

## **Function `holoscan::viz::ImageCudaDevice`**

# Table of contents

Function Documentation

---

- Defined in File [holoviz.hpp](#)

## Function Documentation

```
void holoscan::viz::ImageCudaDevice(uint32_t width, uint32_t height, ImageFormat fmt,  
CUdeviceptr device_ptr, size_t row_pitch = 0)
```

Defines the image data for this layer, source is CUDA device memory.

If the image has a alpha value it's multiplied with the layer opacity.

If fmt is a depth format, the image will be interpreted as a depth image, and will be written to the depth buffer when rendering the color image from a separate invocation of `Image*()` for the same layer. This enables depth-compositing image layers with other Holoviz layers. Supported depth formats are: D16\_UNORM, X8\_D24\_UNORM, D32\_SFLOAT.

### Parameters

- **width** – width of the image
- **height** – height of the image
- **fmt** – image format
- **device\_ptr** – CUDA device memory pointer
- **row\_pitch** – the number of bytes between each row, if zero then data is assumed to be contiguous in memory
