCI Type object, that can be provided before start.

To find if a configuration is supported or what its min/max value is, refer to Device Support.

Mandatory Configurations

The following are mandatory configurations and must be provided before starting the PCI type:

- A DOCA device that is an emulation manager or hotplug manager. See Device Support.

Optional Configurations

The following configurations are optional:

- The PCIe device ID
- The PCIe vendor ID
- The PCIe subsystem ID
- The PCIe subsystem vendor ID
- The PCIe revision ID
- The PCIe class code
- The number of MSI-X vectors for MSI-X capability
- One or more memory mapped BARs
- One or more I/O mapped BARs
- One or more DB region
- An MSI-X table and PBA regions
- One or more stateful regions

ℹ️ **Info**

If these configurations are not set then a default value is used.

**PCI Device**

**Configuration Phase**

This section describes additional configuration options, on top of the ones already described in [DOCA DevEmu PCI Device Configuration Phase](#).

**Configurations**

The context can be configured to match the application's use case.

To find if a configuration is supported or what its min/max value is, refer to [Device Support](#).

**Optional Configurations**

The following configurations are optional:

- Setting the stateful regions' default values – If not set, then the type default values are used. See [stateful region default values](#) for more.
Execution Phase

This section describes additional events, on top of the ones already described in DOCA DevEmu PCI Device Events.

Events

DOCA DevEmu PCI Device exposes asynchronous events to notify about changes that happen suddenly according to the DOCA Core architecture.

Common events are described in DOCA Core Event.

BAR Stateful Region Driver Write

The stateful region driver write event allows you to receive notifications whenever the host driver writes to the stateful BAR region. See section "Driver Write" for more information.

Configuration

<table>
<thead>
<tr>
<th>Description</th>
<th>API to Set the Configuration</th>
<th>API to Query Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register to the event</td>
<td>doca_devemu_pci_dev_event_bar_stateful_region_driver_write_register</td>
<td>doca_devemu_pci_cap_type_get_max_bar_stateful_regions</td>
</tr>
</tbody>
</table>

If there are multiple stateful regions for the same device, then registration is done separately for each region. The details provided on registration (i.e., bar_id and start address) must match a region previously configured for PCIe type.

Trigger Condition

The event is triggered anytime the host driver writes to the stateful region. See section "Driver Write" for more information.

Output

Common output as described in DOCA Core Event.
Additionally, the event callback receives an event object of type `struct
doca_devemu_pci_dev_event_bar_stateful_region_driver_write` which can be used to retrieve:

- The DOCA DevEmu PCI Device representing the emulated device that triggered the event – `doca_devemu_pci_dev_event_bar_stateful_region_driver_write_get_pci_dev`
- The ID of the BAR containing the stateful region – `doca_devemu_pci_dev_event_bar_stateful_region_driver_write_get_bar_id`
- The start address of the stateful region – `doca_devemu_pci_dev_event_bar_stateful_region_driver_write_get_bar_region_start_addr`

**Event Handling**

Once the event is triggered, it means that the host driver has written to someplace in the region.

The user must perform either of the following:

- Query the new values of the stateful region – `doca_devemu_pci_dev_query_bar_stateful_region_values`
- Modify the values of the stateful region – `doca_devemu_pci_dev_modify_bar_stateful_region_values`

It is possible also to do both. However, it is important that the memory areas that the host wrote to are either queried or overwritten with a modify operation.

**Note**

Failure to do so results in a recurring event. For example, if the host wrote to the first half of the region, but BlueField Arm only queries the second half of the region after receiving the event. Then the library retriggers the event, assuming that the user did not handle the event.
PCI Device DB

After the PCIe device has been created, it can be used to create DB objects, each DB object represents a DB resources identified by a DB ID. See Generic Data Path (DB BAR Region).

When creating the DB, the DB ID must be provided, this can hold different meaning for DB by offset and DB by data. The DB object can then be used to get a notification to the DPA once a driver write occurs, and to fetch the latest value using the DPA.

Configuration

The flow for creating and configuring a DB should be as follows:

1. Create the DB object:
   
   arm> doca_devemu_pci_db_create_on_dpa

2. (Optional) Query the DB value:
   
   arm> doca_devemu_pci_db_query_value

3. (Optional) Modify the DB value:
   
   arm> doca_devemu_pci_db_modify_value

4. Get the DB DPA handle for referencing the DB from the DPA:
5. Bind the DB to the DB completion context using the handle from the previous step:

```
dpa> doca_dpa_dev_devemu_pci_db_completion_bind_db
```

⚠️ **Warning**

It is important to perform this step before the next one. Otherwise, the DB completion context will start receiving completions for an unbound DB.

6. Start the DB to start receiving completions on DPA:

```
arm> doca_devemu_pci_db_start
```

ℹ️ **Info**

Once DB is started, a completion is immediately generated on the DPA.

Similarly the flow for destroying a DB would look as follows:

1. Stop the DB to stop receiving completions:

```
arm> doca_devemu_pci_db_stop
```
2. Acknowledge all completions related to this DB:

```bash
dpa> doca_dpa_dev_devemu_pci_db_completion_ack
```

3. Unbind the DB from the DB completion context:

```bash
dpa> doca_dpa_dev_devemu_pci_db_completion_unbind_db
```

⚠️ **Warning**

Make sure to not perform this step more than once.

4. Destroy the DB object:
Fetching DBs on DPA

To fetch DBs on DPA, a DB completion context can be used. The DB completion context serves the following purposes:

- Notifying a DPA thread that a DB value has been updated (wakes up thread)
- Providing information about which DB has been updated

The following flow shows how to use the same DB completion context to get notified whenever any of the DBs are updated, and to find which DBs were actually updated, and finally to get the DBs' values:

1. Get DB completion element:
   
   ```
   doca_dpa_dev_devemu_pci_get_db_completion
   ```

2. Get DB from completion:
   
   ```
   doca_dpa_dev_devemu_pci_db_completion_element_get_db_properties
   ```

3. Store the DB (e.g., in an array).

4. Repeat steps 1-3 until there are no more completions.

5. Acknowledge the number of received completions:
   
   ```
   doca_dpa_dev_devemu_pci_db_completion_ack
   ```
6. Request notification on DPA for the next completion:

```
doca_dpa_dev_devemu_pci_db_completion_request_notification
```

7. Go over the DBs stored in step 3 and for each DB:

1. Request a notification for the next time the host driver writes to this DB:

```
doca_dpa_dev_devemu_pci_db_request_notification
```

2. Get the most recent value of the DB:

```
doca_dpa_dev_devemu_pci_db_get_value
```

**Query/Modify DB from Arm**

It is possible to query the DB value of a particular DB using `doca_devemu_pci_db_query_value` on the Arm. Similarly, it is possible to modify the DB value using `doca_devemu_pci_db_modify_value`. When modifying the DB value, the side effects of such modification is the same as if the host driver updated the DB value.

**Tip**

Querying and modifying operations from the Arm are time consuming and should be used in the control path only. Fetching DBs on DPA is the recommended approach for retrieval of DB values in the data path.

**PCle Device MSI-X Vector**

After the PCIe device has been created, it can be used to create MSI-X objects. Each MSI-X object represents an MSI-X vector identified by the vector index.

The MSI-X object can be used to send a notification to the host driver from the DPA.

**Configuration**

The MSI-X object can be created using `doca_devemu_pci_msix_create_on_dpa`. An MSI-X vector index must be provided during creation, this is a value in the range \([0, \text{num}_{\text{msix}}]\), such that \(\text{num}_{\text{msix}}\) is the value previously set using `doca_devemu_pci_type_set_num_msix`.

Once the MSI-X object is created, `doca_devemu_pci_msix_get_dpa_handle` can be used to get a DPA handle for use within the DPA.

**Raising MSI-X**

The MSI-X object can be used on the DPA to raise an MSI-X vector using `doca_dpa_dev_devemu_pci_msix_raise`.

**DOCA DevEmu Generic Samples**

This section describes DOCA DevEmu Generic samples.

The samples illustrate how to use the DOCA DevEmu Generic API to do the following:

- List details about emulated devices with same generic type
- Create and hot-plug/hot-unplug an emulated device with a generic type
- Handle Host driver write using stateful region
- Handle Host driver write using DB region
- Raise MSI-X to the Host driver
• Perform DMA operation to copy memory buffer between the Host driver and the DPU Arm

**Structure**

All the samples utilize the same generic PCI type. The configurations of the type reside in
/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h

The structure for some samples is as follows:

• /opt/mellanox/doca/samples/doca_devemu/<sample directory>
  
  1. dpu
    
    1. host
    2. device
  
  2. host

Samples following this structure will have two binaries: dpu (1) and host (2), the former should be run on the BlueField and represents the controller of the emulated device, while the latter should be run on the host and represents the host driver.

For simplicity, the host (2) side is based on the VFIO driver, allowing development of a driver in user-space.

Within the dpu (a) directory, there is a host (a) and device (b) directories. host in this case refers to the BlueField Arm processor, while device refers to the DPA processor. Both directories are compiled into a single binary.

**Running the Samples**

1. Refer to the following documents:
   
   • [NVIDIA DOCA Installation Guide for Linux](#) for details on how to install BlueField-related software.
   
   • [NVIDIA DOCA Troubleshooting Guide](#) for any issue you may encounter with the installation, compilation, or execution of DOCA samples.
2. To build a given sample:

```
cd /opt/mellanox/doca/samples/doca_devemu/<sample_name>[/dpu or /host]
meson /tmp/build
ninja -C /tmp/build
```

### Info

The binary `doca_<sample_name>[_dpu or _host]` is created under `/tmp/build/`.

3. Sample (e.g., `doca_devemu_pci_device_db`) usage:

1. **BlueField side** (`doca_devemu_pci_device_db_dpu`):

   Usage: `doca_devemu_pci_device_db_dpu [DOCA Flags] [Program Flags]`

   **DOCA Flags:**
   - `-h, --help` Print a help synopsis
   - `-v, --version` Print program version information
   - `-l, --log-level` Set the (numeric) log level for the program <10=DISABLE, 20=Critical, 30=Error, 40=Warning, 50=Info, 60=Debug, 70=Trace>
   - `--sdk-log-level` Set the SDK (numeric) log level for the program <10=DISABLE, 20=Critical, 30=Error, 40=Warning, 50=Info, 60=Debug, 70=Trace>
   - `-j, --json <path>` Parse all command flags from an input json file

   **Program Flags:**
   - `-p, --pci-addr` The DOCA device PCI address. Format: XXXX:XX:XX.X or XX:XX.X
   - `-u, --vuid` DOCA Devemu emulated device VUID. Sample will use this device to handle Doorbells from Host
   - `-r, --region-index` The index of the DB region as defined in `devemu_pci_type_config.h`. Integer
   - `-i, --db-id` The DB ID of the DB. Sample will listen on DBs related to this DB ID. Integer
2. Host side (doca_devemu_pci_device_db_host):

Usage: doca_devemu_pci_device_db_host [DOCA Flags] [Program Flags]

DOCA Flags:
- `--help` Print a help synopsis
- `--version` Print program version information
- `--log-level` Set the (numeric) log level for the program <10=DISABLE, 20=CRITICAL, 30=ERROR, 40=WARNING, 50=INFO, 60=DEBUG, 70=TRACE>

Program Flags:
- `--pci-addr` PCI address of the emulated device. Format: XXXX:XX:XX.X
- `--vfio-group` VFIO group ID of the device. Integer
- `--region-index` The index of the DB region as defined in devemu_pci_type_config.h. Integer
- `--db-index` The index of the Doorbell to write to. The sample will write at byte offset (db-index * db-stride)
- `--db-value` A 4B value to write to the Doorbell. Will be written in Big Endian

4. For additional information per sample, use the `-h` option:

```
/tmp/build/<sample_name> -h
```

Additional sample setup:

- The BlueField samples require the emulated device to be already hot-plugged:
  - Such samples expect the VUID of the hot-plugged device (-u, --vuid)
  - The list sample can be used to find if any hot-plugged devices exist and what their VUID is
  - The hot-plug sample can be used to hot plug a device if no such device already exists
• The host samples require the emulated device to be already hot-plugged and that the device is bound to the VFIO driver:
  
  ○ The samples expect 2 parameters `-p (--pci-addr)` and `-g (--vfio-group)` of the emulated device as seen by the host

  ○ The **PCI Device List** sample can be used from the BlueField to find the PCIe address of the emulated device on the host

  ○ Once the PCIe address is found, the host can use the script
    
    `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py` to bind the VFIO driver

    ```
    $ sudo python3 /opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py
    <pcie-address-of-emulated-dev>
    ```

    - The script is a python3 script which expects the PCIe address of the emulated device as a positional argument (e.g., 0000:3e:00.0)
    - The script outputs the VFIO group ID
    - The script must be used only once after the device is hot-plugged towards the host for the first time

• The hot-unplug sample requires that the device be unbound from the VFIO driver:

  ○ Use the script located at
    
    `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py` from the host to unbind the VFIO driver as follows:

    ```
    $ sudo python3 /opt/mellanox/doca/samples/doca_devemu/devemu_pci_vfio_bind.py
    <pcie-address-of-emulated-dev> --unbind
    ```

    - This python3 script expects the PCIe address of the emulated device as a positional argument (e.g., 0000:3e:00.0) along with the `--unbind` argument
Samples

PCI Device List

This sample illustrates how to list all emulated devices that have the generic type configured in `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.

The sample logic includes:

1. Initializing the generic PCIe type based on
   `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.

2. Creating a list of all emulated devices belonging to this type.

3. Iterating over the emulated devices.

4. Dumping their VUID.

5. Dumping their PCIe address as seen by the host.

6. Releasing the resources.

References:

- `/opt/mellanox/doca/samples/doca_devemu/`
  - `devemu_pci_device_list/`
    - `devemu_pci_device_list_sample.c`
    - `devemu_pci_device_list_main.c`
  - `meson.build`
    - `devemu_pci_common.h; devemu_pci_common.c`
    - `devemu_pci_type_config.h`

PCI Device Hot-Plug
This sample illustrates how to create and hot-plug/hot-unplug an emulated device that has the generic type configured in 
/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h.

The sample logic includes:

1. Initializing the generic PCIe type based on 
   /opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h.

2. Acquiring the emulated device representor:
   - If the user did not provide VUID as input, then creating and using a new emulated device.
   - If the user provided VUID as an input, then searching for an existing emulated device with a matching VUID and using it.

3. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).

4. Registering to the PCIe device’s hot-plug state change event.

5. Initializing hot-plug/hot-unplug of the device:
   1. If the user did not provide VUID as input, then initializing hot-plug flow of the device.
   2. If the user provided VUID as input, then initializing hot-unplug flow of the device.

6. Using the PE to poll for hot-plug state change event.

7. Waiting until hot-plug state transitions to expected state (power on or power off).

8. Cleaning up resources.
   - If hot-unplug was requested, then the emulated device is destroyed as well.
   - Otherwise, the emulated device persists.

References:
PCI Device Stateful Region

This sample illustrates how the host driver can write to a stateful region, and how the BlueField Arm can handle the write operation.

This sample consists of a host sample and BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

1. Initializing the generic PCIe type based on
   
   /opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h.

2. Acquiring the emulated device representor that matches the provided VUID.

3. Creating a PCIe device context to manage the emulated device, and connecting it to a progress engine (PE).

4. For each stateful region configured in
   
   /opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h, registering to the PCIe device's stateful region write event.

5. Using the PE to poll for driver write to any of the stateful regions.

   - Every time the host driver writes to the stateful region, the handler is invoked and performs the following:
1. Queries the values of the stateful region that the host wrote to.

2. Logs the values of the stateful region.

   - The sample polls indefinitely until the user presses [Ctrl+c] to close the sample.

6. Cleaning up resources.

The host sample logic includes:

1. Initializing the VFIO device with a matching PCIe address and VFIO group.

2. Mapping the stateful memory region from the BAR to the process address space.

3. Writing the values provided as input to the beginning of the stateful region.

PCI Device DB

This sample illustrates how the host driver can ring the doorbell and how the BlueField can retrieve the doorbell value. The sample also demonstrates how to handle FLR.

This sample consists of a host sample and BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

- Host (BlueField Arm) logic:

  1. Initializing the generic PCIe type based on
     
     /opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h.

  2. Initializing DPA resources:

     1. Creating DPA instance, and associating it with the DPA application.

     2. Creating DPA thread and associating it with the DPA DB handler.

     3. Creating DB completion context and associating it with the DPA thread.

  3. Acquiring the emulated device representor that matches the provided VUID.

  4. Creating a PCIe device context to manage the emulated device, and connecting it to progress engine (PE).

  5. Registering to the context state changes event.

  6. Registering to the PCIe device FLR event.

  7. Using the PE to poll for any of the following:

     1. Every time the PCIe device context state transitions to running, the handler performs the following:

        1. Creates a DB object.

        2. Makes RPC to DPA, to initialize the DB object.
2. Every time the PCIe device context state transitions to stopping, the handler performs the following:
   1. Makes RPC to DPA, to un-initialize the DB object.
   2. Destroys the DB object.

3. Every time the host driver initializes or destroys the VFIO device, an FLR event is triggered. The FLR handler performs the following:
   1. Destroys DB object.
   2. Stops the PCIe device context.
   3. Starts the PCIe device context again.

4. The sample polls indefinitely until the user presses [Ctrl+c] to close the sample.

   ![Note](image)

   During this time, the DPA may start receiving DBs from the host.

8. Cleaning up resources.

   • Device (BlueField DPA) logic:

   1. Initializing application RPC:

      1. Setting the global context to point to the DB completion context DPA handle.
      2. Binding DB to the doorbell completion context.

   2. Un-initializing application RPC:

      1. Unbinding DB from the doorbell completion context.
3. DB handler:

1. Getting DB completion element from completion context.

2. Getting DB handle from the DB completion element.

3. Acknowledging the DB completion element.

4. Requesting notification from DB completion context.

5. Requesting notification from DB.

6. Getting DB value from DB.

The host sample logic includes:

1. Initializing the VFIO device with its matching PCIe address and VFIO group.

2. Mapping the DB memory region from the BAR to the process address space.

3. Writing the value provided as input to the DB region at the given offset.

This sample illustrates how BlueField can raise an MSI-X vector, sending a signal towards the host, and shows how the host can retrieve this signal.

This sample consists of a host sample and a BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

- Host (BlueField Arm) logic:
  
  1. Initializing the generic PCIe type based on
     /opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h.

  2. Initializing DPA resources:
     
     1. Creating a DPA instance and associating it with the DPA application.

     2. Creating a DPA thread and associating it with the DPA DB handler.

  3. Acquiring the emulated device representor that matches the provided VUID.

  4. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).

  5. Creating an MSI-X vector and acquiring its DPA handle.

  6. Sending an RPC to the DPA to raise the MSI-X vector.

  7. Cleaning up resources.
● Device (BlueField DPA) logic:

1. Raising the MSI-X RPC by using the MSI-X vector handle.

The host sample logic includes:

1. Initializing the VFIO device with the matching PCIe address and VFIO group.

2. Mapping each MSI-X vector to a different FD.

3. Reading events from the FDs in a loop.

   1. Once the DPU raises MSI-X, the FD matching the MSI-X vector returns an event which is then printed to the screen.

   2. The sample polls the FDs indefinitely until the user presses [Ctrl+c] to close the sample.

PCI Device DMA

This sample illustrates how the host driver can set up memory for DMA, then the DPU can use that memory to copy a string from the BlueField to the host and from the host to the BlueField.

This sample consists of a host sample and a BlueField sample. It is necessary to follow the additional sample setup detailed previously.

The BlueField sample logic includes:

1. Initializing the generic PCIe type based on 
   `/opt/mellanox/doca/samples/doca_devemu/devemu_pci_type_config.h`.

2. Acquiring the emulated device representor that matches the provided VUID.

3. Creating a PCIe device context to manage the emulated device and connecting it to a progress engine (PE).

4. Creating a DMA context to use for copying memory across the host and BlueField.

5. Setting up an mmap representing the host driver memory buffer.

6. Setting up an mmap representing a local memory buffer.

7. Use the DMA context to copy memory from host to BlueField.

8. Use the DMA context to copy memory from BlueField to host.

9. Cleaning up resources.

The host sample logic includes:

1. Initializing the VFIO device with the matching PCIe address and VFIO group.
2. Allocating memory buffer.

3. Mapping the memory buffer to I/O memory. The BlueField can now access the memory using the I/O address through DMA.

4. Copying the string provided by user to the memory buffer.

5. Waiting for the BlueField to write to the memory buffer.

6. Un-mapping the memory buffer.

7. Cleaning up resources.
