Preface

This guide is part of a set of manuals that describe how to use The Portland Group (PGI) Fortran compilers and program development tools integrated with Microsoft Visual Studio. These tools, combined with Visual Studio and assorted libraries, are collectively known as PGI Visual Fortran[®], or PVF[®]. You can use PVF to edit, compile, debug, optimize, and profile serial and parallel applications for x86 processor-based systems.

The *PGI Visual Fortran Reference Manual* is the reference companion to the *PGI Visual Fortran User's Guide* which provides operating instructions for both the Visual Studio integrated development environment as well as command-level compilation and general information about PGI's compilers. Neither guide teaches the Fortran programming language.

Audience Description

This manual is intended for scientists and engineers using PGI Visual Fortran. To fully understand this guide, you should be aware of the role of high-level languages, such as Fortran, in the software development process; and you should have some level of understanding of programming. PGI Visual Fortran is available on a variety of x86 or x64 hardware platforms and variants of the Windows operating system. You need to be familiar with the basic commands available on your system.

Compatibility and Conformance to Standards

Your system needs to be running a properly installed and configured version of PVE. For information on installing PVE, refer to the Release Notes and Installation Guide included with your software.

For further information, refer to the following:

- *American National Standard Programming Language FORTRAN*, ANSI X3. -1978 (1978).
- *ISO/IEC 1539-1 : 1991, Information technology – Programming Languages – Fortran*, Geneva, 1991 (Fortran 90).
- *ISO/IEC 1539-1 : 1997, Information technology – Programming Languages – Fortran*, Geneva, 1997 (Fortran 95).
- *Fortran 95 Handbook Complete ISO/ANSI Reference*, Adams et al, The MIT Press, Cambridge, Mass, 1997.
- *OpenMP Application Program Interface*, Version 2.5, May 2005, <http://www.openmp.org>.

- *Programming in VAX Fortran*, Version 4.0, Digital Equipment Corporation (September, 1984).
- *IBM VS Fortran*, IBM Corporation, Rev. GC26-4119.
- Military Standard, Fortran, DOD Supplement to American National Standard Programming Language Fortran, ANSI x.3-1978, MIL-STD-1753 (November 9, 1978).

Organization

Users typically begin by wanting to know how to use a product and often then find that they need more information and facts about specific areas of the product. Knowing *how* as well as *why* you might use certain options or perform certain tasks is key to using the PGI compilers and tools effectively and efficiently. However, once you have this knowledge and understanding, you very likely might find yourself wanting to know much more about specific areas or specific topics.

To facilitate ease of use, this manual contains detailed reference information about specific aspects of the compiler, such as the details of compiler options, directives, and more. This guide contains these chapters:

[Chapter 1, “*Fortran Data Types*”](#) describes the data types that are supported by the PGI Fortran compilers.

[Chapter 2, “*Command-Line Options Reference*”](#) provides a detailed description of each command-line option.

[Chapter 3, “*OpenMP Reference Information*”](#) contains detailed descriptions of each of the OpenMP directives that PGI supports.

[Chapter 4, “*PGI Accelerator Compilers Reference*”](#) contains detailed descriptions of each of the PGI Accelerator directives, runtime routines, and environment variables that PGI supports.

[Chapter 5, “*Directives Reference*”](#) contains detailed descriptions of PGI’s proprietary directives.

[Chapter 6, “*Run-time Environment*”](#) describes the programming model supported for compiler code generation, including register conventions and calling conventions for x86 and x64 processor-based systems running a Windows operating system.

[Chapter 7, “*PVF Properties*”](#) provides a description of Property Pages that PGI supports.

[Chapter 8, “*PVF Build Macros*”](#) provides a description of the build macros that PVF supports.

[Chapter 9, “*Fortran Module/Library Interfaces for Windows*”](#) provides a description of the Fortran module library interfaces that PVF supports.

[Chapter 10, “*Messages*”](#) provides a list of compiler error messages.

Hardware and Software Constraints

This guide describes versions of PGI Visual Fortran that are intended for use on x86 and x64 processor-based systems. Details concerning environment-specific values and defaults and system-specific features or limitations are presented in the release notes delivered with PGI Visual Fortran.

Conventions

The *PGI Visual Fortran Reference Manual* uses the following conventions:

italic

Italic font is for emphasis.

Constant Width

Constant width font is for commands, filenames, directories, examples and for language statements in the text, including assembly language statements.

[item1]

Square brackets indicate optional items. In this case item1 is optional.

{ item2 | item 3 }

Braces indicate that a selection is required. In this case, you must select either item2 or item3.

filename...

Ellipsis indicate a repetition. Zero or more of the preceding item may occur. In this example, multiple filenames are allowed.

FORTRAN

Fortran language statements are shown in the text of this guide using upper-case characters and a reduced point size.

The PGI compilers and tools are supported on both 32-bit and 64-bit variants of Windows operating systems on a variety of x86-compatible processors. There are a wide variety of releases and distributions of each of these types of operating systems. Further, the *PGI Visual Fortran Reference Manual* uses a number of terms with respect to these platforms.

For a complete definition of these terms and other terms in this guide with which you may be unfamiliar, PGI provides a glossary of terms which you can access at www.pgroup.com/support/definitions.btm.

AMD64	Large arrays	SSE	Win32
barcelona	-mcmodel=small	SSE1	Win64
DLL	-mcmodel=medium	SSE2	Windows
driver	MPI	SSE3	x64
dynamic library	MPICH	SSE4A and ABM	x86
EM64T	multi-core	SSSE3	x87
hyperthreading (HT)	NUMA	static linking	
IA32	shared library		

The following table lists the PGI compilers and tools and their corresponding commands:

Table 1. PGI Compilers and Commands

Compiler or Tool	Language or Function	Command
PGF77	FORTRAN 77	pgf77
PGF95	Fortran 90/95/2003	pgf95
PGFORTRAN	PGI Fortran	pgfortran
PGPROF	Performance profiler	pgprof

Note

The commands **pgf95** and **pgfortran** are equivalent.

In general, the designation *PGI Fortran* is used to refer to The Portland Group's Fortran 90/95/2003 compiler, and *pgfortran* is used to refer to the command that invokes the compiler. A similar convention is used for each of the PGI compilers and tools.

For simplicity, examples of command-line invocation of the compilers generally reference the *pgfortran* command, and most source code examples are written in Fortran. Usage of the *PGF77* compiler, whose features are a subset of *PGF95* or *PGFORTRAN*, is similar.

There are a wide variety of x86-compatible processors in use. All are supported by the PGI compilers and tools. Most of these processors are forward-compatible, but not backward-compatible, meaning that code compiled to target a given processor will not necessarily execute correctly on a previous-generation processor.

A table listing the processor options that PGI supports is available in the Release Notes. The table also includes the features utilized by the PGI compilers that distinguish them from a compatibility standpoint.

In this manual, the convention is to use "x86" to specify the group of processors that are "32-bit" but not "64-bit." The convention is to use "x64" to specify the group of processors that are both "32-bit" and "64-bit." x86 processor-based systems can run only 32-bit operating systems. x64 processor-based systems can run either 32-bit or 64-bit operating systems, and can execute all 32-bit x86 binaries in either case. x64 processors have additional registers and 64-bit addressing capabilities that are utilized by the PGI compilers and tools when running on a 64-bit operating system. The prefetch, SSE1, SSE2 and SSE3 processor features further distinguish the various processors. Where such distinctions are important with respect to a given compiler option or feature, it is explicitly noted in this manual.

Note

The default for performing scalar floating-point arithmetic is to use SSE instructions on targets that support SSE1 and SSE2.

Related Publications

The following documents contain additional information related to the x86 and x64 architectures, and the compilers and tools available from The Portland Group.

- *PGI Fortran Reference* manual describes the FORTRAN 77, Fortran 90/95, Fortran 2003, and HPF statements, data types, input/output format specifiers, and additional reference material related to use of the PGI Fortran compilers.

Chapter 1. Fortran Data Types

This chapter describes the scalar and aggregate data types recognized by the PGI Fortran compilers, the format and alignment of each type in memory, and the range of values each type can have on x86 or x64 processor-based systems running a 32-bit operating system. For more information on x86-specific data representation, refer to the System V Application Binary Interface, Processor Supplement, listed in “[Related Publications](#),” on [page xxi](#). This chapter specifically does not address x64 processor-based systems running a 64-bit operating system, because the application binary interface (ABI) for those systems is still evolving. For the latest version of the ABI, refer to www.x86-64.org/abi.pdf.

Fortran Data Types

Fortran Scalars

A scalar data type holds a single value, such as the integer value 42 or the real value 112.6. The next table lists scalar data types, their size, format and range. [Table 1.2, “Real Data Type Ranges,” on page 2](#) shows the range and approximate precision for Fortran real data types. [Table 1.3, “Scalar Type Alignment,” on page 2](#) shows the alignment for different scalar data types. The alignments apply to all scalars, whether they are independent or contained in an array, a structure or a union.

Table 1.1. Representation of Fortran Data Types

Fortran Data Type	Format	Range
INTEGER	2's complement integer	-2^{31} to $2^{31}-1$
INTEGER*2	2's complement integer	-32768 to 32767
INTEGER*4	2's complement integer	-2^{31} to $2^{31}-1$
INTEGER*8	2's complement integer	-2^{63} to $2^{63}-1$
LOGICAL	32-bit value	true or false
LOGICAL*1	8-bit value	true or false
LOGICAL*2	16-bit value	true or false
LOGICAL*4	32-bit value	true or false
LOGICAL*8	64-bit value	true or false

Fortran Data Type	Format	Range
BYTE	2's complement	-128 to 127
REAL	Single-precision floating point	10^{-37} to $10^{38(1)}$
REAL*4	Single-precision floating point	10^{-37} to $10^{38(1)}$
REAL*8	Double-precision floating point	10^{-307} to $10^{308(1)}$
DOUBLE PRECISION	Double-precision floating point	10^{-307} to $10^{308(1)}$
COMPLEX	Single-precision floating point	10^{-37} to $10^{38(1)}$
DOUBLE COMPLEX	Double-precision floating point	10^{-307} to $10^{308(1)}$
COMPLEX*16	Double-precision floating point	10^{-307} to $10^{308(1)}$
CHARACTER*n	Sequence of n bytes	

⁽¹⁾ Approximate value

The logical constants `.TRUE.` and `.FALSE.` are all ones and all zeroes, respectively. Internally, the value of a logical variable is true if the least significant bit is one and false otherwise. When the option `-Munixlogical` is set, a logical variable with a non-zero value is true and with a zero value is false.

Note

A variable of logical type may appear in an arithmetic context, and the logical type is then treated as an integer of the same size.

Table 1.2. Real Data Type Ranges

Data Type	Binary Range	Decimal Range	Digits of Precision
REAL	-2^{-126} to 2^{128}	10^{-37} to $10^{38(1)}$	7-8
REAL*8	-2^{-1022} to 2^{1024}	10^{-307} to $10^{308(1)}$	15-16

Table 1.3. Scalar Type Alignment

This Type...	...Is aligned on this size boundary
LOGICAL*1	1-byte
LOGICAL*2	2-byte
LOGICAL*4	4-byte
LOGICAL*8	8-byte
BYTE	1-byte
INTEGER*2	2-byte
INTEGER*4	4-byte
INTEGER*8	8-byte
REAL*4	4-byte
REAL*8	8-byte

This Type...	...Is aligned on this size boundary
COMPLEX*8	4-byte
COMPLEX*16	8-byte

FORTRAN 77 Aggregate Data Type Extensions

The PGF77 compiler supports de facto standard extensions to FORTRAN 77 that allow for aggregate data types. An aggregate data type consists of one or more scalar data type objects. You can declare the following aggregate data types:

- An **array** consists of one or more elements of a single data type placed in contiguous locations from first to last.
- A **structure** can contain different data types. The members are allocated in the order they appear in the definition but may not occupy contiguous locations.
- A **union** is a single location that can contain any of a specified set of scalar or aggregate data types. A union can have only one value at a time. The data type of the union member to which data is assigned determines the data type of the union after that assignment.

The alignment of an array, a structure or union (an aggregate) affects how much space the object occupies and how efficiently the processor can address members. Arrays use the alignment of their members.

Array types

align according to the alignment of the array elements. For example, an array of INTEGER*2 data aligns on a 2byte boundary.

Structures and Unions

align according to the alignment of the most restricted data type of the structure or union. In the next example, the union aligns on a 4byte boundary since the alignment of c, the most restrictive element, is four.

```

STRUCTURE /astr/
UNION
  MAP
    INTEGER*2 a ! 2 bytes
  END MAP
  MAP
    BYTE b ! 1 byte
  END MAP
  MAP
    INTEGER*4 c ! 4 bytes
  END MAP
END UNION
END STRUCTURE

```

Structure alignment can result in unused space called *padding*. Padding between members of the structure is called *internal padding*. Padding between the last member and the end of the space is called *tail padding*.

The offset of a structure member from the beginning of the structure is a multiple of the member's alignment. For example, since an INTEGER*2 aligns on a 2-byte boundary, the offset of an INTEGER*2 member from the beginning of a structure is a multiple of two bytes.

Fortran 90 Aggregate Data Types (Derived Types)

The Fortran 90 standard added formal support for aggregate data types. The TYPE statement begins a derived type data specification or declares variables of a specified user-defined type. For example, the following would define a derived type ATTENDEE:

```
TYPE ATTENDEE
  CHARACTER (LEN=30) NAME
  CHARACTER (LEN=30) ORGANIZATION
  CHARACTER (LEN=30) EMAIL
END TYPE ATTENDEE
```

In order to declare a variable of type ATTENDEE and access the contents of such a variable, code such as the following would be used:

```
TYPE (ATTENDEE) ATTLIST(100)
. . .
ATTLIST(1)%NAME = 'JOHN DOE'
```

Chapter 2. Command-Line Options Reference

A command-line option allows you to specify specific behavior when a program is compiled and linked. Compiler options perform a variety of functions, such as setting compiler characteristics, describing the object code to be produced, controlling the diagnostic messages emitted, and performing some preprocessor functions. Most options that are not explicitly set take the default settings. This reference chapter describes the syntax and operation of each compiler option. For easy reference, the options are arranged in alphabetical order.

For an overview and tips on which options are best for which tasks, refer to Chapter 6, “Using Command Line Options” in the PGI Compiler User’s Guide, which also provides summary tables of the different options.

This chapter uses the following notation:

[item]

Square brackets indicate that the enclosed item is optional.

{item | item}

Braces indicate that you must select one and only one of the enclosed items. A vertical bar (|) separates the choices.

...

Horizontal ellipses indicate that zero or more instances of the preceding item are valid.

PGI Compiler Option Summary

The following tables include all the PGI compiler options that are not language-specific. The options are separated by category for easier reference.

For a complete description of each option, see the detailed information later in this chapter.

Build-Related PGI Options

The options included in the following table are the ones you use when you are initially building your program or application.

Table 2.1. PGI Build-Related Compiler Options

Option	Description
<code>—#</code>	Display invocation information.
<code>—###</code>	Shows but does not execute the driver commands (same as the option <code>—dryrun</code>).
<code>—Bdynamic</code>	Compiles for and links to the DLL version of the PGI runtime libraries.
<code>—Bstatic_pgi</code>	Compiles for and links to the static version of the PGI runtime libraries.
<code>—c</code>	Stops after the assembly phase and saves the object code in <code>filename.o</code> .
<code>—D<args></code>	Defines a preprocessor macro.
<code>—dryrun</code>	Shows but does not execute driver commands.
<code>—drystdinc</code>	Displays the standard include directories and then exists the compiler.
<code>—E</code>	Stops after the preprocessing phase and displays the preprocessed file on the standard output.
<code>—F</code>	Stops after the preprocessing phase and saves the preprocessed file in <code>filename.f</code> (this option is only valid for the PGI Fortran compilers).
<code>--flagcheck</code>	Simply return zero status if flags are correct.
<code>—flags</code>	Display valid driver options.
<code>—I<dirname></code>	Adds a directory to the search path for <code>#include</code> files.
<code>—i2</code> , <code>—i4</code> and <code>—i8</code>	<code>—i2</code> : Treat INTEGER variables as 2 bytes. <code>—i4</code> : Treat INTEGER variables as 4 bytes. <code>—i8</code> : Treat INTEGER and LOGICAL variables as 8 bytes and use 64-bits for INTEGER*8 operations.
<code>—K<flag></code>	Requests special compilation semantics with regard to conformance to IEEE 754.
<code>--keeplnk</code>	If the compiler generates a temporary indirect file for a long linker command, preserves the temporary file instead of deleting it.
<code>—L<dirname></code>	Specifies a library directory.

Option	Description
-l<library>	Loads a library.
-m	Displays a link map on the standard output.
-M<pgflag>	Selects variations for code generation and optimization.
-module <moduledir>	Save/search for module files in directory <moduledir>.
-mp[=all, align,bind,[no]numa]	Interpret and process user-inserted shared-memory parallel programming directives (see Chapters 5 and 6).
-noswitcherror	Ignore unknown command line switches after printing an warning message.
-o	Names the object file.
-pc <val>	(-tp px/p5/p6/piii targets only) Set precision globally for x87 floating-point calculations; must be used when compiling the main program. <val> may be one of 32, 64 or 80.
-pgf77libs	Append PGF77 runtime libraries to the link line.
-pgf90libs	Append PGF90/PGF95/PGFORTRAN runtime libraries to the link line.
-r4 and -r8	-r4: Interpret DOUBLE PRECISION variables as REAL. -r8: Interpret REAL variables as DOUBLE PRECISION.
-rc file	Specifies the name of the driver's startup file.
-S	Stops after the compiling phase and saves the assembly-language code in filename.s.
-show	Display driver's configuration parameters after startup.
-silent	Do not print warning messages.
-time	Print execution times for the various compilation steps.
-u<symbol>	Initializes the symbol table with <symbol>, which is undefined for the linker. An undefined symbol triggers loading of the first member of an archive library.
-U<symbol>	Undefine a preprocessor macro.
-V[release_number]	Displays the version messages and other information, or allows invocation of a version of the compiler other than the default.
-v	Displays the compiler, assembler, and linker phase invocations.
-W	Passes arguments to a specific phase.
-w	Do not print warning messages.

PGI Debug-Related Compiler Options

The options included in the following table are the ones you typically use when you are debugging your program or application.

Table 2.2. PGI Debug-Related Compiler Options

Option	Description
<code>-C</code>	(Fortran only) Generates code to check array bounds.
<code>-c</code>	Instrument the generated executable to perform array bounds checking at runtime.
<code>-E</code>	Stops after the preprocessing phase and displays the preprocessed file on the standard output.
<code>--flagcheck</code>	Simply return zero status if flags are correct.
<code>-flags</code>	Display valid driver options.
<code>-g</code>	Includes debugging information in the object module.
<code>-gopt</code>	Includes debugging information in the object module, but forces assembly code generation identical to that obtained when <code>-gopt</code> is not present on the command line.
<code>-K<flag></code>	Requests special compilation semantics with regard to conformance to IEEE 754.
<code>--keeplnk</code>	If the compiler generates a temporary indirect file for a long linker command, preserves the temporary file instead of deleting it.
<code>-M<pgflag></code>	Selects variations for code generation and optimization.
<code>-pc <val></code>	(<code>-tp px/p5/p6/piii</code> targets only) Set precision globally for x87 floating-point calculations; must be used when compiling the main program. <code><val></code> may be one of 32, 64 or 80.
<code>-[no]traceback</code>	Adds debug information for runtime traceback for use with the environment variable <code>PGI_TERM</code> .

PGI Optimization-Related Compiler Options

The options included in the following table are the ones you typically use when you are optimizing your program or application code.

Table 2.3. Optimization-Related PGI Compiler Options

Option	Description
<code>-fast</code>	Generally optimal set of flags for targets that support SSE capability.
<code>-fastsse</code>	Generally optimal set of flags for targets that include SSE/SSE2 capability.
<code>-M<pgflag></code>	Selects variations for code generation and optimization.
<code>-mp[=all, align,bind,[no]numa]</code>	Interpret and process user-inserted shared-memory parallel programming directives (see Chapters 5 and 6).
<code>-O<level></code>	Specifies code optimization level where <level> is 0, 1, 2, 3, or 4.
<code>-pc <val></code>	(<code>-tp px/p5/p6/piii</code> targets only) Set precision globally for x87 floating-point calculations; must be used when compiling the main program. <val> may be one of 32, 64 or 80.

PGI Linking and Runtime-Related Compiler Options

The options included in the following table are the ones you typically use to define parameters related to linking and running your program or application code.

Table 2.4. Linking and Runtime-Related PGI Compiler Options

Option	Description
<code>-Bdynamic</code>	Compiles for and links to the DLL version of the PGI runtime libraries.
<code>-Bstatic_pgi</code>	Compiles for and links to the static version of the PGI runtime libraries.
<code>-byteswapio</code>	(Fortran only) Swap bytes from big-endian to little-endian or vice versa on input/output of unformatted data
<code>-i2</code>	Treat INTEGER variables as 2 bytes.
<code>-i4</code>	Treat INTEGER variables as 4 bytes.
<code>-i8</code>	Treat INTEGER and LOGICAL variables as 8 bytes and use 64-bits for INTEGER*8 operations.
<code>-K<flag></code>	Requests special compilation semantics with regard to conformance to IEEE 754.
<code>-M<pgflag></code>	Selects variations for code generation and optimization.

Generic PGI Compiler Options

The following descriptions are for all the PGI options. For easy reference, the options are arranged in alphabetical order. For a list of options by tasks, refer to the tables in the beginning of this chapter.

—#

Displays the invocations of the compiler, assembler and linker.

Default: The compiler does not display individual phase invocations.

Usage: The following command-line requests verbose invocation information.

```
$ pgfortran -# prog.f
```

Description: The —# option displays the invocations of the compiler, assembler and linker. These invocations are command-lines created by the driver from your command-line input and the default value.

Related options: —Minfo, —V, —v.

—###

Displays the invocations of the compiler, assembler and linker, but does not execute them.

Default: The compiler does not display individual phase invocations.

Usage: The following command-line requests verbose invocation information.

```
$ pgfortran -### myprog.f
```

Description: Use the —### option to display the invocations of the compiler, assembler and linker but not to execute them. These invocations are command lines created by the compiler driver from the `rc` files and the command-line options.

Related options: —#, —dryrun, —Minfo, —V

—Bdynamic

Compiles for and links to the DLL version of the PGI runtime libraries.

Default: The compiler uses static libraries.

Usage: You can create the DLL `obj1.dll` and its import library `obj1.lib` using the following series of commands:

```
% pgfortran -Bdynamic -c object1.f
% pgfortran -Mmakedll object1.obj -o obj1.dll
```

Then compile the main program using this command:

```
$ pgfortran -# prog.f
```

For a complete example, refer to the example: “Build a DLL: Fortran” in the “Creating and Using Libraries” chapter of the PGI Compiler User’s Guide.

Description: Use this option to compile for and link to the DLL version of the PGI runtime libraries. This flag is required when linking with any DLL built by the PGI compilers. This flag corresponds to the `/MD` flag used by Microsoft’s `cl` compilers.

Note

On Windows, `-Bdynamic` must be used for *both* compiling and linking.

When you use the PGI compiler flag `-Bdynamic` to create an executable that links to the DLL form of the runtime, the executable built is smaller than one built without `-Bdynamic`. The PGI runtime DLLs, however, must be available on the system where the executable is run. The `-Bdynamic` flag must be used when an executable is linked against a DLL built by the PGI compilers.

Note

C++ on Windows does not support `-Bdynamic`.

Related options: `-Bstatic`, `-Mmakedll`

`-Bstatic`

Compiles for and links to the static version of the PGI runtime libraries.

Default: The compiler uses static libraries.

Usage: The following command line explicitly compiles for and links to the static version of the PGI runtime libraries:

```
% pgfortran -Bstatic -c object1.f
```

Description: You can use this option to explicitly compile for and link to the static version of the PGI runtime libraries.

Note

On Windows, `-Bstatic` must be used for *both* compiling and linking.

For more information on using static libraries on Windows, refer to “Creating and Using Static Libraries on Windows” in the “Creating and Using Libraries” chapter of the PGI Compiler User’s Guide.

Related options: `-Bdynamic`, `-Bstatic_pgi`, `-Mdll`

-Bstatic_pgi

Linux only. Compiles for and links to the static version of the PGI runtime libraries. Implies `-Mnorpath`.

Default: The compiler uses static libraries.

Usage: The following command line explicitly compiles for and links to the static version of the PGI runtime libraries:

```
% pgfortran -Bstatic -c object1.f
```

Description: You can use this option to explicitly compile for and link to the static version of the PGI runtime libraries.

Note

On Linux, `-Bstatic_pgi` results in code that runs on most Linux systems without requiring a Portability package.

For more information on using static libraries on Windows, refer to “Creating and Using Static Libraries on Windows” in the “Creating and Using Libraries” chapter of the PGI Compiler User’s Guide.

Related options: `-Bdynamic`, `-Bstatic`, `-Mdll`

-byteswapio

Swaps the byte-order of data in unformatted Fortran data files on input/output.

Default: The compiler does not byte-swap data on input/output.

Usage: The following command-line requests that byte-swapping be performed on input/output.

```
$ pgfortran -byteswapio myprog.f
```

Description: Use the `-byteswapio` option to swap the byte-order of data in unformatted Fortran data files on input/output. When this option is used, the order of bytes is swapped in both the data and record control words; the latter occurs in unformatted sequential files.

You can use this option to convert big-endian format data files produced by most RISC workstations and high-end servers to the little-endian format used on x86 or x64 systems on the fly during file reads/writes.

This option assumes that the record layouts of unformatted sequential access and direct access files are the same on the systems. It further assumes that the IEEE representation is used for floating-point numbers. In particular, the format of unformatted data files produced by PGI Fortran compilers is identical to the format used on Sun and SGI workstations; this format allows you to read and write unformatted Fortran data files produced on those platforms from a program compiled for an x86 or x64 platform using the `-byteswapio` option.

Related options: None.

-C

Enables array bounds checking. This option only applies to the PGI Fortran compilers.

Default: The compiler does not enable array bounds checking.

Usage: In this example, the compiler instruments the executable produced from `myprog.f` to perform array bounds checking at runtime:

```
$ pgfortran -C myprog.f
```

Description: Use this option to enable array bounds checking. If an array is an assumed size array, the bounds checking only applies to the lower bound. If an array bounds violation occurs during execution, an error message describing the error is printed and the program terminates. The text of the error message includes the name of the array, the location where the error occurred (the source file and the line number in the source), and information about the out of bounds subscript (its value, its lower and upper bounds, and its dimension).

Related options: `-M[no]bounds`.

-c

Halts the compilation process after the assembling phase and writes the object code to a file.

Default: The compiler produces an executable file (does not use the `-c` option).

Usage: In this example, the compiler produces the object file `myprog.obj` in the current directory.

```
$ pgfortran -c myprog.f
```

Description: Use the `-c` option to halt the compilation process after the assembling phase and write the object code to a file. If the input file is `filename.f`, the output file is `.`

Related options: `-E`, `-Mkeepasm`, `-o`, and `-S`.

-D

Creates a preprocessor macro with a given value.

Note

You can use the `-D` option more than once on a compiler command line. The number of active macro definitions is limited only by available memory.

Syntax:

```
-Dname [=value]
```

Where `name` is the symbolic name and `value` is either an integer value or a character string.

Default: If you define a macro name without specifying a value, the preprocessor assigns the string 1 to the macro name.

Usage: In the following example, the macro `PATHLENGTH` has the value 256 until a subsequent compilation. If the `-D` option is not used, `PATHLENGTH` is set to 128.

```
$ pgfortran -DPATHLENGTH=256 myprog.F
```

The source text in `myprog.F` is this:

```
#ifndef PATHLENGTH
#define PATHLENGTH 128
#endif
SUBROUTINE SUB
CHARACTER*PATHLENGTH path
...
END
```

Description: Use the `-D` option to create a preprocessor macro with a given value. The value must be either an integer or a character string.

You can use macros with conditional compilation to select source text during preprocessing. A macro defined in the compiler invocation remains in effect for each module on the command line, unless you remove the macro with an `#undef` preprocessor directive or with the `-U` option. The compiler processes all of the `-U` options in a command line after processing the `-D` options.

To set this option in PVF, use the Fortran | Preprocessor | Preprocessor Definitions property, described in “Preprocessor Definitions” on page 381.

Related options: `-U`

`-dryrun`

Displays the invocations of the compiler, assembler, and linker but does not execute them.

Default: The compiler does not display individual phase invocations.

Usage: The following command line requests verbose invocation information.

```
$ pgfortran -dryrun myprog.f
```

Description: Use the `-dryrun` option to display the invocations of the compiler, assembler, and linker but not have them executed. These invocations are command lines created by the compiler driver from the `rc` files and the command-line supplied with `-dryrun`.

Related options: `-Minfo`, `-V`, `-###`

–drystdinc

Displays the standard include directories and then exits the compiler.

Default: The compiler does not display standard include directories.

Usage: The following command line requests a display for the standard include directories.

```
$ pgfortran -drystdinc myprog.f
```

Description: Use the `–drystdinc` option to display the standard include directories and then exit the compiler.

Related options:None.

–E

Halts the compilation process after the preprocessing phase and displays the preprocessed output on the standard output.

Default: The compiler produces an executable file.

Usage: In the following example the compiler displays the preprocessed `myprog.f` on the standard output.

```
$ pgfortran -E myprog.f
```

Description: Use the `–E` option to halt the compilation process after the preprocessing phase and display the preprocessed output on the standard output.

Related options: `–C`, `–c`, `–Mkeepasm`, `–o`, `–F`, `–S`.

–F

Stops compilation after the preprocessing phase.

Default: The compiler produces an executable file.

Usage: In the following example the compiler produces the preprocessed file `myprog.f` in the current directory.

```
$ pgfortran -F myprog.F
```

Description: Use the `–F` option to halt the compilation process after preprocessing and write the preprocessed output to a file. If the input file is `filename.F`, then the output file is `filename.f`.

Related options: `–c`, `–E`, `–Mkeepasm`, `–o`, `–S`

–fast

Enables vectorization with SSE instructions, cache alignment, and flushz for 64-bit targets.

Default: The compiler enables vectorization with SSE instructions, cache alignment, and flushz.

Usage: In the following example the compiler produces vector SSE code when targeting a 64-bit machine.

```
$ pgfortran -fast vadd.f95
```

Description: When you use this option, a generally optimal set of options is chosen for targets that support SSE capability. In addition, the appropriate `–tp` option is automatically included to enable generation of code optimized for the type of system on which compilation is performed. This option enables vectorization with SSE instructions, cache alignment, and flushz.

Note

Auto-selection of the appropriate `–tp` option means that programs built using the `–fastsse` option on a given system are not necessarily backward-compatible with older systems.

Note

C/C++ compilers enable `–Mautoinline` with `–fast`.

To set this option in PVE, use the Fortran | General | Optimization property, described in “Optimization” on page 378.

Related options: `–O`, `–Munroll`, `–Mnoframe`, `–Mscalarsse`, `–Mvect`, `–Mcache_align`, `–tp`, `–M[no]autoinline`

–fastsse

Synonymous with `–fast`.

--flagcheck

Causes the compiler to check that flags are correct then exit without any compilation occurring.

Default: The compiler begins a compile without the additional step to first validate that flags are correct.

Usage: In the following example the compiler checks that flags are correct, and then exits.

```
$ pgfortran --flagcheck myprog.f
```

Description: Use this option to make the compiler check that flags are correct and then exit. If flags are all correct then the compiler returns a zero status. No compilation occurs.

Related options: None

–flags

Displays driver options on the standard output.

Default: The compiler does not display the driver options.

Usage: In the following example the user requests information about the known switches.

```
$ pgfortran -flags
```

Description: Use this option to display driver options on the standard output. When you use this option with `–v`, in addition to the valid options, the compiler lists options that are recognized and ignored.

Related options: `–#`, `–###`, `–v`

–g

Instructs the compiler to include symbolic debugging information in the object module.

Default: The compiler does not put debugging information into the object module.

Usage: In the following example, the object file `myprog.obj` contains symbolic debugging information.

```
$ pgfortran -c -g myprog.f
```

Description: Use the `–g` option to instruct the compiler to include symbolic debugging information in the object module. Debuggers, such as *PGDBG*, require symbolic debugging information in the object module to display and manipulate program variables and source code.

If you specify the `–g` option on the command-line, the compiler sets the optimization level to `–O0` (zero), unless you specify the `–O` option. For more information on the interaction between the `–g` and `–O` options, see the `–O` entry. Symbolic debugging may give confusing results if an optimization level other than zero is selected.

Note

Including symbolic debugging information increases the size of the object module.

To set this option in PVE, use the Fortran | General | Debug Information Format property, described in “Debug Information Format” on page 377.

Related options: `–O`, `–gopt`

-gopt

Instructs the compiler to include symbolic debugging information in the object file, and to generate optimized code identical to that generated when `-g` is not specified.

Default: The compiler does not put debugging information into the object module.

Usage: In the following example, the object file `myprog.obj` contains symbolic debugging information.

```
$ pgfortran -c -gopt myprog.f
```

Description: Using `-g` alters how optimized code is generated in ways that are intended to enable or improve debugging of optimized code. The `-gopt` option instructs the compiler to include symbolic debugging information in the object file, and to generate optimized code identical to that generated when `-g` is not specified.

To set this option in PVE, use the Fortran | General | Debug Information Format property described in “Debug Information Format” on page 377.

Related options: `-g`, `-M<pgflag>`

-help

Used with no other options, `-help` displays options recognized by the driver on the standard output. When used in combination with one or more additional options, usage information for those options is displayed to standard output.

Default: The compiler does not display usage information.

Usage: In the following example, usage information for `-Minline` is printed to standard output.

```
$ pgcc -help -Minline
-Minline[=lib:<inlib>|<func>|except:<func>|
name:<func>|size:<n>|levels:<n>]
Enable function inlining
lib:<extlib> Use extracted functions from extlib
<func> Inline function func
except:<func> Do not inline function func
name:<func> Inline function func
size:<n> Inline only functions smaller than n
levels:<n> Inline n levels of functions
-Minline Inline all functions that were extracted
```

In the following example, usage information for `-help` shows how groups of options can be listed or examined according to function.

```
$ pgcc -help -help
-help[=groups|asm|debug|language|linker|opt|other|
overall|phase|prepro|suffix|switch|target|variable]
```

Description: Use the `-help` option to obtain information about available options and their syntax. You can use `-help` in one of three ways:

- Use `-help` with no parameters to obtain a list of all the available options with a brief one-line description of each.
- Add a parameter to `-help` to restrict the output to information about a specific option. The syntax for this usage is this:

```
-help <command line option>
```

- Add a parameter to `-help` to restrict the output to a specific set of options or to a building process. The syntax for this usage is this:

```
-help=<subgroup>
```

The following table lists and describes the subgroups available with `-help`.

Table 2.5. Subgroups for `-help` Option

Use this <code>-help</code> option	To get this information...
<code>-help=asm</code>	A list of options specific to the assembly phase.
<code>-help=debug</code>	A list of options related to debug information generation.
<code>-help=groups</code>	A list of available switch classifications.
<code>-help=language</code>	A list of language-specific options.
<code>-help=linker</code>	A list of options specific to link phase.
<code>-help=opt</code>	A list of options specific to optimization phase.
<code>-help=other</code>	A list of other options, such as ANSI conformance pointer aliasing for C.
<code>-help=overall</code>	A list of options generic to any PGI compiler.
<code>-help=phase</code>	A list of build process phases and to which compiler they apply.
<code>-help=prepro</code>	A list of options specific to the preprocessing phase.
<code>-help=suffix</code>	A list of known file suffixes and to which phases they apply.
<code>-help=switch</code>	A list of all known options; this is equivalent to usage of <code>-help</code> without any parameter.
<code>-help=target</code>	A list of options specific to target processor.
<code>-help=variable</code>	A list of all variables and their current value. They can be redefined on the command line using syntax <code>VAR=VALUE</code> .

Related options: `-#`, `-###`, `-show`, `-V`, `-flags`

–I

Adds a directory to the search path for files that are included using either the INCLUDE statement or the preprocessor directive #include.

Default: The compiler searches only certain directories for included files.

Syntax:

```
-Idirectory
```

Where directory is the name of the directory added to the standard search path for include files.

Usage: In the following example, the compiler first searches the directory `mydir` and then searches the default directories for include files.

```
$ pgfortran -Imydir
```

Description: Adds a directory to the search path for files that are included using the INCLUDE statement or the preprocessor directive #include. Use the –I option to add a directory to the list of where to search for the included files. The compiler searches the directory specified by the –I option before the default directories.

The Fortran INCLUDE statement directs the compiler to begin reading from another file. The compiler uses two rules to locate the file:

1. If the file name specified in the INCLUDE statement includes a path name, the compiler begins reading from the file it specifies.
2. If no path name is provided in the INCLUDE statement, the compiler searches (in order):
 - Any directories specified using the –I option (in the order specified)
 - The directory containing the source file
 - The current directory

For example, the compiler applies rule (1) to the following statements:

```
INCLUDE '/bob/include/file1' (absolute path name)
INCLUDE '../..file1' (relative path name)
```

and rule (2) to this statement:

```
INCLUDE 'file1'
```

To set this option in PVE, use the Fortran | General | Additional Include Directories property, described in “Additional Include Directories” on page 375, or the Fortran | Preprocessor | Additional Include Directories property, described in “Additional Include Directories” on page 380.

Related options: –Mnostdinc

-i2, -i4 and -i8

Treat INTEGER and LOGICAL variables as either two, four, or eight bytes.

Default: The compiler treats INTEGER and LOGICAL variables as four bytes.

Usage: In the following example, using the `-i8` switch causes the integer variables to be treated as 64 bits.

```
$ pgfortran -i8 int.f
```

`int.f` is a function similar to this:

```
int.f
print *, "Integer size:", bit_size(i)
end
```

Description: Use this option to treat INTEGER and LOGICAL variables as either two, four, or eight bytes. INTEGER*8 values not only occupy 8 bytes of storage, but operations use 64 bits, instead of 32 bits.

Related options: None

-K<flag>

Requests that the compiler provide special compilation semantics.

Default: The compiler does not provide special compilation semantics.

Syntax:

`-K<flag>`

Where `flag` is one of the following:

<code>ieee</code>	Perform floating-point operations in strict conformance with the IEEE 754 standard. Some optimizations are disabled, and on some systems a more accurate math library is linked if <code>-Kieee</code> is used during the link step.
	To set this option in PVE, use the Fortran Floating Point Options IEEE Arithmetic property, described in “IEEE Arithmetic” on page 391.
<code>noieee</code>	Default flag. Use the fastest available means to perform floating-point operations, link in faster non-IEEE libraries if available, and disable underflow traps.

trap=option Controls the behavior of the processor when floating-point exceptions occur.
Possible options include:
[,option]...

- fp
- align (ignored)
- inv
- denorm
- divz
- ovf
- unf
- inexact

Usage: In the following example, the compiler performs floating-point operations in strict conformance with the IEEE 754 standard

```
$ pgfortran -Kieee myprog.f
```

Description: Use `-K` to instruct the compiler to provide special compilation semantics.

The default is `-Knoieee`.

`-Ktrap` is only processed by the compilers when compiling main functions or programs. The options `inv`, `denorm`, `divz`, `ovf`, `unf`, and `inexact` correspond to the processor's exception mask bits: invalid operation, denormalized operand, divide-by-zero, overflow, underflow, and precision, respectively. Normally, the processor's exception mask bits are *on*, meaning that floating-point exceptions are masked—the processor recovers from the exceptions and continues. If a floating-point exception occurs and its corresponding mask bit is *off*, or "unmasked", execution terminates with an arithmetic exception (C's SIGFPE signal).

`-Ktrap=fp` is equivalent to `-Ktrap=inv,divz,ovf`.

To set this option in PVE, use the Fortran | Floating Point Options | Floating Point Exception Handling property, described in "Floating Point Exception Handling" on page 390

Note

The PGI compilers do not support exception-free execution for `-Ktrap=inexact`. The purpose of this hardware support is for those who have specific uses for its execution, along with the appropriate signal handlers for handling exceptions it produces. It is not designed for normal floating point operation code support.

Related options: None.

--keeplnk

(Windows only.) Preserves the temporary file when the compiler generates a temporary indirect file for a long linker command.

Usage: In the following example the compiler preserves each temporary file rather than deleting it.

```
$ pgfortran --keeplnk myprog.f
```

Description: If the compiler generates a temporary indirect file for a long linker command, use this option to instruct the compiler to preserve the temporary file instead of deleting it.

Related options: None.

-L

Specifies a directory to search for libraries.

Note

Multiple **-L** options are valid. However, the position of multiple **-L** options is important relative to **-l** options supplied.

Syntax:

```
-Ldirectory
```

Where *directory* is the name of the library directory.

Default: The compiler searches the standard library directory.

Usage: In the following example, the library directory is `/lib` and the linker links in the standard libraries required by PGFORTRAN from this directory.

```
$ pgfortran -L/lib myprog.f
```

In the following example, the library directory `/lib` is searched for the library file `libx.a` and both the directories `/lib` and `/libz` are searched for `liby.a`.

```
$ pgfortran -L/lib -lx -L/libz -ly myprog.f
```

Use the **-L** option to specify a directory to search for libraries. Using **-L** allows you to add directories to the search path for library files.

Related options: **-l**

-l<library>

Instructs the linker to load the specified library. The linker searches <library> in addition to the standard libraries.

Note

The linker searches the libraries specified with -l in order of appearance *before* searching the standard libraries.

Syntax:

```
-llibrary
```

Where library is the name of the library to search.

Usage: In the following example, if the standard library directory is /lib the linker loads the library /lib/libmylib.a, in addition to the standard libraries.

```
$ pgfortran myprog.f -lmylib
```

Description: Use this option to instruct the linker to load the specified library. The compiler prepends the characters lib to the library name and adds the .a extension following the library name. The linker searches each library specifies before searching the standard libraries.

Related options: -L

-m

Displays a link map on the standard output.

Default: The compiler does display the link map and does not use the -m option.

Usage: When the following example is executed on Windows, pgfortran creates a link map in the file myprog.map.

```
$ pgfortran -m myprog.f
```

Description: Use this option to display a link map.

- On Linux, the map is written to stdout.
- On Windows, the map is written to a .map file whose name depends on the executable. If the executable is myprog.f, the map file is in myprog.map.

Related options: -c, -o, -s, -u

-m32

Use the 32-bit compiler for the default processor type.

Usage: When the following example is executed on Windows, pgfortran uses the 32-bit compiler for the default processor type.

```
$ pgfortran -m32 myprog.f
```

Description: Use this option to specify the 32-bit compiler as the default processor type.

–m64

Use the 64-bit compiler for the default processor type.

Usage: When the following example is executed on Windows, pgfortran uses the 64-bit compiler for the default processor type.

```
$ pgfortran -m64 myprog.f
```

Description: Use this option to specify the 64-bit compiler as the default processor type.

–M<pgflag>

Selects options for code generation. The options are divided into the following categories:

Code generation	Fortran Language Controls	Optimization
Environment	C/C++ Language Controls	Miscellaneous
Inlining		

The following table lists and briefly describes the options alphabetically and includes a field showing the category. For more details about the options as they relate to these categories, refer to “–M Options by Category” on page 113.

Table 2.6. –M Options Summary

pgflag	Description	Category
allocatable=95 03	Controls whether to use Fortran 95 or Fortran 2003 semantics in allocatable array assignments.	Fortran Language
anno	Annotate the assembly code with source code.	Miscellaneous
[no]autoinline	C/C++ when a function is declared with the inline keyword, inline it at –O2 and .	Inlining
[no]backslash	Determines how the backslash character is treated in quoted strings (pgf77, pgf95, pgfortran, and pghpf only).	Fortran Language
[no]bounds	Specifies whether array bounds checking is enabled or disabled.	Miscellaneous
byteswapio	Swap byte-order (big-endian to little-endian or vice versa) during I/O of Fortran unformatted data.	Miscellaneous
cache_align	Where possible, align data objects of size greater than or equal to 16 bytes on cache-line boundaries.	Optimization
chkfpstk	Check for internal consistency of the x87 FP stack in the prologue of a function and after returning from a function or subroutine call (–tp px/p5/p6/piii targets only).	Miscellaneous

pgflag	Description	Category
chkptr	Check for NULL pointers (pgf95, pgfortran, and pghpf only).	Miscellaneous
chkstk	Check the stack for available space upon entry to and before the start of a parallel region. Useful when many private variables are declared.	Miscellaneous
concur	Enable auto-concurrentization of loops. Multiple processors or cores will be used to execute parallelizable loops.	Optimization
cpp	Run the PGI cpp-like preprocessor without performing subsequent compilation steps.	Miscellaneous
cray	Force Cray Fortran (CF77) compatibility (pgf77, pgf95, pgfortran, and pghpf only).	Optimization
cuda	Enables Cuda Fortran.	Fortran Language
[no]daz	Do/don't treat denormalized numbers as zero.	Code Generation
[no]dclchk	Determines whether all program variables must be declared (pgf77, pgf95, pgfortran, and pghpf only).	Fortran Language
[no]defaultunit	Determines how the asterisk character ("*") is treated in relation to standard input and standard output (regardless of the status of I/O units 5 and 6, pgf77, pgf95, pgfortran, and pghpf only).	Fortran Language
[no]depchk	Checks for potential data dependencies.	Optimization
[no]dse	Enables [disables] dead store elimination phase for programs making extensive use of function inlining.	Optimization
[no]dlines	Determines whether the compiler treats lines containing the letter "D" in column one as executable statements (pgf77, pgf95, pgfortran, and pghpf only).	Fortran Language
dollar,char	Specifies the character to which the compiler maps the dollar sign code.	Fortran Language
[no]dwarf	Specifies not to add DWARF debug information.	Code Generation
dwarf1	When used with <code>-g</code> , generate DWARF1 format debug information.	Code Generation
dwarf2	When used with <code>-g</code> , generate DWARF2 format debug information.	Code Generation
dwarf3	When used with <code>-g</code> , generate DWARF3 format debug information.	Code Generation

pgflag	Description	Category
<code>extend</code>	Instructs the compiler to accept 132-column source code; otherwise it accepts 72-column code (<code>pgf77</code> , <code>pgf95</code> , <code>pgfortran</code> , and <code>pghpf</code> only).	Fortran Language
<code>extract</code>	invokes the function extractor.	Inlining
<code>fixed</code>	Instructs the compiler to assume F77-style fixed format source code (<code>pgf95</code> , <code>pgfortran</code> , and <code>pghpf</code> only).	Fortran Language
<code>[no]flushz</code>	Do/don't set SSE flush-to-zero mode	Code Generation
<code>[no]fpapprox</code>	Specifies not to use low-precision fp approximation operations.	Optimization
<code>[no]f[=option]</code>	Perform certain floating point intrinsic functions using relaxed precision.	Optimization
<code>free</code>	Instructs the compiler to assume F90-style free format source code (<code>pgf95</code> , <code>pgfortran</code> and <code>pghpf</code> only).	Fortran Language
<code>func32</code>	The compiler aligns all functions to 32-byte boundaries.	Code Generation
<code>gccbug[s]</code>	Matches behavior of certain gcc bugs	Miscellaneous
<code>info</code>	Prints informational messages regarding optimization and code generation to standard output as compilation proceeds.	Miscellaneous
<code>inform</code>	Specifies the minimum level of error severity that the compiler displays.	Miscellaneous
<code>inline</code>	Invokes the function inliner.	Inlining
<code>instrumentation</code>	Generates code to enable instrumentation of functions.	Miscellaneous
<code>[no]ipa</code>	Invokes interprocedural analysis and optimization.	Optimization
<code>[no]iomutex</code>	Determines whether critical sections are generated around Fortran I/O calls.	Fortran Language
<code>keepasm</code>	Instructs the compiler to keep the assembly file.	Miscellaneous
<code>largeaddressaware</code>	Enables support for 64-bit indexing and single static data objects of size larger than 2GB.	Code Generation
<code>[no]large_arrays</code>	Enables support for 64-bit indexing and single static data objects of size larger than 2GB.	Code Generation
<code>[no]loop32</code>	Aligns/does not align innermost loops on 32 byte boundaries with <code>-tp barcelona</code>	Code Generation
<code>[no]lre</code>	Disable/enable loop-carried redundancy elimination.	Optimization

pgflag	Description	Category
list	Specifies whether the compiler creates a listing file.	Miscellaneous
makedll	Generate a dynamic link library (DLL).	Miscellaneous
makeimplib	Passes the -def switch to the librarian without a deffile, when used without -def:deffile.	Miscellaneous
mpi=option	Link to MPI libraries: MPICH1, MPICH2, or Microsoft MPI libraries	Code Generation
neginfo	Instructs the compiler to produce information on why certain optimizations are not performed.	Miscellaneous
noframe	Eliminates operations that set up a true stack frame pointer for functions.	Optimization
noi4	Determines how the compiler treats INTEGER variables.	Optimization
nomain	When the link step is called, don't include the object file that calls the Fortran main program. .	Code Generation
noopenmp	When used in combination with the -mp option, the compiler ignores OpenMP parallelization directives or pragmas, but still processes SGI-style parallelization directives or pragmas.	Miscellaneous
nopgdlmain	Do not link the module containing the default DllMain() into the DLL.	Miscellaneous
nosgimp	When used in combination with the -mp option, the compiler ignores SGI-style parallelization directives or pragmas, but still processes OpenMP directives or pragmas.	Miscellaneous
nostdinc	Instructs the compiler to not search the standard location for include files. To set this option in PVE, use the Fortran Preprocessor Ignore Standard Include Path property.	Environment
nostdlib	Instructs the linker to not link in the standard libraries.	Environment
[no]onetrip	Determines whether each DO loop executes at least once.	Language
novintr	Disable idiom recognition and generation of calls to optimized vector functions.	Optimization
pfi	Instrument the generated code and link in libraries for dynamic collection of profile and data information at runtime.	Optimization
pre	Read a pgfi.out trace file and use the information to enable or guide optimizations.	Optimization

pgflag	Description	Category
[no]pre	Force/disable generation of non-temporal moves and prefetching.	Code Generation
[no]prefetch	Enable/disable generation of prefetch instructions.	Optimization
preprocess	Perform cpp-like preprocessing on assembly language and Fortran input source files.	Miscellaneous
prof	Set profile options; function-level and line-level profiling are supported.	Code Generation
[no]r8	Determines whether the compiler promotes REAL variables and constants to DOUBLE PRECISION.	Optimization
[no]r8intrinsic	Determines how the compiler treats the intrinsics CMPLX and REAL.	Optimization
[no]recursive	Allocate / do not allocate local variables on the stack, this allows recursion. SAVED, data-initialized, or namelist members are always allocated statically, regardless of the setting of this switch.	Code Generation
[no]reentrant	Specifies whether the compiler avoids optimizations that can prevent code from being reentrant.	Code Generation
[no]ref_externals	Do/don't force references to names appearing in EXTERNAL statements.	Code Generation
safe_lastval	In the case where a scalar is used after a loop, but is not defined on every iteration of the loop, the compiler does not by default parallelize the loop. However, this option tells the compiler it is safe to parallelize the loop. For a given loop, the last value computed for all scalars make it safe to parallelize the loop.	Code Generation
[no]save	Determines whether the compiler assumes that all local variables are subject to the SAVE statement.	Fortran Language
[no]scalarsse	Do/don't use SSE/SSE2 instructions to perform scalar floating-point arithmetic.	Optimization
[no]second_underscore	Do/don't add the second underscore to the name of a Fortran global if its name already contains an underscore.	Code Generation
[no]signextend	Do/don't extend the sign bit, if it is set.	Code Generation
[no]smart	Do/don't enable optional post-pass assembly optimizer.	Optimization

pgflag	Description	Category
[no]smartalloc[=huge huge:<n> hugebss]	Add a call to the routine mallopt in the main routine. Supports large TLBs on Linux and Windows. <i>Tip.</i> To be effective, this switch must be specified when compiling the file containing the Fortran, C, or C++ main program.	Environment
standard	Causes the compiler to flag source code that does not conform to the ANSI standard.	Fortran Language
[no]stride0	Do/do not generate alternate code for a loop that contains an induction variable whose increment may be zero.	Code Generation
unix	Uses UNIX calling and naming conventions for Fortran subprograms.	Code Generation
[no]unixlogical	Determines how the compiler treats logical values. .	Fortran Language
[no]unroll	Controls loop unrolling.	Optimization
[no]upcase	Determines whether the compiler preserves uppercase letters in identifiers..	Fortran Language
varargs	Forces Fortran program units to assume calls are to C functions with a varargs type interface.	Code Generation
[no]vect	Do/don't invoke the code vectorizer.	Optimization

–module <moduledir>

Allows you to specify a particular directory in which generated intermediate .mod files should be placed.

Default: The compiler places .mod files in the current working directory, and searches only in the current working directory for pre-compiled intermediate .mod files.

Usage: The following command line requests that any intermediate module file produced during compilation of myprog.f be placed in the directory mymods; specifically, the file ./mymods/myprog.mod is used.

```
$ pgfortran -module mymods myprog.f
```

Description: Use the –module option to specify a particular directory in which generated intermediate .mod files should be placed. If the –module <moduledir> option is present, and USE statements are present in a compiled program unit, then <moduledir> is searched for .mod intermediate files *prior* to a search in the default local directory.

To set this option in PVE, use the Fortran | Output | Module Path property, described in “Module Path” on page 376.

Related options: None.

-mp[=all, align,bind,[no]numa]

Instructs the compiler to interpret user-inserted OpenMP shared-memory parallel programming directives, and to generate an executable file which will utilize multiple processors in a shared-memory parallel system.

Default: The compiler interprets user-inserted shared-memory parallel programming directives when linking. To disable this option, use the `-nomp` option when linking.

Usage: The following command line requests processing of any shared-memory directives present in `myprog.f`:

```
$ pgfortran -mp myprog.f
```

Description: Use the `-mp` option to instruct the compiler to interpret user-inserted OpenMP shared-memory parallel programming directives and to generate an executable file which utilizes multiple processors in a shared-memory parallel system.

The suboptions are one or more of the following:

align

Forces loop iterations to be allocated to OpenMP processes using an algorithm that maximizes alignment of vector sub-sections in loops that are both parallelized and vectorized for SSE. This allocation can improve performance in program units that include many such loops. It can also result in load-balancing problems that significantly decrease performance in program units with relatively short loops that contain a large amount of work in each iteration. The `numa` suboption uses `libnuma` on systems where it is available.

allcores

Instructs the compiler to all available cores. You specify this suboption at link time.

bind

Instructs the compiler to bind threads to cores. You specify this suboption at link time.

[no]numa

Uses [does not use] `libnuma` on systems where it is available.

For a detailed description of this programming model and the associated directives, refer to Chapter 9, “Using OpenMP” of the PGI Compiler User’s Guide.

To set this option in PVE, use the Fortran | Language | Enable OpenMP Directives property, described in “Enable OpenMP Directives” on page 384.

Related options: `-Mconcur`, `-Mvect`

-noswitcherror

Issues warnings instead of errors for unknown switches. Ignores unknown command line switches after printing a warning message.

Default: The compiler prints an error message and then halts.

Usage: In the following example, the compiler ignores unknown command line switches after printing a warning message.

```
$ pgfortran -noswitcherror myprog.f
```

Description: Use this option to instruct the compiler to ignore unknown command line switches after printing an warning message.

Tip

You can configure this behavior in the `siterc` file by adding: `set NOSWITCHERROR=1.`

Related options: None.

-O<level>

Invokes code optimization at the specified level.

Default: The compiler optimizes at level 2.

Syntax:

`-O [level]`

Where level is an integer from 0 to 4.

Usage: In the following example, since no `-O` option is specified, the compiler sets the optimization to level 1.

```
$ pgfortran myprog.f
```

In the following example, since no optimization level is specified and a `-O` option is specified, the compiler sets the optimization to level 2.

```
$ pgfortran -O myprog.f
```

Description: Use this option to invoke code optimization at the specified level - one of the following:

0

creates a basic block for each statement. Neither scheduling nor global optimization is done. To specify this level, supply a 0 (zero) argument to the `-O` option.

1

schedules within basic blocks and performs some register allocations, but does no global optimization.

2

performs all level-1 optimizations, and also performs global scalar optimizations such as induction variable elimination and loop invariant movement.

3

level-three specifies aggressive global optimization. This level performs all level-one and level-two optimizations and enables more aggressive hoisting and scalar replacement optimizations that may or may not be profitable.

4

level-four performs all level-one, level-two, and level-three optimizations and enables hoisting of guarded invariant floating point expressions.

To set this option (`-O2` or `-O3`) in PVE, use the Fortran | Optimization | Global Optimizations property, described in “Global Optimizations” on page 378.

Table 2-8 shows the interaction between the `-O` option, `-g` option, `-Mvect`, and `-Mconcur` options.

Table 2.7. Optimization and `-O`, `-g`, `-Mvect`, and `-Mconcur` Options

Optimize Option	Debug Option	<code>-M</code> Option	Optimization Level
none	none	none	1
none	none	<code>-Mvect</code>	2
none	none	<code>-Mconcur</code>	2
none	<code>-g</code>	none	0
<code>-O</code>	none or <code>-g</code>	none	2
<code>-Olevel</code>	none or <code>-g</code>	none	level
<code>-Olevel < 2</code>	none or <code>-g</code>	<code>-Mvect</code>	2
<code>-Olevel < 2</code>	none or <code>-g</code>	<code>-Mconcur</code>	2

Unoptimized code compiled using the option `-O0` can be significantly slower than code generated at other optimization levels. Like the `-Mvect` option, the `-Munroll` option sets the optimization level to level-2 if no `-O` or `-g` options are supplied. The `-gopt` option is recommended for generation of debug information with optimized code. For more information on optimization, refer to Chapter 7, “Optimizing and Parallelizing” in the PGI Compiler User’s Guide.

Related options: `-g`, `-M<pgflag>`, `-gopt`

`-O`

Names the executable file. Use the `-o` option to specify the filename of the compiler object file. The final output is the result of linking.

Syntax:

`-o filename`

Where filename is the name of the file for the compilation output. The filename must not have a .f extension.

Default: The compiler creates executable filenames as needed. If you do not specify the `-o` option, the default filename is the linker output file with a name comprised of the base file name, such as `myprog`, plus the extension `.exe`, for example: `myprog.exe`.

Usage: In the following example, the executable file is `myp.exe` instead of the default `a.outmyprog.exe`.

```
$ pgfortran myprog.f -o myp
```

To set this option in PVE, use the Fortran | Output | Object File Name property, described in “Object File Name” on page 377.

Related options: `-c`, `-E`, `-F`, `-S`

`-pc`

Note

This option is available only for `-tp px/p5/p6/piii` targets.

Allows you to control the precision of operations performed using the x87 floating point unit, and their representation on the x87 floating point stack.

Syntax:

`-pc { 32 | 64 | 80 }`

Usage:

```
$ pgfortran -pc 64 myprog.f
```

Description: The x87 architecture implements a floating-point stack using 8 80-bit registers. Each register uses bits 0-63 as the significant, bits 64-78 for the exponent, and bit 79 is the sign bit. This 80-bit real format is the default format, called the *extended format*. When values are loaded into the floating point stack they are automatically converted into extended real format. The precision of the floating point stack can be controlled, however, by setting the precision control bits (bits 8 and 9) of the floating control word appropriately. In this way, you can explicitly set the precision to standard IEEE double-precision using 64 bits, or to single precision using 32 bits.¹ The default precision is system dependent. To alter the precision in a given program unit, the main program must be compiled with the same `-pc` option. The command line option `-pc val` lets the programmer set the compiler’s precision preference.

Valid values for `val` are:

32 single precision	64 double precision	80 extended precision
---------------------	---------------------	-----------------------

Extended Precision Option – Operations performed exclusively on the floating-point stack using extended precision, without storing into or loading from memory, can cause problems with accumulated values within

¹According to Intel documentation, this only affects the x87 operations of add, subtract, multiply, divide, and square root. In particular, it does not appear to affect the x87 transcendental instructions.

the extra 16 bits of extended precision values. This can lead to answers, when rounded, that do not match expected results.

For example, if the argument to `sin` is the result of previous calculations performed on the floating-point stack, then an 80-bit value used instead of a 64-bit value can result in slight discrepancies. Results can even change sign due to the sin curve being too close to an x-intercept value when evaluated. To maintain consistency in this case, you can assure that the compiler generates code that calls a function. According to the x86 ABI, a function call must push its arguments on the stack (in this way memory is guaranteed to be accessed, even if the argument is an actual constant). Thus, even if the called function simply performs the inline expansion, using the function call as a wrapper to `sin` has the effect of trimming the argument precision down to the expected size. Using the `-Mnobuiltin` option on the command line for C accomplishes this task by resolving all math routines in the library `libm`, performing a function call of necessity. The other method of generating a function call for math routines, but one that may still produce the inline instructions, is by using the `-Kieee` switch.

A second example illustrates the precision control problem using a section of code to determine machine precision:

```
program find_precision
  w = 1.0
100 w=w+w
  y=w+1
  z=y-w
  if (z .gt. 0) goto 100
C now w is just big enough that |((w+1)-w)-1| >= 1
  ...
  print*,w
end
```

In this case, where the variables are implicitly `real*4`, operations are performed on the floating-point stack where optimization removes unnecessary loads and stores from memory. The general case of copy propagation being performed follows this pattern:

```
a = x
y = 2.0 + a
```

Instead of storing `x` into `a`, then loading `a` to perform the addition, the value of `x` can be left on the floating-point stack and added to `2.0`. Thus, memory accesses in some cases can be avoided, leaving answers in the extended real format. If copy propagation is disabled, stores of all left-hand sides will be performed automatically and reloaded when needed. This will have the effect of rounding any results to their declared sizes.

The `find_precision` program has a value of `1.8446744E+19` when executed using default (extended) precision. If, however, `-Kieee` is set, the value becomes `1.6777216E+07` (single precision.) This difference is due to the fact that `-Kieee` disables copy propagation, so all intermediate results are stored into memory, then reloaded when needed. Copy propagation is only disabled for floating-point operations, not integer. With this particular example, setting the `-pc` switch will also adjust the result.

The `-Kieee` switch also has the effect of making function calls to perform all transcendental operations. Except when the `-Mnobuiltin` switch is set in C, the function still produces the x86 machine instruction for computation, and arguments are passed on the stack, which results in a memory store and load.

Finally, `-Kieee` also disables reciprocal division for constant divisors. That is, for a/b with unknown a and constant b , the expression is usually converted at compile time to $a*(1/b)$, thus turning an expensive divide into a relatively fast scalar multiplication. However, numerical discrepancies can occur when this optimization is used.

Understanding and correctly using the `-pc`, `-Mnobuiltin`, and `-Kieee` switches should enable you to produce the desired and expected precision for calculations which utilize floating-point operations.

Related options: `-Kieee`, `-Mnobuiltin`

-pedantic

Prints warnings from included <system header files> .

Default: The compiler prints the warnings from the included system header files.

Usage: In the following example, the compiler prints the warnings from the included system header files.

```
$ pgfortran --pedantic myprog.f
```

Related options:

-pgcplibs

Instructs the compiler to append C++ runtime libraries to the link line for programs built using either PGF90 or PGF77.

Default: The C/C++ compilers do not append the C++ runtime libraries to the link line.

Usage: In the following example the C++ runtime libraries are linked with an object file compiled with `pgf77`.

```
$ pgf90 main.f90 mycpp.o -pgcplibs
```

Description: Use this option to instruct the compiler to append C++ runtime libraries to the link line for programs built using either PGF90 or PGF77.

Related options: `-pgf90libs`, `-pgf77libs`

-pgf77libs

Instructs the compiler to append PGF77 runtime libraries to the link line.

Default: The C/C++ compilers do not append the PGF77 runtime libraries to the link line.

Usage: In the following example a `.c` main program is linked with an object file compiled with `pgf77`.

```
$ pgcc main.c myf77.o -pgf77libs
```

Description: Use this option to instruct the compiler to append PGF77 runtime libraries to the link line.

Related options: `-pgcplibs`, `-pgf90libs`

-pgf90libs

Instructs the compiler to append PGF90/PGF95/PGFORTRAN runtime libraries to the link line.

Default: The C/C++ compilers do not append the PGF90/PGF95/PGFORTRAN runtime libraries to the link line.

Usage: In the following example a .c main program is linked with an object file compiled with pgfortran.

```
$ pgcc main.c myf95.o -pgf90libs
```

Description: Use this option to instruct the compiler to append PGF90/PGF95/PGFORTRAN runtime libraries to the link line.

Related options: `-pgcplibs`, `-pgf77libs`

`-r4` and `-r8`

Interprets DOUBLE PRECISION variables as REAL (`-r4`), or interprets REAL variables as DOUBLE PRECISION (`-r8`).

Usage: In this example, the double precision variables are interpreted as REAL.

```
$ pgfortran -r4 myprog.f
```

Description: Interpret DOUBLE PRECISION variables as REAL (`-r4`) or REAL variables as DOUBLE PRECISION (`-r8`).

Related options: `-i2`, `-i4`, `-i8`, `-nor8`

`-rc`

Specifies the name of the driver startup configuration file. If the file or pathname supplied is not a full pathname, the path for the configuration file loaded is relative to the \$DRIVER path (the path of the currently executing driver). If a full pathname is supplied, that file is used for the driver configuration file.

Syntax:

```
-rc [path] filename
```

Where path is either a relative pathname, relative to the value of \$DRIVER, or a full pathname beginning with `"/`. Filename is the driver configuration file.

Default: The driver uses the configuration file `.pgirc`.

Usage: In the following example, the file `.pgfortranrctest`, relative to `/usr/pgi/linux86/bin`, the value of \$DRIVER, is the driver configuration file.

```
$ pgfortran -rc .pgfortranrctest myprog.f
```

Description: Use this option to specify the name of the driver startup configuration file. If the file or pathname supplied is not a full pathname, the path for the configuration file loaded is relative to the \$DRIVER path - the path of the currently executing driver. If a full pathname is supplied, that file is used for the driver configuration file.

Related options: `-show`

-S

Stops compilation after the compiling phase and writes the assembly-language output to a file.

Default: The compiler does not produce a `.s` file.

Usage: In this example, `pgfortran` produces the file `myprog.s` in the current directory.

```
$ pgfortran -S myprog.f
```

Description: Use this option to stop compilation after the compiling phase and then write the assembly-language output to a file. If the input file is `filename.f`, then the output file is `filename.s`.

Related options: `-c`, `-E`, `-F`, `-Mkeepasm`, `-o`

-show

Produces driver help information describing the current driver configuration.

Default: The compiler does not show driver help information.

Usage: In the following example, the driver displays configuration information to the standard output after processing the driver configuration file.

```
$ pgfortran -show myprog.f
```

Description: Use this option to produce driver help information describing the current driver configuration.

Related options: `-V`, `-v`, `-###`, `-help`, `-rc`

-silent

Do not print warning messages.

Default: The compiler prints warning messages.

Usage: In the following example, the driver does not display warning messages.

```
$ pgfortran -silent myprog.f
```

Description: Use this option to suppress warning messages.

Related options: `-v`, `-V`, `-w`

-stack

(Windows only.) Allows you to explicitly set stack properties for your program.

Default: If `-stack` is not specified, then the defaults are as followed:

Win32

Setting is `-stack:2097152,2097152`, which is approximately 2MB for reserved and committed bytes.

Win64

No default setting

Syntax:

```
-stack={ (reserved bytes) [, (committed bytes)] }{, [no]check }
```

Usage: The following example demonstrates how to reserve 524,288 stack bytes (512KB), commit 262,144 stack bytes for each routine (256KB), and disable the stack initialization code with the `nocheck` argument.

```
$ pgfortran -stack=524288,262144,nocheck myprog.f
```

Description: Use this option to explicitly set stack properties for your program. The `-stack` option takes one or more arguments: (reserved bytes), (committed bytes), [no]check.

reserved bytes

Specifies the total stack bytes required in your program.

committed bytes

Specifies the number of stack bytes that the Operating System will allocate for each routine in your program. This value must be less than or equal to the stack *reserved bytes* value.

Default for this argument is 4096 bytes

[no]check

Instructs the compiler to generate or not to generate stack initialization code upon entry of each routine. Check is the default, so stack initialization code is generated.

Stack initialization code is required when a routine's stack exceeds the *committed bytes* size. When your *committed bytes* is equal to the *reserved bytes* or equal to the stack bytes required for each routine, then you can turn off the stack initialization code using the `-stack=nocheck` compiler option. If you do this, the compiler assumes that you are specifying enough committed stack space; and therefore, your program does not have to manage its own stack size.

For more information on determining the amount of stack required by your program, refer to `-Mchkstk` compiler option, described in “Miscellaneous Controls” on page 151.

Note

`-stack=(reserved bytes) , (committed bytes)` are linker options.

`-stack=[no] check` is a compiler option.

If you specify `-stack=(reserved bytes) , (committed bytes)` on your compile line, it is only used during the link step of your build. Similarly, `-stack=[no] check` can be specified on your link line, but its only used during the compile step of your build.

Related options: `-Mchkstk`

`-ta=nvidia(,nvidia_suboptions),host`

Defines the target accelertator.

Note

This flag is valid only for Fortran and C.

Default: The compiler uses NVIDIA.

Usage: In the following example, NVIDIA is the accelerator target architecture and the accelerator generates code for compute capability 1.3.

```
$ pgfortran -ta=nvidia,cc13
```

Description: Use this option to select the accelerator target and, optionally, to define the type of code to generate.

The `-ta` flag has the following options:

nvidia

Select NVIDIA accelerator target. This option has the following nvidia-suboptions:

analysis

Perform loop analysis only; do not generate GPU code.

cc10

Generate code for compute capability 1.0.

cc11

Generate code for compute capability 1.1.

cc12

Generate code for compute capability 1.2.

cc13

Generate code for compute capability 1.3.

cc20

Generate code for compute capability 2.0.

cc30

Generate code for compute capability 3.0.

cuda2.3 or 2.3

Specify the NVIDIA CUDA 2.3 version of the toolkit.

cuda3.0 or 3.0

Specify the NVIDIA CUDA 3.0 version of the toolkit.

cuda3.1 or 3.1

Specify the NVIDIA CUDA 3.1 version of the toolkit.

cuda3.2 or 3.2

Specify the NVIDIA CUDA 3.2 version of the toolkit.

cuda4.0 or 4.0

Specify the NVIDIA CUDA 4.0 version of the toolkit.

cuda4.1 or 4.1

Specify the NVIDIA CUDA 4.1 version of the toolkit. This is the default.

cuda4.2 or 4.2

Specify the NVIDIA CUDA 4.2 version of the toolkit.

Note

Compiling with the CUDA 3.1, CUDA 3.2, CUDA 4.0, CUDA 4.1 or CUDA 4.2 toolkit, either by using the `-ta=nvidia:cuda3.1`, `-ta=nvidia:cuda3.2`, `-ta=nvidia:cuda4.0`, `-ta=nvidia:cuda4.1` or `-ta=nvidia:cuda4.2` option or by adding `set CUDAVERSION=3.1`, `set CUDAVERSION=3.2`, `set CUDAVERSION=4.0`, `set CUDAVERSION=4.1`, or `set CUDAVERSION=4.2` to the `siterc` file, generates binaries that may not work on machines with a 2.3 CUDA driver.

`pgacceleinfo` prints the driver version as the first line of output.

For a 2.3 driver: CUDA Driver Version 2030

For a 3.0 driver: CUDA Driver Version 3000

For a 3.1 driver: CUDA Driver Version 3010

For a 3.2 driver: CUDA Driver Version 3020

For a 4.0 driver: CUDA Driver Version 4000

For a 4.1 driver: CUDA Driver Version 4010

For a 4.2 driver: CUDA Driver Version 4020

fastmath

Use routines from the fast math library.

[no]flushz

Enable[disable] flush-to-zero mode for floating point computations in the GPU code generated for for PGI Accelerator model compute regions.

keepbin

Keep the binary (.bin) files.

keepgpu

Keep the kernel source (.gpu) files.

keepptx

Keep the portable assembly (.ptx) file for the GPU code.

maxregcount:n

Specify the maximum number of registers to use on the GPU. Leaving this blank indicates no limit.

mul24

Use 24-bit multiplication for subscripting.

nofma

Do not generate fused multiply-add instructions.

time

Link in a limited-profiling library, as described in “Profiling Accelerator Kernels” in the Using an Accelerator chapter of the PGI Compiler User’s Guide.

[no]wait

Wait [do not wait] for each kernel to finish before continuing in the host program.

host

Select NO accelerator target. Generate PGI Unified Binary Code, as described in “PGI Unified Binaries for Accelerators” in the Using an Accelerator chapter of the PGI Compiler User’s Guide.

Related options: `—#`

`—time`

Print execution times for various compilation steps.

Default: The compiler does not print execution times for compilation steps.

Usage: In the following example, `pgfortran` prints the execution times for the various compilation steps.

```
$ pgfortran -time myprog.f
```

Description: Use this option to print execution times for various compilation steps.

Related options: `—#`

`—tp <target> [,target...]`

Sets the target architecture.

Default: The PGI compilers produce code specifically targeted to the type of processor on which the compilation is performed. In particular, the default is to use all supported instructions wherever possible when compiling on a given system.

The default style of code generation is auto-selected depending on the type of processor on which compilation is performed. Further, the `—tp x64` style of unified binary code generation is only enabled by an explicit `—tp x64` option.

Note

Executables created on a given system may not be usable on previous generation systems. (For example, executables created on a Pentium 4 may fail to execute on a Pentium III or Pentium II.)

The `—tp` flags and `—m32/—m64` flags without a bit-length suffix use the current bit width rather than defaulting to 32-bit. For example, if you have the 32-bit driver on your path, then `—tp shanghai` defaults to 32-bit; while if you are using the 64-bit driver, it defaults to 64-bit. For example, `—tp p7 —m64`, `—m64 —tp p7`, `—tp p7-64`, `—m64 —tp p7-64`, and `—tp p7-64 —m64` all mean the same thing.

Usage: In the following example, `pgfortran` sets the target architecture to EM64T:

```
$ pgfortran -tp p7-64 myprog.f
```

Description: Use this option to set the target architecture. By default, the PGI compiler uses all supported instructions wherever possible when compiling on a given system. As a result, executables created on a given system may not be usable on previous generation systems. For example, executables created on a Pentium 4 may fail to execute on a Pentium III or Pentium II.

Processor-specific optimizations can be specified or limited explicitly by using the `-tp` option. Thus, it is possible to create executables that are usable on previous generation systems. With the exception of k8-64, k8-64e, p7-64, and x64, any of these suboptions are valid on any x86 or x64 processor-based system. The k8-64, k8-64e, p7-64 and x64 options are valid only on x64 processor-based systems.

The `-tp x64` option generates unified binary object and executable files, as described in “Using `-tp` to Generate a Unified Binary” on page 90.

To set this option in PVE, use the Fortran | Target Processors | Unified Binary Information property, described in “Unified Binary Information” on page 406.

The following list contains the possible suboptions for `-tp` and the processors that each suboption is intended to target. Options without a bit-length suffix use the current width associated with the driver on your path.

athlon

generate code for AMD Athlon XP/MP and compatible processors.

barcelona

generate code for AMD Opteron/Quadcore and compatible processors. The

barcelona-32

generate 32-bit code for AMD Opteron/Quadcore and compatible processors.

barcelona-64

generate 64-bit code for AMD Opteron/Quadcore and compatible processors.

bulldozer

Generate either 32-bit or 64-bit code for AMD Bulldozer and compatible processors. 32- or 64-bit depends on the driver on your path.

bulldozer-32

generate 32-bit code for AMD Bulldozer and compatible processors.

bulldozer-64

generate 64-bit code for AMD Bulldozer and compatible processors.

core2

generate code for Intel Core 2 Duo and compatible processors.

core2-32

generate 32-bit code for Intel Core 2 Duo and compatible processors.

core2-64

generate 64-bit code for Intel Core 2 Duo EM64T and compatible processors.

istanbul

generate code that is usable on any Istanbul processor-based system.

istanbul-32

generate 32-bit code that is usable on any Istanbul processor-based system.

istanbul-64

generate 64-bit code that is usable on any Istanbul processor-based system.

k8-32

generate 32-bit code for AMD Athlon64, AMD Opteron and compatible processors.

k8-64

generate 64-bit code for AMD Athlon64, AMD Opteron and compatible processors.

k8-64e

generate 64-bit code for AMD Opteron Revision E, AMD Turion, and compatible processors.

nehalem

generate code that is usable on any Nehalem processor-based system.

nehalem-32

generate 32-bit code that is usable on any Nehalem processor-based system.

nehalem-64

generate 64-bit code that is usable on any Nehalem processor-based system.

p6

generate code for Pentium Pro/II/III and AthlonXP compatible processors.

p7

generate code for Pentium 4 and compatible processors.

p7-32

generate 32-bit code for Pentium 4 and compatible processors.

p7-64

generate 64-bit code for Intel P4/Xeon EM64T and compatible processors.

penryn

generate code for Intel Penryn Architecture and compatible processors.

penryn-32

generate 32-bit code for Intel Penryn Architecture and compatible processors.

penryn-64

generate 64-bit code for Intel Penryn Architecture and compatible processors.

piii

generate code for Pentium III and compatible processors, including support for single-precision vector code using SSE instructions.

px

generate code that is usable on any x86 processor-based system.

px-32

generate 32-bit code that is usable on any x86 processor-based system.

sandybridge

Generate either 32-bit or 64-bit code for Intel Sandy Bridge and compatible processors. 32- or 64-bit depends on the driver on your path.

sandybridge-32

generate 32-bit code for Intel Sandy Bridge and compatible processors.

sandybridge-64

generate 64-bit code for Intel Sandy Bridge and compatible processors.

shanghai

generate code that is usable on any AMD Shanghai processor-based system.

shanghai-32

generate 32-bit code that is usable on any AMD Shanghai processor-based system.

shanghai-64

generate 64-bit code that is usable on any AMD Shanghai processor-based system.

x64

generate 64-bit unified binary code including full optimizations and support for both AMD and Intel x64 processors.

Refer to the PGI Release Notes for a concise list of the features of these processors that distinguish them as separate targets when using the PGI compilers and tools.

The syntax for 64-bit and 32-bit targets is similar, even though the target information varies.

Syntax for 64-bit targets:

```
-tp {k8-64 | k8-64e | p7-64 | core2-64 | x64}
```

Syntax for 32-bit targets:

```
-tp {k8-32 | p6 | p7 | core2 | piii | px}
```

Using `-tp` to Generate a Unified Binary

Different processors have differences, some subtle, in hardware features such as instruction sets and cache size. The compilers make architecture-specific decisions about such things as instruction selection, instruction scheduling, and vectorization. Any of these decisions can have significant effects on performance and compatibility. PGI unified binaries provide a low-overhead means for a single program to run well on a number of hardware platforms.

You can use the `-tp` option to produce PGI Unified Binary programs. The compilers generate, and combine into one executable, multiple binary code streams, each optimized for a specific platform. At runtime, this one executable senses the environment and dynamically selects the appropriate code stream.

The target processor switch, `-tp`, accepts a comma-separated list of 64-bit targets and will generate code optimized for each listed target. For example, the following switch generates optimized code for three targets: k8-64, p7-64, and core2-64.

Syntax for optimizing for multiple targets:

```
-tp k8-64,p7-64,core2-64
```

The `-tp k8-64` and `-tp k8-64e` options result in generation of code supported on and optimized for AMD x64 processors, while the `-tp p7-64` option results in generation of code that is supported on and optimized for Intel x64 processors. Performance of k8-64 or k8-64e code executed on Intel x64 processors, or of p7-64 code executed on AMD x64 processors, can often be significantly less than that obtained with a native binary.

The special `-tp x64` option is equivalent to `-tp k8-64,p7-64`. This switch produces PGI Unified Binary programs containing code streams fully optimized and supported for *both* AMD64 and Intel EM64T processors.

For more information on unified binaries, refer to the section "Processor-Specific Optimization and the Unified Binary" in the PGI Compiler User's Guide.

"Processor-Specific Optimization & the Unified Binary" on page 137.

Related options: `-M<pgflag>` options that control environments

`-[no]traceback`

Adds debug information for runtime traceback for use with the environment variable `PGI_TERM`.

Default: The compiler enables traceback for FORTRAN 77 and Fortran 90/95 and disables traceback for C and C++.

Syntax:

```
-traceback
```

Usage: In this example, `pgfortran` enables traceback for the program `myprog.f`.

```
$ pgfortran -traceback myprog.f
```

Description: Use this option to enable or disable runtime traceback information for use with the environment variable `PGI_TERM`.

Setting `setTRACEBACK=OFF`; in `siterc` or `.mypg*rc` also disables default traceback.

Using `ON` instead of `OFF` enables default traceback.

`-U`

Initializes the symbol-table with `<symbol>`, which is undefined for the linker.

Default: The compiler does not use the `-u` option.

Syntax:

```
-usymbol
```

Where *symbol* is a symbolic name.

Usage: In this example, `pgfortran` initializes symbol-table with `test`.

```
$ pgfortran -utest myprog.f
```

Description: Use this option to initialize the symbol-table with `<symbol>`, which is undefined for the linker. An undefined symbol triggers loading of the first member of an archive library.

Related options: `-c`, `-o`, `-s`

`-U`

Undefines a preprocessor macro.

Syntax:

```
-Usymbol
```

Where *symbol* is a symbolic name.

Usage: The following examples undefine the macro test.

```
$ pgfortran -Utest myprog.F
$ pgfortran -Dtest -Utest myprog.F
```

Description: Use this option to undefine a preprocessor macro. You can also use the `#undef` preprocessor directive to undefine macros.

To set this option in PVE, use the Fortran | Preprocessor | Undefine Preprocessor Definitions property, described in “Undefine Preprocessor Definitions” on page 382.

Related options: `-D`, `-Mnostddef`.

-V[release_number]

Displays additional information, including version messages. Further, if a `release_number` is appended, the compiler driver attempts to compile using the specified release instead of the default release.

Note

There can be no space between `-v` and `release_number`.

Default: The compiler does not display version information and uses the release specified by your path to compile.

Usage: The following command-line shows the output using the `-v` option.

```
% pgfortran -V myprog.f
```

The following command-line causes `pgcc` to compile using the 5.2 release instead of the default release.

```
% pgcc -V5.2 myprog.c
```

Description: Use this option to display additional information, including version messages or, if a `release_number` is appended, to instruct the compiler driver to attempt to compile using the specified release instead of the default release.

The specified release must be co-installed with the default release, and must have a release number greater than or equal to 4.1, which was the first release that supported this functionality.

To set this option in PVE, use the Fortran | General | Display Startup Banner property, described in “Display Startup Banner” on page 375.

Related options: `-Minfo`, `-v`

-V

Displays the invocations of the compiler, assembler, and linker.

Default: The compiler does not display individual phase invocations.

Usage: In the following example you use `-v` to see the commands sent to compiler tools, assembler, and linker.

```
$ pgfortran -v myprog.f90
```

Description: Use the `-v` option to display the invocations of the compiler, assembler, and linker. These invocations are command lines created by the compiler driver from the files and the `-W` options you specify on the compiler command-line.

Related options: `-dryrun`, `-Minfo`, `-V`, `-W`

`-W`

Passes arguments to a specific phase.

Syntax:

```
-W{0 | a | l },option[,option...]
```

Note

You cannot have a space between the `-W` and the single-letter pass identifier, between the identifier and the comma, or between the comma and the option.

0

(the number zero) specifies the compiler.

a

specifies the assembler.

l

(lowercase letter l) specifies the linker.

option

is a string that is passed to and interpreted by the compiler, assembler or linker. Options separated by commas are passed as separate command line arguments.

Usage: In the following example the linker loads the text segment at address `0xffc00000` and the data segment at address `0xffe00000`.

```
$ pgfortran -Wl,-k,-t,0xffc00000,-d,0xffe00000 myprog.f
```

Description: Use this option to pass arguments to a specific phase. You can use the `-W` option to specify options for the assembler, compiler, or linker.

Note

A given PGI compiler command invokes the compiler driver, which parses the command-line, and generates the appropriate commands for the compiler, assembler, and linker.

Related options: `-Minfo`, `-V`, `-v`

–W

Do not print warning messages.

Default: The compiler prints warning messages.

Usage: In the following example no warning messages are printed.

```
$ pgfortran -w myprog.f
```

Description: Use the `–w` option to not print warning messages. Sometimes the compiler issues many warning in which you may have no interest. You can use this option to not issue those warnings.

Related options: `–silent`

–M Options by Category

This section describes each of the options available with `–M` by the categories:

Code generation	Fortran Language Controls	Optimization	Environment
C/C++ Language Controls	Inlining	Miscellaneous	

For a complete alphabetical list of all the options, refer to “`–M Options Summary`” on page 55.

The following sections provide detailed descriptions of several, but not all, of the `–M<pgflag>` options. For a complete alphabetical list of all the options, refer to “`–M Options Summary`” on page 55. These options are grouped according to categories and are listed with exact syntax, defaults, and notes concerning similar or related options.

Code Generation Controls

This section describes the `–M<pgflag>` options that control code generation.

Default: For arguments that you do not specify, the default code generation controls are these:

<code>nodaz</code>	<code>norecursive</code>	<code>nosecond_underscore</code>
<code>noflushz</code>	<code>noreentrant</code>	<code>nostride0</code>
<code>largeaddressaware</code>	<code>noref_externals</code>	<code>signextend</code>

Related options: `–D`, `–I`, `–L`, `–l`, `–U`

The following list provides the syntax for each `–M<pgflag>` option that controls code generation. Each option has a description and, if appropriate, any related options.

–Mdaz

Set IEEE denormalized input values to zero; there is a performance benefit but misleading results can occur, such as when dividing a small normalized number by a denormalized number. To take effect, this option must be set for the main program.

To set this option in PVE, use the Fortran | Floating Point Options | Treat Denormalized Values as Zero property, described in “Treat Denormalized Values as Zero” on page 391.

–Mnodaz

Do not treat denormalized numbers as zero. To take effect, this option must be set for the main program.

–Mnodwarf

Specifies not to add DWARF debug information; must be used in combination with –g.

–Mdwarf1

Generate DWARF1 format debug information; must be used in combination with –g.

–Mdwarf2

Generate DWARF2 format debug information; must be used in combination with –g.

–Mdwarf3

Generate DWARF3 format debug information; must be used in combination with –g.

–Mflushz

Set SSE flush-to-zero mode; if a floating-point underflow occurs, the value is set to zero. To take effect, this option must be set for the main program.

To set this option in PVE, use the Fortran | Floating Point Options | Flush Denormalized Results to Zero property, described in “Flush Denormalized Results to Zero” on page 391.

–Mnoflushz

Do not set SSE flush-to-zero mode; generate underflows. To take effect, this option must be set for the main program.

–Mfunc32

Align functions on 32-byte boundaries.

–Minstrument [=functions] *linux86-64 only*

Generate additional code to enable instrumentation of functions. The option –Minstrument=functions is the same as –Minstrument.

Implies –Minfo=ccff and –Mframe.

–Mlargeaddressaware=[no]

[Win64 only] Generates code that allows for addresses greater than 2GB, using RIP-relative addressing.

Use –Mlargeaddressaware=no for a direct addressing mechanism that restricts the total addressable memory.

Note

Do not use –Mlargeaddressaware=no if the object file will be placed in a DLL.

If –Mlargeaddressaware=no is used to compile any object file, it must also be used when linking.

–Mlarge_arrays

Enable support for 64-bit indexing and single static data objects larger than 2GB in size. This option is default in the presence of –mmodel=medium. Can be used separately together with the default small memory model for certain 64-bit applications that manage their own memory space. For more

information, refer to the “Programming Considerations for 64-Bit Environments” chapter of the PGI Compiler User’s Guide.

`-Mmpi=option`

`-Mmpi` adds the include and library options to the compile and link commands necessary to build an MPI application using MPI header files and libraries.

To use `-Mmpi`, you must have a version of MPI installed on your system.

This option tells the compiler to use the headers and libraries for the specified version of MPI.

On Windows, PGI compilers and tools support Microsoft’s implementation of MPI, MSMPI. This version of MPI is available with Microsoft’s HPC Pack 2008 SDK (RTM/SP1/SP2) or HPC Pack 2008 R2 MS-MPI Redistributable Package (SP3/SP4).

`-Mmpi=msmpi` - Select Microsoft MPI libraries.

For more information on these options, refer to the chapter “Using MPI in PVF in the PGI Compiler User’s Guide.

Note

On Windows, the user can set the environment variables `MSMPIINC`, `MS`, either `MSMPIINC`, `MSMPILIB32`, and `MSMPILIB64` to override the default location for the directory associated with using `MSMPI`.

`-Mnolarge_arrays`

Disable support for 64-bit indexing and single static data objects larger than 2GB in size. When placed after `-mcmodel=medium` on the command line, disables use of 64-bit indexing for applications that have no single data object larger than 2GB.

`-Mnomain`

Instructs the compiler not to include the object file that calls the Fortran main program as part of the link step. This option is useful for linking programs in which the main program is written in C/C++ and one or more subroutines are written in Fortran (`pgf77`, `pgf95`, `pgfortran`, and `pghpf` only).

`-M[no]movnt`

Instructs the compiler to generate nontemporal move and prefetch instructions even in cases where the compiler cannot determine statically at compile-time that these instructions will be beneficial.

`-M[no]pre`

enables or disables partial redundancy elimination.

`-Mprof[=option[,option,...]]`

Set performance profiling options. Use of these options causes the resulting executable to create a performance profile that can be viewed and analyzed with the *PGPROF* performance profiler. In the descriptions that follow, PGI-style profiling implies compiler-generated source instrumentation. MPICH-style profiling implies the use of instrumented wrappers for MPI library routines.

The option argument can be any of the following:

`[no]ccff`

Enable [disable] common compiler feedback format, CCFF, information.

`dwarf`

Generate limited DWARF symbol information sufficient for most performance profilers.

`func`

Perform PGI-style function-level profiling.

`lines`

Perform PGI-style line-level profiling.

`mmpi`

Perform MPICH-style profiling for Microsoft MPI. Implies `-Mmpi=mmpi`.

This option is valid only if the MSMPI components are installed.

For more information, refer to the section “Using MPI in PVF” in the PVF User’s Guide.

To set this option in PVF, use the Fortran | General | Profiling property, described in “Line-Level Profiling” on page 407. To enable profiling you must also set the Linker | General | Profiling property, described in “Line-Level Profiling” on page 407.

–`Mrecursive`

instructs the compiler to allow Fortran subprograms to be called recursively.

–`Mnorecursive`

Fortran subprograms may not be called recursively.

–`Mref_externals`

force references to names appearing in EXTERNAL statements .

–`Mnoref_externals`

do not force references to names appearing in EXTERNAL statements (pgf77, pgf95, pgfortran, and pghpf only).

–`Mreentrant`

instructs the compiler to avoid optimizations that can prevent code from being reentrant.

–`Mnoreentrant`

instructs the compiler not to avoid optimizations that can prevent code from being reentrant.

–`Msecond_underscore`

instructs the compiler to add a second underscore to the name of a Fortran global symbol if its name already contains an underscore. This option is useful for maintaining compatibility with object code compiled using g77, which uses this convention by default.

–`Mnosecond_underscore`

instructs the compiler not to add a second underscore to the name of a Fortran global symbol if its name already contains an underscore.

–`Msignextend`

instructs the compiler to extend the sign bit that is set as a result of converting an object of one data type to an object of a larger signed data type.

- Mnosignextend**
instructs the compiler not to extend the sign bit that is set as the result of converting an object of one data type to an object of a larger data type.
- Msafe_lastval**
When a scalar is used after a loop, but is not defined on every iteration of the loop, the compiler does not by default parallelize the loop. However, this option tells the compiler it's safe to parallelize the loop. For a given loop the last value computed for all scalars makes it safe to parallelize the loop.
- Mstride0**
instructs the compiler to inhibit certain optimizations and to allow for stride 0 array references. This option may degrade performance and should only be used if zero-stride induction variables are possible.
- Mnostride0**
instructs the compiler to perform certain optimizations and to disallow for stride 0 array references.
- Munix**
use UNIX symbol and parameter passing conventions for Fortran subprograms.
- Mvarargs**
force Fortran program units to assume procedure calls are to C functions with a varargs-type interface.

Environment Controls

This section describes the –M<pgflag> options that control environments.

Default: For arguments that you do not specify, the default environment option depends on your configuration.

The following list provides the syntax for each –M<pgflag> option that controls environments. Each option has a description and, if appropriate, a list of any related options.

- Mnostartup**
instructs the linker not to link in the standard startup routine that contains the entry point (`_start`) for the program.

Note

If you use the –Mnostartup option and do not supply an entry point, the linker issues the following error message: Warning: cannot find entry symbol `_start`

- M[no]smartalloc [=huge | h[uge:<n> | hugebss | nohuge]**
adds a call to the routine `mallopt` in the main routine. This option supports large TLBs on Linux and Windows. This option must be used to compile the main routine to enable optimized malloc routines.

The option arguments can be any of the following:

huge

Link in the huge page runtime library.

Enables large 2-megabyte pages to be allocated. The effect is to reduce the number of TLB entries required to execute a program. This option is most effective on Barcelona and Core 2 systems; older

architectures do not have enough TLB entries for this option to be beneficial. By itself, the huge suboption tries to allocate as many huge pages as required.

huge:<n>

Link the huge page runtime library and allocate *n* huge pages. Use this suboption to limit the number of huge pages allocated to *n*.

You can also limit the pages allocated by using the environment variable `PGI_HUGE_PAGES`.

hugebss

(64-bit only) Puts the BSS section in huge pages; attempts to put a program's uninitialized data section into huge pages.

Note

This flag dynamically links the library `libhugetlbfs_pgi` even if `-Bstatic` is used.

nohuge

Overrides a previous `-Msmartalloc=huge` setting.

Tip

To be effective, this switch must be specified when compiling the file containing the Fortran, C, or C++ main program.

–Mnostdinc

instructs the compiler to not search the standard location for include files. To set this option in PVE, use the Fortran | Preprocessor | Ignore Standard Include Path property, described in “Ignore Standard Include Path” on page 381.

–Mnostdlib

instructs the linker not to link in the standard libraries in the library directory `lib` within the standard directory. You can link in your own library with the `-l` option or specify a library directory with the `-L` option.

Fortran Language Controls

This section describes the `–M<pgflag>` options that affect Fortran language interpretations by the PGI Fortran compilers. These options are valid only for the `pgf77`, `pgf95`, and `pgfortran` compiler drivers.

Default: For arguments that you do not specify, the defaults are as follows:

backslash	nodefaultunit	dollar,_	noonetrip	nounixlogical
nodclchk	nodlines	noiomutex	nosave	noupcase

The following list provides the syntax for each `–M<pgflag>` option that affect Fortran language interpretations. Each option has a description and, if appropriate, a list of any related options.

–**Mallocatable=95|03**

controls whether Fortran 95 or Fortran 2003 semantics are used in allocatable array assignments. The default behavior is to use Fortran 95 semantics; the 03 option instructs the compiler to use Fortran 2003 semantics.

–**Mbackslash**

the compiler treats the backslash as a normal character, and not as an escape character in quoted strings.

–**Mnobackslash**

the compiler recognizes a backslash as an escape character in quoted strings (in accordance with standard C usage).

–**Mcuda**

the compiler enables Cuda Fortran.

The following suboptions exist:

Note

If more than one option is on the command line, all the specified options occur.

cc10

Generate code for compute capability 1.0.

cc11

Generate code for compute capability 1.1.

cc12

Generate code for compute capability 1.2.

cc13

Generate code for compute capability 1.3.

cc20

Generate code for compute capability 2.0.

cc30

Generate code for compute capability 3.0.

cuda2.3 or 2.3

Sets the toolkit compatibility version to 2.3.

cuda3.0 or 3.0

Sets the toolkit compatibility version to 3.0.

cuda3.1 or 3.1

Sets the toolkit compatibility version to 3.1.

cuda3.2 or 3.2

Sets the toolkit compatibility version to 3.2.

cuda4.0 or 4.0

Sets the toolkit compatibility version to 4.0.

cuda4.1 or 4.1

Sets the toolkit compatibility version to 4.1. This is the default.

cuda4.2 or 4.2

Sets the toolkit compatibility version to 4.2.

Note

Compiling with the CUDA 3.1, CUDA 3.2, CUDA 4.0, CUDA 4.1, or CUDA 4.2 toolkit, either by using the `-ta=nvidia:cuda3.1`, `-ta=nvidia:cuda3.2`, `-ta=nvidia:cuda4.0`, `-ta=nvidia:cuda4.1`, or `-ta=nvidia:cuda4.2` option or by adding `set CUDAVERSION=3.1`, `set CUDAVERSION=3.2`, `set CUDAVERSION=4.0`, `set CUDAVERSION=4.1`, or `set CUDAVERSION=4.2` to the `siterc` file, generates binaries that may not work on machines with a 2.3 CUDA driver.

`pgaccelinfo` prints the driver version as the first line of output.

For a 2.3 driver: `CUDA Driver Version 2030`

For a 3.0 driver: `CUDA Driver Version 3000`

For a 3.1 driver: `CUDA Driver Version 3010`

For a 3.2 driver: `CUDA Driver Version 3020`

For a 4.0 driver: `CUDA Driver Version 4000`

For a 4.1 driver: `CUDA Driver Version 4010`

For a 4.2 driver: `CUDA Driver Version 4020`

emu

Enable Cuda Fortran emulation mode.

fastmath

Use routines from the fast math library.

[no]flushz

Enable[disable] flush-to-zero mode for floating point computations in the GPU code generated for CUDA Fortran kernels.

keepbin

Keep the generated binary (.bin) file for CUDA Fortran.

keepgpu

Keep the generated GPU code for CUDA Fortran.

keepptx

Keep the portable assembly (.ptx) file for the GPU code.

maxregcount:n

Specify the maximum number of registers to use on the GPU. Leaving this blank indicates no limit.

nofma

Do not generate fused multiply-add instructions.

ptxinfo

Show PTXAS informational messages during compilation.

- `-Mdcchk`
the compiler requires that all program variables be declared.
- `-Mnodchk`
the compiler does not require that all program variables be declared.
- `-Mdefaultunit`
the compiler treats "*" as a synonym for standard input for reading and standard output for writing.
- `-Mnodefaultunit`
the compiler treats "*" as a synonym for unit 5 on input and unit 6 on output.
- `-Mdlines`
the compiler treats lines containing "D" in column 1 as executable statements (ignoring the "D").
- `-Mnodlines`
the compiler does not treat lines containing "D" in column 1 as executable statements (does not ignore the "D").
- `-Mdollar, char`
char specifies the character to which the compiler maps the dollar sign. The compiler allows the dollar sign in names.
- `-Mextend`
the compiler accepts 132-column source code; otherwise it accepts 72-column code.
- `-Mfixed`
the compiler assumes input source files are in FORTRAN 77-style fixed form format.
- `-Mfree`
the compiler assumes the input source files are in Fortran 90/95 freeform format.
- `-Miomutex`
the compiler generates critical section calls around Fortran I/O statements.
- `-Mnoiomutex`
the compiler does not generate critical section calls around Fortran I/O statements.
- `-Monetrip`
the compiler forces each DO loop to execute at least once.
- `-Mnoonetrip`
the compiler does not force each DO loop to execute at least once. This option is useful for programs written for earlier versions of Fortran.
- `-Msave`
the compiler assumes that all local variables are subject to the SAVE statement. Note that this may allow older Fortran programs to run, but it can greatly reduce performance.
- `-Mnosave`
the compiler does not assume that all local variables are subject to the SAVE statement.
- `-Mstandard`
the compiler flags non-ANSI-conforming source code.

–Munixlogical

directs the compiler to treat logical values as true if the value is non-zero and false if the value is zero (UNIX F77 convention.) When –Munixlogical is enabled, a logical value or test that is non-zero is .TRUE., and a value or test that is zero is .FALSE.. In addition, the value of a logical expression is guaranteed to be one (1) when the result is .TRUE..

–Mnunixlogical

directs the compiler to use the VMS convention for logical values for true and false. Even values are true and odd values are false.

–Mupcase

the compiler preserves uppercase letters in identifiers. With –Mupcase, the identifiers "X" and "x" are different. Keywords must be in lower case. This selection affects the linking process. If you compile and link the same source code using –Mupcase on one occasion and –Mnoupcase on another, you may get two different executables - depending on whether the source contains uppercase letters. The standard libraries are compiled using the default –Mnoupcase .

–Mnoupcase

the compiler converts all identifiers to lower case. This selection affects the linking process: If you compile and link the same source code using –Mupcase on one occasion and –Mnoupcase on another, you may get two different executables (depending on whether the source contains uppercase letters). The standard libraries are compiled using –Mnoupcase.

Inlining Controls

This section describes the –M<pgflag> options that control function inlining. Before looking at all the options, let's look at a couple examples.

Usage: In the following example, the compiler extracts functions that have 500 or fewer statements from the source file `myprog.f` and saves them in the file `extract.il`.

```
$ pgfortran -Mextract=500 -o extract.il myprog.f
```

In the following example, the compiler inlines functions with fewer than approximately 100 statements in the source file `myprog.f`.

```
$ pgfortran -Minline=size:100 myprog.f
```

Related options: –o, –Mextract

The following list provides the syntax for each –M<pgflag> option that controls function inlining. Each option has a description and, if appropriate, a list of any related options.

–M[no]autoinline[=option[,option,...]]

instructs the compiler to inline [not to inline] a C/C++ function at –O2, where the option can be any of these:

levels:n

instructs the compiler to perform *n* levels of inlining. The default number of levels is 10.

maxsize:n

instructs the compiler not to inline functions of size > *n*. The default size is 100.

`totalsize:n`

instructs the compiler to stop inlining when the size equals *n*. The default size is 800.

`-Mextract[=option[,option,...]]`

Extracts functions from the file indicated on the command line and creates or appends to the specified extract directory where option can be any of:

`name:func`

instructs the extractor to extract function `func` from the file.

`size:number`

instructs the extractor to extract functions with number or fewer statements from the file.

`lib:filename.ext`

Use directory `filename.ext` as the extract directory (required in order to save and re-use inline libraries).

If you specify both name and size, the compiler extracts functions that match `func`, or that have number or fewer statements. For examples of extracting functions, refer to “Using Function Inlining” in the PGI Compiler User’s Guide.

`-Minline[=option[,option,...]]`

This passes options to the function inliner, where the option can be any of these:

`except:func`

instructs the inliner to inline all eligible functions except `func`, a function in the source text. Multiple functions can be listed, comma-separated.

`[name:]func`

instructs the inliner to inline the function `func`. The `func` name should be a non-numeric string that does not contain a period. You can also use a `name:` prefix followed by the function name. If `name:` is specified, what follows is always the name of a function.

`[lib:]filename.ext`

instructs the inliner to inline the functions within the library file `filename.ext`. The compiler assumes that a `filename.ext` option containing a period is a library file. Create the library file using the `-Mextract` option. You can also use a `lib:` prefix followed by the library name. If `lib:` is specified, no period is necessary in the library name. Functions from the specified library are inlined. If no library is specified, functions are extracted from a temporary library created during an extract prepass.

`levels:number`

instructs the inliner to perform number levels of inlining. The default number is 1.

`[no]reshape`

instructs the inliner to allow (disallow) inlining in Fortran even when array shapes do not match. The default is `-Minline=noreshape`, except with `-Mconcur` or `-mp`, where the default is `-Minline=reshape,=reshape`.

`[size:]number`

instructs the inliner to inline functions with number or fewer statements. You can also use a `size:` prefix followed by a number. If `size:` is specified, what follows is always taken as a number.

If you specify both `func` and `number`, the compiler inlines functions that match the function name or have number or fewer statements. For examples of inlining functions, refer to “Using Function Inlining” in the PGI Compiler User’s Guide.

To set this option in PVF, use the Fortran | Optimization | Inlining property, described in “Inlining” on page 379.

Optimization Controls

This section describes the `–M<pgflag>` options that control optimization. Before looking at all the options, let’s look at the defaults.

Default: For arguments that you do not specify, the default optimization control options are as follows:

<code>depchk</code>	<code>noipa</code>	<code>nounroll</code>	<code>nor8</code>
<code>i4</code>	<code>nolre</code>	<code>novect</code>	<code>nor8intrinsic</code>
<code>nofprelaxed</code>	<code>noprefetch</code>		

Note

If you do not supply an option to `–Mvect`, the compiler uses defaults that are dependent upon the target system.

Usage: In this example, the compiler invokes the vectorizer with use of packed SSE instructions enabled.

```
$ pgfortran -Mvect=sse -Mcache_align myprog.f
```

Related options: `–g`, `–O`

The following list provides the syntax for each `–M<pgflag>` option that controls optimization. Each option has a description and, if appropriate, a list of any related options.

`–Mcache_align`

Align unconstrained objects of length greater than or equal to 16 bytes on cache-line boundaries. An unconstrained object is a data object that is not a member of an aggregate structure or common block. This option does not affect the alignment of allocatable or automatic arrays.

Note

To effect cache-line alignment of stack-based local variables, the main program or function must be compiled with `–Mcache_align`.

`–Mconcur [=option [,option,...]]`

Instructs the compiler to enable auto-concurrentization of loops. If `–Mconcur` is specified, multiple processors will be used to execute loops that the compiler determines to be parallelizable. Where option is one of the following:

`allcores`

Instructs the compiler to use all available cores. Use this option at link time.

[no]altcode:n

Instructs the parallelizer to generate alternate serial code for parallelized loops. If altcode is specified without arguments, the parallelizer determines an appropriate cutoff length and generates serial code to be executed whenever the loop count is less than or equal to that length. If altcode:n is specified, the serial altcode is executed whenever the loop count is less than or equal to n. If noaltcode is specified, the parallelized version of the loop is always executed regardless of the loop count.

bind

Instructs the parallelizer to bind threads to cores. Use this option at link time.

cncall

Calls in parallel loops are safe to parallelize. Loops containing calls are candidates for parallelization. Also, no minimum loop count threshold must be satisfied before parallelization will occur, and last values of scalars are assumed to be safe.

dist:block

Parallelize with block distribution (this is the default). Contiguous blocks of iterations of a parallelizable loop are assigned to the available processors.

dist:cyclic

Parallelize with cyclic distribution. The outermost parallelizable loop in any loop nest is parallelized. If a parallelized loop is innermost, its iterations are allocated to processors cyclically. For example, if there are 3 processors executing a loop, processor 0 performs iterations 0, 3, 6, etc.; processor 1 performs iterations 1, 4, 7, etc.; and processor 2 performs iterations 2, 5, 8, etc.

[no]innermost

Enable parallelization of innermost loops. The default is to not parallelize innermost loops, since it is usually not profitable on dual-core processors.

noassoc

Disables parallelization of loops with reductions.

When linking, the `-Mconcur` switch must be specified or unresolved references will result. The `NCPUS` environment variable controls how many processors or cores are used to execute parallelized loops.

To set this option in PVE, use the Fortran | Optimization | Auto-Parallelization property, described in “Auto-Parallelization” on page 380.

Note

This option applies only on shared-memory multi-processor (SMP) or multi-core processor-based systems.

-Mcray[=option[,option,...]]

Force Cray Fortran (CF77) compatibility with respect to the listed options. Possible values of option include:

pointer

for purposes of optimization, it is assumed that pointer-based variables do not overlay the storage of any other variable.

–Mdepchk

instructs the compiler to assume unresolved data dependencies actually conflict.

–Mnodepchk

Instructs the compiler to assume potential data dependencies do not conflict. However, if data dependencies exist, this option can produce incorrect code.

–Mdse

Enables a dead store elimination phase that is useful for programs that rely on extensive use of inline function calls for performance. This is disabled by default.

–Mnodse

Disables the dead store elimination phase. This is the default.

–M[no] fpapprox [=option]

Perform certain fp operations using low-precision approximation.

–Mnofpapprox specifies not to use low-precision fp approximation operations.

By default –Mfpapprox is not used.

If –Mfpapprox is used without suboptions, it defaults to use approximate `div`, `sqrt`, and `rsqrt`. The available suboptions are these:

`div`

Approximate floating point division

`sqrt`

Approximate floating point square root

`rsqrt`

Approximate floating point reciprocal square root

–M[no] fpmisalign

Instructs the compiler to allow (not allow) vector arithmetic instructions with memory operands that are not aligned on 16-byte boundaries. The default is –Mnofpalign on all processors.

Note

Applicable only with one of these options: –tp barcelona or –tp barcelona-64

–M[no] fprelaxed [=option]

Instructs the compiler to use (not use) relaxed precision in the calculation of some intrinsic functions. Can result in improved performance at the expense of numerical accuracy.

To set this option in PVE, use the Fortran | Floating Point Options | Floating Point Consistency property. For more information on this property, refer to “Floating Point Consistency” on page 390.

The possible values for option are:

`div`

Perform divide using relaxed precision.

`noorder`

Do not allow expression reordering or factoring.

`order`

Allow expression reordering, including factoring.

`recip`

Perform reciprocal using relaxed precision.

`rsqrt`

Perform reciprocal square root (1/sqrt) using relaxed precision.

`sqrt`

Perform square root with relaxed precision.

With no options, `-Mfprelaxed` generates relaxed precision code for those operations that generate a significant performance improvement, depending on the target processor.

The default is `-Mnofprelaxed` which instructs the compiler to not use relaxed precision in the calculation of intrinsic functions.

`-Mi4`

the compiler treats INTEGER variables as INTEGER*4.

`-Mipa=<option>[,<option>[,...]]`

Pass options to the interprocedural analyzer.

Note

`-Mipa` implies `-O2`, and the minimum optimization level that can be specified in combination with `-Mipa` is `-O2`.

For example, if you specify `-Mipa -O1` on the command line, the optimization level is automatically elevated to `-O2` by the compiler driver. Typically, as recommended, you would use `-Mipa=fast`.

Many of the following suboptions can be prefaced with `no`, which reverses or disables the effect of the suboption if it's included in an aggregate suboption such as `-Mipa=fast`. The choices of option are:

`[no]align`

recognize when targets of a pointer dummy are aligned. The default is `noalign`.

`[no]arg`

remove arguments replaced by `const`, `ptr`. The default is `noarg`.

`[no]cg`

generate call graph information for viewing using the `pgicg` command-line utility. The default is `nocg`.

`[no]const`

perform interprocedural constant propagation. The default is `const`.

except:<func>

used with `inline` to specify functions which should not be inlined. The default is to inline all eligible functions according to internally defined heuristics. Valid only immediately following the `inline` suboption.

[no]f90ptr

F90/F95 pointer disambiguation across calls. The default is `nof90ptr`.

fast

choose IPA options generally optimal for the target. To see settings for `-Mipa=fast` on a given target, use `-help`.

force

force all objects to re-compile regardless of whether IPA information has changed.

[no]globals

optimize references to global variables. The default is `noglobals`.

inline[:n]

perform automatic function inlining. If the optional `:n` is provided, limit inlining to at most `n` levels. IPA-based function inlining is performed from leaf routines upward.

ipofile

save IPA information in an `.ipo` file rather than incorporating it into the object file.

jobs[:n]

recompile `n` jobs in parallel and print source file names as they are compiled.

[no]keepobj

keep the optimized object files, using file name mangling, to reduce re-compile time in subsequent builds. The default is `keepobj`.

[no]libc

optimize calls to certain standard C library routines. The default is `nolibc`.

[no]libinline

allow inlining of routines from libraries; implies `-Mipa=inline`. The default is `nolibinline`.

[no]libopt

allow recompiling and optimization of routines from libraries using IPA information. The default is `nolibopt`.

[no]localarg

equivalent to `arg` plus externalization of local pointer targets. The default is `nolocalarg`.

main:<func>

specify a function to appear as a global entry point; may appear multiple times; disables linking.

rsqrt

Perform reciprocal square root ($1/\sqrt{x}$) using relaxed precision.

[no]pfo

enable profile feedback information. The nopfo option is valid only immediately following the inline suboption. `-Mipa=inline,nopfo` tells IPA to ignore PFO information when deciding what functions to inline, if PFO information is available.

[no]ptr

enable pointer disambiguation across procedure calls. The default is noptr.

[no]pure

pure function detection. The default is nopure.

required

return an error condition if IPA is inhibited for any reason, rather than the default behavior of linking without IPA optimization.

[no]reshape

enables or disables Fortran inline with mismatched array shapes. Valid only immediately following the inline suboption.

safe:[<function>|<library>]

declares that the named function, or all functions in the named library, are safe; a safe procedure does not call back into the known procedures and does not change any known global variables.

Without `-Mipa=safe`, any unknown procedures will cause IPA to fail.

[no]safeall

declares that all unknown procedures are safe; see `-Mipa=safe`. The default is nosafeall.

[no]shape

perform Fortran 90 array shape propagation. The default is noshape.

summary

only collect IPA summary information when compiling; this prevents IPA optimization of this file, but allows optimization for other files linked with this file.

[no]vestigial

remove uncalled (vestigial) functions. The default is novestigial.

If you use `-Mipa=vestigial` in combination with `-Mipa=libopt` with PGCC, you may encounter unresolved references at link time. This problem is due to the erroneous removal of functions by the vestigial sub-option to `-Mipa`. You can work around this problem by listing specific sub-options to `-Mipa`, not including vestigial.

`-M` [no] loop32

Aligns or does not align innermost loops on 32 byte boundaries with `-tp barcelona`.

Small loops on barcelona may run fast if aligned on 32-byte boundaries; however, in practice, most assemblers do not yet implement efficient padding causing some programs to run more slowly with this default. Use `-Mloop32` on systems with an assembler tuned for barcelona. The default is `-Mnoloop32`.

`-Mlre`[=array | assoc | noassoc]

Enables loop-carried redundancy elimination, an optimization that can reduce the number of arithmetic operations and memory references in loops.

array

treat individual array element references as candidates for possible loop-carried redundancy elimination. The default is to eliminate only redundant expressions involving two or more operands.

assoc

allow expression re-association; specifying this suboption can increase opportunities for loop-carried redundancy elimination but may alter numerical results.

noassoc

disallow expression re-association.

–Mnolre

Disables loop-carried redundancy elimination.

–Mnoframe

Eliminates operations that set up a true stack frame pointer for every function. With this option enabled, you cannot perform a traceback on the generated code and you cannot access local variables.

To set this option in PVE, use the Fortran | Optimization | Use Frame Pointer property, described in “Use Frame Pointer” on page 379.

–Mnoi4

the compiler treats INTEGER variables as INTEGER*2.

–Mpfi[=indirect]

generate profile-feedback instrumentation; this includes extra code to collect run-time statistics and dump them to a trace file for use in a subsequent compilation.

When you use the indirect option, `–Mpfi=indirect` saves indirect function call targets.

`–Mpfi` must also appear when the program is linked. When the resulting program is executed, a profile feedback trace file `pgfi.out` is generated in the current working directory; see `–Mpfo`.

Note

Compiling and linking with `–Mpfi` adds significant runtime overhead to almost any executable. You should use executables compiled with `–Mpfi` only for execution of training runs.

–Mpfo[=indirect | nolayout]

enable profile-feedback optimizations; requires the presence of a `pgfi.out` profile-feedback trace file in the current working directory. See `–Mpfi`.

indirect

enable indirect function call inlining

nolayout

disable dynamic code layout.

–Mpre

enables partial redundancy elimination.

–Mpfetch[=option [,option...]]

enables generation of prefetch instructions on processors where they are supported. Possible values for option include:

- d:m**
set the fetch-ahead distance for prefetch instructions to m cache lines.
- n:p**
set the maximum number of prefetch instructions to generate for a given loop to p.
- nta**
use the prefetch instruction.
- plain**
use the prefetch instruction (default).
- t0**
use the prefetcht0 instruction.
- w**
use the AMD-specific prefetchw instruction.
- Mnoprefetch**
Disables generation of prefetch instructions.
- M[no]propcond**
Enables or disables constant propagation from assertions derived from equality conditionals.

The default is enabled.
- Mr8**
the compiler promotes REAL variables and constants to DOUBLE PRECISION variables and constants, respectively. DOUBLE PRECISION elements are 8 bytes in length.
- Mnor8**
the compiler does not promote REAL variables and constants to DOUBLE PRECISION. REAL variables will be single precision (4 bytes in length).
- Mr8intrinsics**
the compiler treats the intrinsics CMPLX and REAL as DCMPLX and DBLE, respectively.
- Mnor8intrinsics**
the compiler does not promote the intrinsics CMPLX and REAL to DCMPLX and DBLE, respectively.
- Mscalarsse**
Use SSE/SSE2 instructions to perform scalar floating-point arithmetic. (This option is valid only on option `-tp {p7 | k8-32 | k8-64}` targets).
- Mnoscalarsse**
Do not use SSE/SSE2 instructions to perform scalar floating-point arithmetic; use x87 instructions instead. (This option is not valid in combination with the `-tp k8-64` option).
- Msmart**
instructs the compiler driver to invoke a post-pass assembly optimization utility.
- Mnosmart**
instructs the compiler not to invoke an AMD64-specific post-pass assembly optimization utility.

`–Munroll [=option [,option...]]`

invokes the loop unroller to execute multiple instances of the loop during each iteration. This also sets the optimization level to 2 if the level is set to less than 2, or if no `–O` or `–g` options are supplied. The option is one of the following:

`c:m`

instructs the compiler to completely unroll loops with a constant loop count less than or equal to `m`, a supplied constant. If this value is not supplied, the `m` count is set to 4.

`m:<n>`

instructs the compiler to unroll multi-block loops `n` times. This option is useful for loops that have conditional statements. If `n` is not supplied, then the default value is 4. The default setting is not to enable `–Munroll=m`.

`n:<n>`

instructs the compiler to unroll single-block loops `n` times, a loop that is not completely unrolled, or has a non-constant loop count. If `n` is not supplied, the unroller computes the number of times a candidate loop is unrolled.

To set this option in PVE, use the Fortran | Optimization | Loop Unroll Count property, described in “Loop Unroll Count” on page 379.

`–Mnounroll`

instructs the compiler not to unroll loops.

`–M[no]vect [=option [,option,...]]`

(disable) enable the code vectorizer, where option is one of the following:

`altcode`

Instructs the vectorizer to generate alternate code (altcode) for vectorized loops when appropriate. For each vectorized loop the compiler decides whether to generate altcode and what type or types to generate, which may be any or all of: altcode without iteration peeling, altcode with non-temporal stores and other data cache optimizations, and altcode based on array alignments calculated dynamically at runtime. The compiler also determines suitable loop count and array alignment conditions for executing the altcode. This option is enabled by default.

`noaltcode`

This disables alternate code generation for vectorized loops.

`assoc`

Instructs the vectorizer to enable certain associativity conversions that can change the results of a computation due to roundoff error. A typical optimization is to change an arithmetic operation to an arithmetic operation that is mathematically correct, but can be computationally different, due to round-off error

`noassoc`

Instructs the vectorizer to disable associativity conversions.

`cachesize:n`

Instructs the vectorizer, when performing cache tiling optimizations, to assume a cache size of `n`. The default is set per processor type, either using the `–tp` switch or auto-detected from the host computer.

[no]gather

Vectorize loops containing indirect array references, such as this one:

```
sum = 0.d0
do k=d(j),d(j+1)-1
  sum = sum + a(k)*b(c(k))
enddo
```

The default is gather.

partial

Instructs the vectorizer to enable partial loop vectorization through innemost loop distribution.

prefetch

Instructs the vectorizer to search for vectorizable loops and, wherever possible, make use of prefetch instructions.

[no]short

Enable [disable] short vector operations. `-Mvect=short` enables generation of packed SSE instructions for short vector operations that arise from scalar code outside of loops or within the body of a loop iteration.

[no]sizelimit

Generate vector code for all loops where possible regardless of the number of statements in the loop. This overrides a heuristic in the vectorizer that ordinarily prevents vectorization of loops with a number of statements that exceeds a certain threshold. The default is `nosizelimit`.

smallvect[:n]

Instructs the vectorizer to assume that the maximum vector length is less than or equal to `n`. The vectorizer uses this information to eliminate generation of the stripmine loop for vectorized loops wherever possible. If the size `n` is omitted, the default is 100.

Note

No space is allowed on either side of the colon (:).

[no]sse

Instructs the vectorizer to search for vectorizable loops and, wherever possible, make use of SSE, SSE2, and prefetch instructions. The default is `nosse`.

[no]uniform

Instructs the vectorizer to perform the same optimizations in the vectorized and residual loops.

Note

This option may affect the performance of the residual loop.

To set this option in PVE, use the Fortran | Optimization Vectorization property, described in “Vectorization” on page 379.

-Mnovect

instructs the compiler not to perform vectorization; can be used to override a previous instance of `-Mvect` on the command-line, in particular for cases in which `-Mvect` is included in an aggregate option such as `-fastsse`.

–Mvect=[*option*]

instructs the compiler to enable loop vectorization, where *option* is one of the following:

partial

Enable partial loop vectorization through innermost loop distribution.

[no]short

Enable [disable] short vector operations. Enables [disables] generation of packed SSE instructions for short vector operations that arise from scalar code outside of loops or within the body of a loop iteration.

simd[:{128|256}]

Specifies to vectorize using SIMD instructions and data, either 128 bits or 256 bits wide, on processors where there is a choice.

tile

Enable tiling/blocking over multiple nested loops for more efficient cache utilization.

–Mnovintr

instructs the compiler not to perform idiom recognition or introduce calls to hand-optimized vector functions.

Miscellaneous Controls

Default: For arguments that you do not specify, the default miscellaneous options are as follows:

inform nobounds nolist warn

Usage: In the following example, the compiler includes Fortran source code with the assembly code.

```
$ pgfortran -Manno -S myprog.f
```

In the following example, the assembler does not delete the assembly file `myprog.s` after the assembly pass.

```
$ pgfortran -Mkeepasm myprog.f
```

In the following example, the compiler displays information about inlined functions with fewer than approximately 20 source lines in the source file `myprog.f`.

```
$ pgfortran -Minfo=inline -Minline=20 myprog.f
```

In the following example, the compiler creates the listing file `myprog.lst`.

```
$ pgfortran -Mlist myprog.f
```

In the following example, array bounds checking is enabled.

```
$ pgfortran -Mbounds myprog.f
```

Related options: –m, –S, –V, –v

The following list provides the syntax for each miscellaneous –M<pgflag> option. Each option has a description and, if appropriate, a list of any related options.

-Manno

annotate the generated assembly code with source code. Implies `-Mkeepasm`.

To set this option in PVE, use the Fortran | Output | Annotated ASM Listing property, described in “Annotate Assembly” on page 404

-Mbounds

enables array bounds checking. If an array is an assumed size array, the bounds checking only applies to the lower bound. If an array bounds violation occurs during execution, an error message describing the error is printed and the program terminates. The text of the error message includes the name of the array, the location where the error occurred (the source file and the line number in the source), and information about the out of bounds subscript (its value, its lower and upper bounds, and its dimension). The following is a sample error message:

```
PGFTN-F-Subscript out of range for array a (a.f: 2)
subscript=3, lower bound=1, upper bound=2, dimension=2
```

-Mnobounds

disables array bounds checking.

-Mbyteswapio

swap byte-order from big-endian to little-endian or vice versa upon input/output of Fortran unformatted data files.

-Mchkfpstk (32-bit only)

instructs the compiler to check for internal consistency of the x87 floating-point stack in the prologue of a function and after returning from a function or subroutine call. Floating-point stack corruption may occur in many ways, one of which is Fortran code calling floating-point functions as subroutines (i.e., with the `CALL` statement). If the `PGI_CONTINUE` environment variable is set upon execution of a program compiled with `-Mchkfpstk`, the stack will be automatically cleaned up and execution will continue. There is a performance penalty associated with the stack cleanup. If `PGI_CONTINUE` is set to verbose, the stack will be automatically cleaned up and execution will continue after printing the warning message.

Note

This switch is only valid for 32-bit. On 64-bit it is ignored.

-Mchkptr

instructs the compiler to check for pointers that are dereferenced while initialized to `NULL`.

-Mchkstk

instructs the compiler to check the stack for available space in the prologue of a function and before the start of a parallel region. Prints a warning message and aborts the program gracefully if stack space is insufficient. Useful when many local and private variables are declared in an OpenMP program.

If the user also sets the `PGI_STACK_USAGE` environment variable to any value, then the program displays the stack space allocated and used after the program exits. For example, you might see something similar to the following message:

```
thread 0 stack: max 8180KB, used 48KB
```

This message indicates that the program used 48KB of a 8180KB allocated stack. For more information on the `PGI_STACK_USAGE`, refer to “`PGI_STACK_USAGE`” in the PGI Compiler User’s Guide.

This information is useful when you want to explicitly set a reserved and committed stack size for your programs, such as using the `-stack` option on Windows.

–Mcpp[=option [,option,...]]

run the PGI cpp-like preprocessor without execution of any subsequent compilation steps. This option is useful for generating dependence information to be included in makefiles.

Note

Only one of the `m`, `md`, `mm` or `mmd` options can be present; if multiple of these options are listed, the last one listed is accepted and the others are ignored.

The option is one or more of the following:

`m`

print makefile dependencies to stdout.

`md`

print makefile dependencies to `filename.d`, where `filename` is the root name of the input file being processed.

`mm`

print makefile dependencies to stdout, ignoring system include files.

`mmd`

print makefile dependencies to `filename.d`, where `filename` is the root name of the input file being processed, ignoring system include files.

`[no]comment`

(don't) retain comments in output.

`[suffix:]<suff>`

use `<suff>` as the suffix of the output file containing makefile dependencies.

–Mdll

This Windows-only flag has been deprecated. Refer to `-Bdynamic`. This flag was used to link with the DLL versions of the runtime libraries, and it was required when linking with any DLL built by any of The Portland Group compilers. This option implied `-D_DLL`, which defines the preprocessor symbol `_DLL`.

–Mgccbug[s]

match the behavior of certain gcc bugs.

–Miface[=option]

adjusts the calling conventions for Fortran, where `option` is one of the following:

`unix`

(Win32 only) uses UNIX calling conventions, no trailing underscores.

`cref`

uses CREF calling conventions, no trailing underscores.

`mixed_str_len_arg`

places the lengths of character arguments immediately after their corresponding argument. Has affect only with the CREF calling convention.

`nomixed_str_len_arg`

places the lengths of character arguments at the end of the argument list. Has affect only with the CREF calling convention.

`-Minfo[=option [,option, ...]]`

instructs the compiler to produce information on standard error, where option is one of the following:

`all`

instructs the compiler to produce all available `-Minfo` information. Implies a number of suboptions:

`-Mneginfo=accel,inline,ipa,loop,lre,mp,opt,par,vect`

`accel`

instructs the compiler to enable accelerator information.

`ccff`

instructs the compiler to append common compiler feedback format information, such as optimization information, to the object file.

`ftn`

instructs the compiler to enable Fortran-specific information.

`hpf`

instructs the compiler to enable HPF-specific information.

`inline`

instructs the compiler to display information about extracted or inlined functions. This option is not useful without either the `-Mextract` or `-Minline` option.

`intensity`

instructs the compiler to provide informational messages about the intensity of the loop. Specify `<n>` to get messages on nested loops.

- For floating point loops, intensity is defined as the number of floating point operations divided by the number of floating point loads and stores.
- For integer loops, the loop intensity is defined as the total number of integer arithmetic operations, which may include updates of loop counts and addresses, divided by the total number of integer loads and stores.
- By default, the messages just apply to innermost loops.

`ipa`

instructs the compiler to display information about interprocedural optimizations.

`loop`

instructs the compiler to display information about loops, such as information on vectorization.

`lre`

instructs the compiler to enable LRE, loop-carried redundancy elimination, information.

`mp`

instructs the compiler to display information about parallelization.

`opt`

instructs the compiler to display information about optimization.

par

instructs the compiler to enable parallelizer information.

pfo

instructs the compiler to enable profile feedback information.

time

instructs the compiler to display compilation statistics.

unroll

instructs the compiler to display information about loop unrolling.

vect

instructs the compiler to enable vectorizer information.

–Minform=level

instructs the compiler to display error messages at the specified and higher levels, where level is one of the following:

fatal

instructs the compiler to display fatal error messages.

[no]file

instructs the compiler to print or not print source file names as they are compiled. The default is to print the names: `–Minform=file`.

inform

instructs the compiler to display all error messages (inform, warn, severe and fatal).

severe

instructs the compiler to display severe and fatal error messages.

warn

instructs the compiler to display warning, severe and fatal error messages.

To set this option in PVE, use the Fortran | Diagnostics | Warning Level property, described in “Warning Level” on page 404.

–Minstrumentation=option

specifies the level of instrumentation calls generated. This option implies `–Minfo=ccff`, `–Mframe`.

option is one of the following:

level

specifies the level of instrumentation calls generated.

function (default)

generates instrumentation calls for entry and exit to functions.

Just after function entry and just before function exit, the following profiling functions are called with the address of the current function and its call site. (linux86-64 only).

```
void __cyg_profile_func_enter (void *this_fn, void *call_site);  
void __cyg_profile_func_exit (void *this_fn, void *call_site);
```

In these calls, the first argument is the address of the start of the current function.

To set this option in PVE, use the Fortran | Diagnostics | Warning Level property, described in “Warning Level” on page 404.

-Mkeepasm

instructs the compiler to keep the assembly file as compilation continues. Normally, the assembler deletes this file when it is finished. The assembly file has the same filename as the source file, but with a .s extension.

To set this option in PVE, use the Fortran | Output | Assembler Output property, described in “Generate Assembly” on page 404.

-Mlist

instructs the compiler to create a listing file. The listing file is `filename.lst`, where the name of the source file is `filename.f`.

-Mmakedll

generate a dynamic link library (DLL).

-Mmakeimplib

generate an import library for a DLL without creating the DLL. When used without `-def:deffile`, passes the switch `-def` to the librarian without a deffile.

-Mnames=lowercase|uppercase

specifies the case for the names of Fortran externals .

- lowercase - Use lowercase for Fortran externals.
- uppercase - Use uppercase for Fortran externals.

-Mneginfo[=option [,option,...]]

instructs the compiler to produce information on standard error, where option is one of the following:

all

instructs the compiler to produce all available information on why various optimizations are not performed.

accel

instructs the compiler to enable accelerator information.

ccff

instructs the compiler to append information, such as optimization information, to the object file.

concur

instructs the compiler to produce all available information on why loops are not automatically parallelized. In particular, if a loop is not parallelized due to potential data dependence, the variable(s) that cause the potential dependence are listed in the messages that you see when using the option `-Mneginfo`.

ftn

instructs the compiler to enable Fortran-specific information.

hpf

instructs the compiler to enable HPF-specific information.

inline

instructs the compiler to display information about extracted or inlined functions. This option is not useful without either the `-Mextract` or `-Minline` option.

ipa

instructs the compiler to display information about interprocedural optimizations.

loop

instructs the compiler to display information about loops, such as information on vectorization.

lre

instructs the compiler to enable LRE, loop-carried redundancy elimination, information.

mp

instructs the compiler to display information about parallelization.

opt

instructs the compiler to display information about optimization.

par

instructs the compiler to enable parallelizer information.

pfo

instructs the compiler to enable profile feedback information.

vect

instructs the compiler to enable vectorizer information.

–Mnolist

the compiler does not create a listing file. This is the default.

–Mnoopenmp

when used in combination with the `-mp` option, the compiler ignores OpenMP parallelization directives or pragmas, but still processes SGI-style parallelization directives or pragmas.

–Mnosgimp

when used in combination with the `-mp` option, the compiler ignores SGI-style parallelization directives or pragmas, but still processes OpenMP parallelization directives or pragmas.

–Mnopgdllmain

do not link the module containing the default `DllMain()` into the DLL. If you want to replace the default `DllMain()` routine with a custom `DllMain()`, use this flag and add the object containing the custom `DllMain()` to the link line. The latest version of the default `DllMain()` used by PGFORTRAN is included in the Release Notes for each release; the PGFORTRAN-specific code in this routine must be incorporated into the custom version of `DllMain()` to ensure the appropriate function of your DLL.

–Mpreprocess

perform cpp-like preprocessing on assembly and Fortran input source files.

To set this option in PVE, use the Fortran | Preprocessor | Preprocess Source File property, described in “Preprocessor Definitions” on page 381.

–Mwritable_strings

stores string constants in the writable data segment.

Note

Options `-xs` and `-xst` include `-Mwritable_strings`.

Chapter 3. OpenMP Reference Information

The PGF77, PGF95, and PGFORTRAN Fortran compilers support the OpenMP Fortran Application Program Interface.

This chapter contains detailed descriptions of each of the OpenMP Fortran directives that PGI supports. In addition, the section “Directive and Pragma Clauses” in the PGI Compiler User’s Guide contains information about the clauses associated with these directives .

Tasks

Every part of an OpenMP program is part of a task. The Task Overview section of the PGI Compiler User’s Guide provides a general overview of tasks and general terminology associated with tasks. This section provides more detailed information about tasks, including tasks scheduling points and the task construct.

Task Characteristics and Activities

A task, whose execution can be performed immediately or delayed, has these characteristics:

- Code to execute
- A data environment - that is, it owns its data
- An assigned thread that executes the code and uses the data.

There are two activities associated with tasks: packaging and execution.

- Packaging: Each encountering thread packages a new instance of a task - code and data.
- Execution: Some thread in the team executes the task at some later time.

Task Scheduling Points

PGI currently supports four task scheduling points: at the beginning of a task, at the end of a task, a taskwait, and at a barrier.

- Beginning of a task.

At the beginning of a task, the task can be executed immediately or registered for later execution. A programmer-specified "if" clause that is FALSE forces immediate execution of the task. The implementation can also force immediate execution; for example, a task within a task is never registered for later execution, it executes immediately.

- End of a task

At the end of a task, the behavior of the scheduling point depends on how the task was executed. If the task was immediately executed, execution continues to the next statement. If it was previously registered and is being executed "out of sequence", control returns to where the task was executed.

- Taskwait

A taskwait executes all registered tasks at the time it is called. In addition to executing all tasks registered by the calling thread, it also executes tasks previously registered by other threads. Let's take a quick look at this process; suppose the following is true:

- Thread 0 called taskwait and is executing tasks.
- Thread 1 is registering tasks.

Depending on the timing between thread 0 and thread 1, thread 0 may execute none of the tasks, all of the tasks, or some of tasks.

Note

Taskwait waits only for immediate children tasks, not for descendant tasks. You can achieve waiting on descendants but ensuring that each child also waits on its children.

- Barrier

A barrier can be explicit or implicit. An example of an implicit barrier is the end of a parallel region.

The barrier effectively contains taskwaits. All threads must arrive at the barrier for the barrier to complete. This rule guarantees that all tasks have been executed at the completion of the barrier.

Task Construct

A task construct is a task directive plus a structured block, with the following syntax:

```
#pragma omp task [clause[[,]clause] ...]
    structured-block
```

where clause can be one of the following:

```
if (expression)
untied
shared (list)
private (list)
firstprivate (list)
default( shared | none )
```

Consider the following simple example of a program using tasks. This example illustrates the difference between registering tasks and executing tasks, a concept that is fundamental to understanding tasks.

This program contains a parallel region that contains a single region. The single region contains a loop that registers 10 tasks. Before reading the explanation that follows the example, consider what happens if you use four threads with this example.

Example 3.1. OpenMP Task Fortran Example

```

PROGRAM MAIN
  INTEGER I
  INTEGER omp_get_thread_num
!$OMP PARALLEL PRIVATE(I)
!$OMP SINGLE
  DO I = 1, 10
    CALL SLEEP(MOD(I,2))
    PRINT *, "TASK ", I, " REGISTERED BY THREAD ", omp_get_thread_num()
!$OMP TASK FIRSTPRIVATE(I)
    CALL SLEEP(MOD(I,5))
    PRINT *, "TASK ", I, " EXECUTED BY THREAD ", omp_get_thread_num()
!$OMP END TASK
  ENDDO
!$OMP END SINGLE
!$OMP END PARALLEL
END

```

If you run this program with four threads, 0 through 3, one thread is in the single region registering tasks. The other three threads are in the implied barrier at the end of the single region executing tasks. Further, when the thread executing the single region completes registering the tasks, it joins the other threads and executes tasks.

The program includes calls to `sleep` to slow the program and allow all threads to participate.

The output for the Fortran example is similar to the following. In this output, thread 1 was registering tasks while the other three threads - 0, 2, and 3 - were executing tasks. When all 10 tasks were registered, thread 1 began executing tasks as well.

```

TASK 1  REGISTERED BY THREAD 1
TASK 2  REGISTERED BY THREAD 1
TASK 1  EXECUTED BY THREAD 0
TASK 3  REGISTERED BY THREAD 1
TASK 4  REGISTERED BY THREAD 1
TASK 2  EXECUTED BY THREAD 3
TASK 5  REGISTERED BY THREAD 1
TASK 6  REGISTERED BY THREAD 1
TASK 6  EXECUTED BY THREAD 3
TASK 5  EXECUTED BY THREAD 3
TASK 7  REGISTERED BY THREAD 1
TASK 8  REGISTERED BY THREAD 1
TASK 3  EXECUTED BY THREAD 0
TASK 9  REGISTERED BY THREAD 1
TASK 10 REGISTERED BY THREAD 1
TASK 10 EXECUTED BY THREAD 1
TASK 4  EXECUTED BY THREAD 2
TASK 7  EXECUTED BY THREAD 0
TASK 8  EXECUTED BY THREAD 3
TASK 9  EXECUTED BY THREAD 1

```

Parallelization Directives

Parallelization directives, as described in “Using OpenMP” in the PGI Compiler User’s Guide, are comments in a program that are interpreted by the PGI Fortran compilers when the option `-mp` is specified on the command line. The form of a parallelization directive is:

```
sentinel directive_name [clauses]
```

The examples given with each section use the routines `omp_get_num_threads()` and `omp_get_thread_num()`. They return the number of threads currently in the team executing the parallel region and the thread number within the team, respectively. For more information, refer to “run-time Library Routines” in the PGI Compiler User’s Guide.

Note

Directives which are presented in pairs must be used in pairs.

This section describes the details of these directives that were summarized in “Using OpenMP” in the PGI Compiler User’s Guide. For each directive, this section describes the overall purpose, the syntax, the clauses associated with it, the usage, and examples of how to use it.

ATOMIC

The OpenMP ATOMIC directive is semantically equivalent to a single statement in a CRITICAL...END CRITICAL directive.

Syntax:

```
!$OMP ATOMIC
```

Usage:

The ATOMIC directive is semantically equivalent to enclosing the following single statement in a CRITICAL / END CRITICAL directive pair.

The statements must be one of the following forms:

```
x = x operator expr
```

```
x = intrinsic (x, expr)
```

```
x = expr operator x
```

```
x = intrinsic (expr, x)
```

where `x` is a scalar variable of intrinsic type, `expr` is a scalar expression that does not reference `x`, `intrinsic` is one of MAX, MIN, IAND, IOR, or IEOR, and `operator` is one of +, *, -, /, .AND., .OR., .EQV., or .NEQV..

BARRIER

The OpenMP BARRIER directive defines a point in a program where each thread waits for all other threads to arrive before continuing with program execution.

Syntax:

```
!$OMP BARRIER
```

Usage:

There may be occasions in a parallel region when it is necessary that all threads complete work to that point before any thread is allowed to continue. The BARRIER directive synchronizes all threads at such a point in a program. Multiple barrier points are allowed within a parallel region. The BARRIER directive must either be executed by all threads executing the parallel region or by none of them.

CRITICAL ... END CRITICAL

The CRITICAL...END CRITICAL directive requires a thread to wait until no other thread is executing within a critical section.

Syntax:

```
!$OMP CRITICAL [(name)]  
< Fortran code executed in body of critical section >  
!$OMP END CRITICAL [(name)]
```

Usage:

Within a parallel region, there may exist subregions of code that will not execute properly when executed by multiple threads simultaneously. This issue is often due to a shared variable that is written and then read again.

The CRITICAL... END CRITICAL directive pair defines a subsection of code within a parallel region, referred to as a critical section, which is executed one thread at a time.

The first thread to arrive at a critical section is the first to execute the code within the section. The second thread to arrive does not begin execution of statements in the critical section until the first thread exits the critical section. Likewise, each of the remaining threads waits to execute the statements in the critical section until the previous thread exits the critical section.

You can use the optional *name argument* to identify the critical region. Names that identify critical regions have external linkage and are in a name space separate from the name spaces used by labels, tags, members, and ordinary identifiers. If a name argument appears on a CRITICAL directive, the same name must appear on the END CRITICAL directive.

Note

Critical sections cannot be nested, and any such specifications are ignored. Branching into or out of a critical section is illegal.

Fortran Example of Critical...End Critical directive:

```

PROGRAM CRITICAL_USE
REAL A(100,100),MX, LMX
INTEGER I, J
MX = -1.0
LMX = -1.0
CALL RANDOM_SEED()
CALL RANDOM_NUMBER(A)
!$OMP PARALLEL PRIVATE(I), FIRSTPRIVATE(LMX)
!$OMP DO
  DO J=1,100
    DO I=1,100
      LMX = MAX(A(I,J),LMX)
    ENDDO
  ENDDO
!$OMP CRITICAL
  MX = MAX(MX,LMX)
!$OMP END CRITICAL
!$OMP END PARALLEL
  PRINT *, "MAX VALUE OF A IS ", MX
END

```

This program could also be implemented without the critical region by declaring `MX` as a reduction variable and performing the `MAX` calculation in the loop using `MX` directly rather than using `LMX`. Refer to [“PARALLEL ... END PARALLEL”](#) and [“DO...END DO”](#) for more information on how to use the `REDUCTION` clause on a parallel DO loop.

C\$DOACROSS

The `C$DOACROSS` directive, while not part of the OpenMP standard, is supported for compatibility with programs parallelized using legacy SGI-style directives.

Syntax:

```

C$DOACROSS [ Clauses ]
< Fortran DO loop to be executed in parallel >

```

Clauses:

<code>{PRIVATE LOCAL} (list)</code>	<code>CHUNK=<integer_expression></code>
<code>{SHARED SHARE} (list)</code>	<code>IF (logical_expression)</code>
<code>MP_SCHEDTYPE={SIMPLE INTERLEAVE}</code>	

Usage:

The `C$DOACROSS` directive has the effect of a combined parallel region and parallel DO loop applied to the loop immediately following the directive. It is very similar to the OpenMP `PARALLEL DO` directive, but provides for backward compatibility with codes parallelized for SGI systems prior to the OpenMP standardization effort.

The `C$DOACROSS` directive must not appear within a parallel region. It is a shorthand notation that tells the compiler to parallelize the loop to which it applies, even though that loop is not contained within a parallel

region. While this syntax is more convenient, it should be noted that if multiple successive DO loops are to be parallelized it is more efficient to define a single enclosing parallel region and parallelize each loop using the OpenMP DO directive.

A variable declared PRIVATE or LOCAL to a C\$DOACROSS loop is treated the same as a private variable in a parallel region or DO. A variable declared SHARED or SHARE to a C\$DOACROSS loop is shared among the threads, meaning that only 1 copy of the variable exists to be used and/or modified by all of the threads. This is equivalent to the default status of a variable that is not listed as PRIVATE in a parallel region or DO. This same default status is used in C\$DOACROSS loops as well. For more information on clauses, refer to [“Directive Clauses,” on page 98](#).

DO...END DO

The OpenMP DO...END DO directive supports parallel execution and the distribution of loop iterations across available threads in a parallel region.

Syntax:

```
!$OMP DO [Clauses]
< Fortran DO loop to be executed in parallel >
!$OMP END DO [NOWAIT]
```

Clauses:

PRIVATE(list)	SCHEDULE (type [, chunk])
FIRSTPRIVATE(list)	COLLAPSE (n)
LASTPRIVATE(list)	ORDERED
REDUCTION({operator intrinsic} : list)	

Usage:

The real purpose of supporting parallel execution is the distribution of work across the available threads. The DO... END DO directive pair provides a convenient mechanism for the distribution of loop iterations across the available threads in a parallel region.

While you can explicitly manage work distribution with constructs such as the following one, these constructs are not in the form of directives.

Examples:

```
IF (omp_get_thread_num() .EQ. 0)
THEN
...
ELSE IF (omp_get_thread_num() .EQ. 1)
THEN
...
ENDIF
```

Tips

Remember these items about clauses in the DO...END DO directives:

- Variables declared in a **PRIVATE** list are treated as private to each thread participating in parallel execution of the loop, meaning that a separate copy of the variable exists with each thread.
- Variables declared in a **FIRSTPRIVATE** list are **PRIVATE**, and are initialized from the original object existing before the construct.
- Variables declared in a **LASTPRIVATE** list are **PRIVATE**, and the thread that executes the sequentially last iteration updates the version of the object that existed before the construct.
- The **REDUCTION** clause for the directive is described in [“REDUCTION,” on page 101](#).
- The **SCHEDULE** clause specifies how iterations of the DO loop are divided up between threads. For more information on this clause, refer to [“SCHEDULE,” on page 102](#).
- If **ORDERED** code blocks are contained in the dynamic extent of the DO directive, the **ORDERED** clause must be present. For more information on **ORDERED** code blocks, refer to [“ORDERED”](#).
- The **DO... END DO** directive pair directs the compiler to distribute the iterative DO loop immediately following the **!\$OMP DO** directive across the threads available to the program. The DO loop is executed in parallel by the team that was started by an enclosing parallel region. If the **!\$OMP END DO** directive is not specified, the **!\$OMP DO** is assumed to end with the enclosed DO loop. **DO... END DO** directive pairs may not be nested. Branching into or out of a **!\$OMP DO** loop is not supported.
- By default, there is an implicit barrier after the end of the parallel loop; the first thread to complete its portion of the work waits until the other threads have finished their portion of work. If **NOWAIT** is specified, the threads will not synchronize at the end of the parallel loop.

In addition to the preceding items, remember these items about **!\$OMP DO** loops :

- The DO loop index variable is always private.
- **!\$OMP DO** loops must be executed by all threads participating in the parallel region or none at all.
- The **END DO** directive is optional, but if it is present it must appear immediately after the end of the enclosed DO loop.
- Values of the loop control expressions and the chunk expressions must be the same for all threads executing the loop.

Example:

```
PROGRAM DO_USE
  REAL A(1000), B(1000)
  DO I=1,1000
    B(I) = FLOAT(I)
  ENDDO
!$OMP PARALLEL
!$OMP DO
  DO I=1,1000
    A(I) = SQRT(B(I));
  ENDDO
  ...
!$OMP END PARALLEL
  ...
END
```

FLUSH

The OpenMP FLUSH directive ensures that processor-visible data items are written back to memory at the point at which the directive appears.

Syntax:

```
!$OMP FLUSH [(list)]
```

Usage:

The OpenMP FLUSH directive ensures that all processor-visible data items, or only those specified in `list`, when it is present, are written back to memory at the point at which the directive appears.

MASTER ... END MASTER

The MASTER...END MASTER directive allows the user to designate code that must execute on a master thread and that is skipped by other threads in the team of threads.

Syntax:

```
!$OMP MASTER
< Fortran code executed in body of MASTER section >
!$OMP END MASTER
```

Usage:

A master thread is a single thread of control that begins an OpenMP program and which is present for the duration of the program. In a parallel region of code, there may be a sub-region of code that should execute only on the master thread. Instead of ending the parallel region before this subregion and then starting it up again after this subregion, the MASTER... END MASTER directive pair allows the user to conveniently designate code that executes on the master thread and is skipped by the other threads.

- There is no implied barrier on entry to or exit from a master section of code.
- Nested master sections are ignored.
- Branching into or out of a master section is not supported.

Examples:

Example of Fortran **MASTER...END MASTER** directive

```
PROGRAM MASTER_USE
  INTEGER A(0:1)
  INTEGER omp_get_thread_num
  A=-1
!$OMP PARALLEL
  A(omp_get_thread_num()) = omp_get_thread_num()
!$OMP MASTER
  PRINT *, "YOU SHOULD ONLY SEE THIS ONCE"
!$OMP END MASTER
!$OMP END PARALLEL
  PRINT *, "A(0)=", A(0), " A(1)=", A(1)
END
```

ORDERED

The OpenMP **ORDERED** directive allows the user to identify a portion of code within an ordered code block that must be executed in the original, sequential order, while allowing parallel execution of statements outside the code block.

Syntax:

```
!$OMP ORDERED
< Fortran code block executed by processor >
!$OMP END ORDERED
```

Usage:

The **ORDERED** directive can appear only in the dynamic extent of a **DO** or **PARALLEL DO** directive that includes the **ORDERED** clause. The structured code block between the **ORDERED** / **END ORDERED** directives is executed by only one thread at a time, and in the order of the loop iterations. This sequentializes the ordered code block while allowing parallel execution of statements outside the code block. The following additional restrictions apply to the **ORDERED** directive:

- The ordered code block must be a structured block.
- It is illegal to branch into or out of the block.
- A given iteration of a loop with a **DO** directive cannot execute the same **ORDERED** directive more than once, and cannot execute more than one **ORDERED** directive.

PARALLEL ... END PARALLEL

The OpenMP **PARALLEL...END PARALLEL** directive supports a fork/join execution model in which a single thread executes all statements until a parallel region is encountered.

Syntax:

```
!$OMP PARALLEL [Clauses]
< Fortran code executed in body of parallel region >
!$OMP END PARALLEL
```

Clauses:

PRIVATE (list)	REDUCTION ([{operator intrinsic}:] list)
SHARED (list)	COPYIN (list)
DEFAULT (PRIVATE SHARED NONE)	IF (scalar_logical_expression)
FIRSTPRIVATE (list)	NUM_THREADS (scalar_integer_expression)

Usage:

This directive pair declares a region of parallel execution. It directs the compiler to create an executable in which the statements within the structured block, such as between **PARALLEL** and **PARALLEL END** for directives, are executed by multiple lightweight threads. The code that lies within this structured block is called a *parallel region*.

The OpenMP parallelization directives support a fork/join execution model in which a single thread executes all statements until a parallel region is encountered. At the entrance to the parallel region, a system-dependent number of symmetric parallel threads begin executing all statements in the parallel region redundantly. These threads share work by means of work-sharing constructs such as parallel DO loops or FOR loops.

- The number of threads in the team is controlled by the `OMP_NUM_THREADS` environment variable. If `OMP_NUM_THREADS` is not defined, the program executes parallel regions using only one processor.
- Branching into or out of a parallel region is not supported.
- All other shared-memory parallelization directives must occur within the scope of a parallel region. Nested `PARALLEL... END PARALLEL` directive pairs are not supported and are ignored.
- There is an implicit barrier at the end of the parallel region, which, in the directive, is denoted by the `END PARALLEL` directive. When all threads have completed execution of the parallel region, a single thread resumes execution of the statements that follow.

Note

By default, there is no work distribution in a parallel region. Each active thread executes the entire region redundantly until it encounters a directive that specifies work distribution. For work distribution, see the `DO`, `PARALLEL DO`, or `DOACROSS` directives.

Example:

```
PROGRAM WHICH_PROCESSOR_AM_I
  INTEGER A(0:1)
  INTEGER omp_get_thread_num
  A(0) = -1
  A(1) = -1
!$OMP PARALLEL
  A(omp_get_thread_num()) = omp_get_thread_num()
!$OMP END PARALLEL
  PRINT *, "A(0)=", A(0), " A(1)=", A(1)
END
```

Clause Usage:

COPYIN: The `COPYIN` clause applies only to `THREADPRIVATE` common blocks. In the presence of the `COPYIN` clause, data from the master thread's copy of the common block is copied to the `THREADPRIVATE` copies upon entry to the parallel region.

IF: In the presence of an `IF` clause, the parallel region is executed in parallel only if the corresponding `scalar_logical_expression` evaluates to `.TRUE.`. Otherwise, the code within the region is executed by a single processor, regardless of the value of the environment variable `OMP_NUM_THREADS`.

NUM_THREADS: If the `NUM_THREADS` clause is present, the corresponding `scalar_integer_expression` must evaluate to a positive integer value. This value sets the maximum number of threads used during execution of the parallel region. A `NUM_THREADS` clause overrides either a previous call to the library routine `omp_set_num_threads()` or the setting of the `OMP_NUM_THREADS` environment variable.

PARALLEL DO

The OpenMP PARALLEL DO directive is a shortcut for a PARALLEL region that contains a single DO directive.

Note

The OpenMP PARALLEL DO or DO directive must be immediately followed by a DO statement (as defined by R818 of the ANSI Fortran standard). If you place another statement or an OpenMP directive between the PARALLEL DO or DO directive and the DO statement, the compiler issues a syntax error.

Syntax:

```
!$OMP PARALLEL DO [CLAUSES]
< Fortran DO loop to be executed in parallel >
!$OMP END PARALLEL DO
```

Clauses:

PRIVATE(list)	COPYIN(list)
SHARED(list)	IF(scalar_logical_expression)
DEFAULT(PRIVATE SHARED NONE)	NUM_THREADS(scalar_integer_expression)
FIRSTPRIVATE(list)	SCHEDULE (type [, chunk])
LASTPRIVATE(list)	COLLAPSE (n)
REDUCTION([{operator intrinsic} :] list)	ORDERED

Usage:

The semantics of the PARALLEL DO directive are identical to those of a parallel region containing only a single parallel DO loop and directive. The available clauses are the same as those defined in “[PARALLEL ... END PARALLEL](#),” on page 88 and “[DO...END DO](#)”.

Note

The END PARALLEL DO directive is optional.

PARALLEL SECTIONS

The OpenMP `PARALLEL SECTIONS / END SECTIONS` directive pair define tasks to be executed in parallel; that is, they define a non-iterative work-sharing construct without the need to define an enclosing parallel region.

Syntax:

```
!$OMP PARALLEL SECTIONS [CLAUSES]
[!$OMP SECTION]
< Fortran code block executed by processor i >
[!$OMP SECTION]
< Fortran code block executed by processor j >
...
!$OMP END SECTIONS [NOWAIT]
```

Clauses:

<code>PRIVATE(list)</code>	<code>REDUCTION({operator intrinsic} : list)</code>
<code>SHARED(list)</code>	<code>COPYIN (list)</code>
<code>DEFAULT(PRIVATE SHARED NONE)</code>	<code>IF(scalar_logical_expression)</code>
<code>FIRSTPRIVATE(list)</code>	<code>NUM_THREADS(scalar_integer_expression)</code>
<code>LASTPRIVATE(list)</code>	

Usage:

The `PARALLEL SECTIONS / END SECTIONS` directive pair define a non-iterative work-sharing construct without the need to define an enclosing parallel region. Each section is executed by a single processor. If there are more processors than sections, some processors will have no work and will jump to the implied barrier at the end of the construct. If there are more sections than processors, one or more processors will execute more than one section.

A `SECTION` directive may only appear within the lexical extent of the enclosing `PARALLEL SECTIONS / END SECTIONS` directives. In addition, the code within the `PARALLEL SECTIONS / END SECTIONS` directives must be a structured block, and the code in each `SECTION` must be a structured block.

Semantics are identical to a parallel region containing only an `omp sections` pragma and the associated structured block. The available clauses are as defined in “[PARALLEL ... END PARALLEL](#),” on page 88 and “[DO...END DO](#)”.

PARALLEL WORKSHARE ... END PARALLEL WORKSHARE

The OpenMP `PARALLEL WORKSHARE` Fortran directive provides a short form method of including a `WORKSHARE` directive inside a `PARALLEL` construct. The `END PARALLEL WORKSHARE` directive is optional.

Syntax:

```
!$OMP PARALLEL WORKSHARE [CLAUSES]
  < Fortran structured block to be executed in parallel >
[!$OMP END PARALLEL WORKSHARE]
```

```
!$OMP PARALLEL DO [CLAUSES]
  < Fortran DO loop to be executed in parallel >
[!$OMP END PARALLEL DO]
```

Clauses:

<code>PRIVATE(list)</code>	<code>COPYIN (list)</code>
<code>SHARED(list)</code>	<code>IF(scalar_logical_expression)</code>
<code>DEFAULT(PRIVATE SHARED NONE)</code>	<code>NUM_THREADS(scalar_integer_expression)</code>
<code>FIRSTPRIVATE(list)</code>	<code>SCHEDULE (type [, chunk])</code>
<code>LASTPRIVATE(list)</code>	<code>COLLAPSE (n)</code>
<code>REDUCTION({operator intrinsic} : list)</code>	<code>ORDERED</code>

Usage:

The OpenMP `PARALLEL WORKSHARE` directive provides a short form method of including a `WORKSHARE` directive inside a `PARALLEL` construct. The semantics of the `PARALLEL WORKSHARE` directive are identical to those of a parallel region containing a single `WORKSHARE` construct.

The `END PARALLEL WORKSHARE` directive is optional, and `NOWAIT` may not be specified on an `END PARALLEL WORKSHARE` directive. The available clauses are as defined in [“PARALLEL ... END PARALLEL ,” on page 88](#).

SECTIONS ... END SECTIONS

The OpenMP SECTIONS / END SECTIONS directive pair define a non-iterative work-sharing construct within a parallel region in which each section is executed by a single processor.

Syntax:

```
!$OMP SECTIONS [ Clauses ]
[!$OMP SECTION]
    < Fortran code block executed by processor i >
[!$OMP SECTION]
    < Fortran code block executed by processor j >
    ...
!$OMP END SECTIONS [NOWAIT]
```

Clauses:

PRIVATE(list)

FIRSTPRIVATE(list)

LASTPRIVATE(list)

REDUCTION({operator | intrinsic} : list)

Usage:

The SECTIONS / END SECTIONS directive pair define a non-iterative work-sharing construct within a parallel region. Each section is executed by a single processor. If there are more processors than sections, some processors have no work and thus jump to the implied barrier at the end of the construct. If there are more sections than processors, one or more processors must execute more than one section.

A SECTION directive may only appear within the lexical extent of the enclosing SECTIONS / END SECTIONS directives. In addition, the code within the SECTIONS / END SECTIONS directives must be a structured block.

The available clauses are as defined in [“PARALLEL ... END PARALLEL,”](#) on page 88 and [“DO...END DO”](#).

SINGLE ... END SINGLE

The SINGLE...END SINGLE directive designates code that executes on a single thread and that is skipped by the other threads.

Syntax:

```
!$OMP SINGLE [Clauses]
< Fortran code executed in body of SINGLE processor section >
!$OMP END SINGLE [NOWAIT]
```

Clauses:

PRIVATE(list)

FIRSTPRIVATE(list)

COPYPRIVATE(list)

Usage:

In a parallel region of code, there may be a sub-region of code that only executes correctly on a single thread. Instead of ending the parallel region before this subregion and then starting it up again after this subregion, the SINGLE...END SINGLE directive pair lets you conveniently designate code that executes on a single thread and is skipped by the other threads. There is an implied barrier on exit from a SINGLE...END SINGLE section of code unless the optional NOWAIT clause is specified.

Nested single process sections are ignored. Branching into or out of a single process section is not supported.

Examples:

```
PROGRAM SINGLE_USE
  INTEGER A(0:1)
  INTEGER omp_get_thread_num()
!$OMP PARALLEL
  A(omp_get_thread_num()) = omp_get_thread_num()
!$OMP SINGLE
  PRINT *, "YOU SHOULD ONLY SEE THIS ONCE"
!$OMP END SINGLE
!$OMP END PARALLEL
  PRINT *, "A(0)=", A(0), " A(1)=", A(1)
END
```

TASK

The OpenMP TASK directive defines an explicit task.

Syntax:

```
!$OMP TASK [Clauses]
< Fortran code executed as task >
!$OMP END TASK
```

Clauses:

IF(scalar_logical_expression)	PRIVATE(list)
UNTIED	FIRSTPRIVATE(list)
DEFAULT(private firstprivate shared none)	SHARED(list)

Usage:

The TASK / END TASK directive pair defines an explicit task.

When a thread encounters a task construct, a task is generated from the code for the associated structured block. The data environment of the task is created according to the data-sharing attribute clauses on the task construct and any defaults that apply. The encountering thread may immediately execute the task, or delay its execution. If the task execution is delayed, then any thread in the team may be assigned the task. Completion of the task can be guaranteed using task synchronization constructs.

A task construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

When an if clause is present on a task construct and the if clause expression evaluates to false, the encountering thread must suspend the current task region and begin execution of the generated task immediately, and the suspended task region may not be resumed until the generated task is completed. The task still behaves as a distinct task region with respect to data environment, lock ownership, and synchronization constructs.

Note

Use of a variable in an if clause expression of a task construct causes an implicit reference to the variable in all enclosing constructs.

A thread that encounters a task scheduling point within the task region may temporarily suspend the task region. By default, a task is tied and its suspended task region can only be resumed by the thread that started its execution. If the untied clause is present on a task construct, any thread in the team can resume the task region after a suspension.

The task construct includes a task scheduling point in the task region of its generating task, immediately following the generation of the explicit task. Each explicit task region includes a task scheduling point at its point of completion. An implementation may add task scheduling points anywhere in untied task regions.

Note

When storage is shared by an explicit task region, it is the programmer's responsibility to ensure, by adding proper synchronization, that the storage does not reach the end of its lifetime before the explicit task region completes its execution.

Restrictions:

The following restrictions apply to the TASK directive:

- A program that branches into or out of a task region is non-conforming.
- A program must not depend on any ordering of the evaluations of the clauses of the task directive, or on any side effects of the evaluations of the clauses.
- At most one *if* clause can appear on the directive.
- Unsynchronized use of Fortran I/O statements by multiple tasks on the same unit has unspecified behavior.

TASKWAIT

The OpenMP TASKWAIT directive specifies a wait on the completion of child tasks generated since the beginning of the current task.

Syntax:

```
!$OMP TASKWAIT
```

Clauses:

IF(scalar_logical_expression)	PRIVATE(list)
UNTIED	FIRSTPRIVATE(list)
DEFAULT(private firstprivate shared none)	SHARED(list)

Usage:

The OpenMP TASKWAIT directive specifies a wait on the completion of child tasks generated since the beginning of the current task.

Restrictions:

The following restrictions apply to the TASKWAIT directive:

- The TASKWAIT directive may be placed only at a point where a base language statement is allowed.
- The taskwait directive may not be used in place of the statement following an *if*, *while*, *do*, *switch*, or *label*.

THREADPRIVATE

The OpenMP `THREADPRIVATE` directive identifies a Fortran common block as being private to each thread.

Syntax:

```
!$OMP THREADPRIVATE (list)
```

Usage:

The `list` is a comma-separated list of named variables to be made private to each thread or named common blocks to be made private to each thread but global within the thread. Common block names must appear between slashes, such as `/common_block_name/`.

This directive must appear in the declarations section of a program unit after the declaration of any common blocks or variables listed. On entry to a parallel region, data in a `THREADPRIVATE` common block or variable is undefined unless `COPYIN` is specified on the `PARALLEL` directive. When a common block or variable that is initialized using `DATA` statements appears in a `THREADPRIVATE` directive, each thread's copy is initialized once prior to its first use.

Restrictions:

The following restrictions apply to the `THREADPRIVATE` directive:

- The `THREADPRIVATE` directive must appear after every declaration of a thread private common block.
- Only named common blocks can be made thread private.
- It is illegal for a `THREADPRIVATE` common block or its constituent variables to appear in any clause other than a `COPYIN` clause.
- A variable can appear in a `THREADPRIVATE` directive only in the scope in which it is declared. It must not be an element of a common block or be declared in an `EQUIVALENCE` statement.
- A variable that appears in a `THREADPRIVATE` directive and is not declared in the scope of a module must have the `SAVE` attribute.

WORKSHARE ... END WORKSHARE

The OpenMP WORKSHARE ... END WORKSHARE Fortran directive pair provides a mechanism to effect parallel execution of non-iterative but implicitly data parallel constructs.

Syntax:

```
!$OMP WORKSHARE
  < Fortran structured block to be executed in parallel >
!$OMP END WORKSHARE [NOWAIT]
```

Usage:

The Fortran structured block enclosed by the WORKSHARE ... END WORKSHARE directive pair can consist only of the following types of statements and constructs:

- Array assignments
- Scalar assignments
- FORALL statements or constructs
- WHERE statements or constructs
- OpenMP ATOMIC, CRITICAL or PARALLEL constructs

The work implied by these statements and constructs is split up between the threads executing the WORKSHARE construct in a way that is guaranteed to maintain standard Fortran semantics. The goal of the WORKSHARE construct is to effect parallel execution of non-iterative but implicitly data parallel array assignments, FORALL, and WHERE statements and constructs intrinsic to the Fortran language beginning with Fortran 90. The Fortran structured block contained within a WORKSHARE construct must not contain any user-defined function calls unless the function is ELEMENTAL.

Directive Clauses

Some directives accept clauses that further allow a user to control the scope attributes of variables for the duration of the directive or pragma. Not all clauses are allowed on all directives, so the clauses that are valid are included with the description of the directive. Typically, if no data scope clause is specified for variables, the default scope is *shared*.

The PGI Compiler User's Guide provides a table that contains a brief summary of the clauses associated with OpenMP directives that PGI supports. This section contains more information about each of these clauses. For complete information and more details related to use of these clauses, refer to the OpenMP documentation available on the WorldWide Web.

COLLAPSE (n)

The COLLAPSE(n) clause specifies how many loops are associated with the loop construct.

The parameter of the collapse clause must be a constant positive integer expression. If no COLLAPSE clause is present, the only loop that is associated with the loop construct is the one that immediately follows the construct.

If more than one loop is associated with the loop construct, then the iterations of all associated loops are collapsed into one larger iteration space, which is then divided according to the schedule clause. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

If the loop directive contains a COLLAPSE clause then there may be more than one associated loop.

COPYIN (list)

The COPYIN(list) clause allows threads to access the master thread's value, for a threadprivate variable. You assign the same value to threadprivate variables for each thread in the team executing the parallel region; that is, for each variable specified, the value of the variable in the master thread of the team is copied to the threadprivate copies at the beginning of the parallel region.

The COPYIN clause applies only to THREADPRIVATE common blocks. If you specify a COPYIN clause, here are a few tips:

- You cannot specify the same entity name more than once in the list.
- You cannot specify the same entity name in separate COPYIN clauses of the same directive.
- You cannot specify both a common block name and any variable within that same named common block in the list.
- You cannot specify both a common block name and any variable within that same named common block in separate COPYIN clauses of the same directive.

COPYPRIVATE(list)

The COPYPRIVATE(list) clause specifies that one or more variables should be shared among all threads. This clause provides a mechanism to use a private variable to broadcast a value from one member of a team to the other members.

You use a COPYPRIVATE(list) clause on an END SINGLE directive to cause the variables in the list to be copied from the private copies in the single thread that executes the SINGLE region to the other copies in all other threads of the team at the end of the SINGLE region.

Note

The COPYPRIVATE clause must not appear on the same END SINGLE directive as a NOWAIT clause.

The compiler evaluates a COPYPRIVATE clause before any threads have passed the implied BARRIER directive at the end of that construct.

DEFAULT

The **DEFAULT** clause specifies the behavior of unscoped variables in a parallel region, such as the data-sharing attributes of variables. The **DEFAULT** clause lets you specify the default attribute for variables in the lexical extent of the parallel region. Individual clauses specifying **PRIVATE**, **SHARED**, and so on, override the declared **DEFAULT**.

Specifying **DEFAULT(NONE)** declares that there is no implicit default. With this declaration, each variable in the parallel region must be explicitly listed with an attribute of **PRIVATE**, **SHARED**, **FIRSTPRIVATE**, **LASTPRIVATE**, or **REDUCTION**.

FIRSTPRIVATE(list)

The **FIRSTPRIVATE(list)** clause specifies that each thread should have its own instance of a variable, and that each variable in the list should be initialized with the value of the original variable, because it exists before the parallel construct.

Variables that appear in the list of a **FIRSTPRIVATE** clause are subject to the same semantics as **PRIVATE** variables; however, these variables are initialized from the original object that exists prior to entering the parallel region.

If a directive construct contains a **FIRSTPRIVATE** argument to a Message Passing Interface (MPI) routine performing non-blocking communication, the MPI communication must complete before the end of the construct.

IF()

The **IF()** clause specifies whether a loop should be executed in parallel or in serial.

In the presence of an **IF** clause, the parallel region is executed in parallel only if the corresponding `scalar_logical_expression` evaluates to `.TRUE.`. Otherwise, the code within the region is executed by a single processor, regardless of the value of the environment variable `OMP_NUM_THREADS`.

LASTPRIVATE(list)

The **LASTPRIVATE(list)** clause specifies that the enclosing context's version of the variable is set equal to the *private* version of whichever thread executes the final iteration (for-loop construct).

NOWAIT

The **NOWAIT** clause overrides the barrier implicit in a directive. When you specify **NOWAIT**, it removes the implicit barrier synchronization at the end of a for or sections construct.

NUM_THREADS

The **NUM_THREADS** clause sets the number of threads in a thread team. The `num_threads` clause allows a user to request a specific number of threads for a parallel construct. If the `num_threads` clause is present, then

ORDERED

The **ORDERED** clause specifies that a loop is executed in the order of the loop iterations. This clause is required on a parallel **FOR** statement when an ordered directive is used in the loop.

You use this clause in conjunction with a **DO** or **SECTIONS** construct to impose a serial order on the execution of a section of code. If **ORDERED** constructs are contained in the dynamic extent of the **DO** construct, the ordered clause must be present on the **DO** directive.

PRIVATE

The **PRIVATE** clause specifies that each thread should have its own instance of a variable. Therefore, variables specified in a **PRIVATE** list are private to each thread in a team. In effect, the compiler creates a separate copy of each of these variables for each thread in the team. When an assignment to a private variable occurs, each thread assigns to its local copy of the variable. When operations involving a private variable occur, each thread performs the operations using its local copy of the variable.

Tips about private variables:

- Variables declared private in a parallel region are undefined upon entry to the parallel region. If the first use of a private variable within the parallel region is in a right-hand-side expression, the results of the expression are undefined, indicating the probability of a coding error.
- Variables declared private in a parallel region are undefined when serial execution resumes at the end of the parallel region.

REDUCTION

The **REDUCTION** clause specifies that one or more variables that are private to each thread are the subject of a reduction operation at the end of the parallel region. It updates named variables declared on the clause within the directive construct.

- Intermediate values of **REDUCTION** variables are not used within the parallel construct, other than in the updates themselves.
- Variables that appear in the list of a **REDUCTION** clause must be **SHARED**.
- A private copy of each variable in `list` is created for each thread as if the **PRIVATE** clause had been specified.

Each private copy is initialized according to the operator as specified in the following table:

Table 3.1. Initialization of REDUCTION Variables

Operator / Intrinsic	Initialization		Operator / Intrinsic	Initialization
+	0		.NEQV.	.FALSE.
*	1		MAX	Smallest representable number
-	0		MIN	Largest representable number
.AND.	.TRUE.		IAND	All bits on
.OR.	.FALSE.		IOR	0
.EQV.	.TRUE.		IEOR	0

At the end of the parallel region, a reduction is performed on the instances of variables appearing in `list` using operator or intrinsic as specified in the REDUCTION clause. The initial value of each REDUCTION variable is included in the reduction operation. If the `{operator | intrinsic}` portion of the REDUCTION clause is omitted, the default reduction operator is "+" (addition).

SCHEDULE

The SCHEDULE clause specifies how iterations of the DO loop are divided up between processors. Given a SCHEDULE (type [, chunk]) clause, the type can be STATIC, DYNAMIC, GUIDED, or RUNTIME, defined in the following list.

- When SCHEDULE (STATIC, chunk) is specified, iterations are allocated in contiguous blocks of size chunk. The blocks of iterations are statically assigned to threads in a round-robin fashion in order of the thread ID numbers. The chunk must be a scalar integer expression. If chunk is not specified, a default chunk size is chosen equal to:

```
(number_of_iterations + omp_num_threads() - 1) / omp_num_threads()
```

- When SCHEDULE (DYNAMIC, chunk) is specified, iterations are allocated in contiguous blocks of size chunk. As each thread finishes a piece of the iteration space, it dynamically obtains the next set of iterations. The chunk must be a scalar integer expression. If no chunk is specified, a default chunk size is chosen equal to 1.
- When SCHEDULE (GUIDED, chunk) is specified, the chunk size is reduced in an exponentially decreasing manner with each dispatched piece of the iteration space. Chunk specifies the minimum number of iterations to dispatch each time, except when there are less than chunk iterations remaining to be processed, at which point all remaining iterations are assigned. If no chunk is specified, a default chunk size is chosen equal to 1.
- When SCHEDULE (RUNTIME) is specified, the decision regarding iteration scheduling is deferred until runtime. The schedule type and chunk size can be chosen at runtime by setting the OMP_SCHEDULE environment variable. If this environment variable is not set, the resulting schedule is equivalent to SCHEDULE(STATIC).

SHARED

The **SHARED** clause specifies variables that must be available to all threads. If you specify a variable as **SHARED**, you are stating that all threads can safely share a single copy of the variable. When one or more variables are shared among all threads, all threads access the same storage area for the shared variables.

UNTIED

The **UNTIED** clause specifies that any thread in the team can resume the task region after a suspension.

Note

The thread number may change at any time during the execution of an untied task. Therefore, the value returned by `omp_get_thread_num` is generally not useful during execution of such a task region.

OpenMP Environment Variables

OpenMP environment variables allow you to control the behavior of OpenMP programs. These environment variables allow you to set and pass information that can alter the behavior of directives.

The PGI Compiler User's Guide contains a table that provides a brief summary of these variables. This section contains more information about each of them. For complete information and more details related to these environment variables, refer to the OpenMP documentation available on the WorldWide Web.

OMP_DYNAMIC

`OMP_DYNAMIC` currently has no effect. Typically this variable enables (**TRUE**) or disables (**FALSE**) the dynamic adjustment of the number of threads.

OMP_NESTED

`OMP_NESTED` currently has no effect. Typically this variable enables (**TRUE**) or disables (**FALSE**) nested parallelism.

OMP_MAX_ACTIVE_LEVELS

`OMP_MAX_ACTIVE_LEVELS` specifies the maximum number of nested parallel regions.

OMP_NUM_THREADS

`OMP_NUM_THREADS` specifies the number of threads to use during execution of parallel regions. The default value for this variable is 1. For historical reasons, the environment variable `NCPUS` is supported with the same functionality. In the event that both `OMP_NUM_THREADS` and `NCPUS` are defined, the value of `OMP_NUM_THREADS` takes precedence.

Note

`OMP_NUM_THREADS` defines the threads that are used to execute the program, regardless of the number of physical processors available in the system. As a result, you can run programs using more

threads than physical processors and they execute correctly. However, performance of programs executed in this manner can be unpredictable, and oftentimes will be inefficient.

OMP_SCHEDULE

OMP_SCHEDULE specifies the type of iteration scheduling to use for DO and PARALLEL DO loop directives that include the SCHEDULE(RUNTIME) clause, described in “[SCHEDULE,](#)” on page 102. The default value for this variable is STATIC.

If the optional chunk size is not set, a chunk size of 1 is assumed except in the case of a static schedule. For a static schedule, the default is as defined in “[DO..END DO ,](#)” on page 85.

Examples of the use of OMP_SCHEDULE are as follows:

```
% setenv OMP_SCHEDULE "STATIC, 5"
% setenv OMP_SCHEDULE "GUIDED, 8"
% setenv OMP_SCHEDULE "DYNAMIC"
```

OMP_STACKSIZE

OMP_STACKSIZE is an OpenMP 3.0 feature that controls the size of the stack for newly-created threads. This variable overrides the default stack size for a newly created thread. The value is a decimal integer followed by an optional letter B, K, M, or G, to specify bytes, kilobytes, megabytes, and gigabytes, respectively. If no letter is used, the default is kilobytes. There is no space between the value and the letter; for example, one megabyte is specified 1M. The following example specifies a stack size of 8 megabytes.

```
% setenv OMP_STACKSIZE 8M
```

The API functions related to OMP_STACKSIZE are `omp_set_stack_size` and `omp_get_stack_size`.

The environment variable OMP_STACKSIZE is read on program start-up. If the program changes its own environment, the variable is not re-checked.

This environment variable takes precedence over MPSTKZ. Once a thread is created, its stack size cannot be changed.

In the PGI implementation, threads are created prior to the first parallel region and persist for the life of the program. The stack size of the main thread (thread 0) is set at program start-up and is not affected by OMP_STACKSIZE.

OMP_THREAD_LIMIT

You can use the OMP_THREAD_LIMIT environment variable to specify the absolute maximum number of threads that can be used in a parallel program. Attempts to dynamically set the number of processes or threads to a higher value, for example using `set_omp_num_threads()`, cause the number of processes or threads to be set at the value of OMP_THREAD_LIMIT rather than the value specified in the function call.

OMP_WAIT_POLICY

OMP_WAIT_POLICY sets the behavior of idle threads - specifically, whether they spin or sleep when idle. The values are ACTIVE and PASSIVE, with ACTIVE the default. The behavior defined by OMP_WAIT_POLICY is also shared by threads created by auto-parallelization.

- Threads are considered idle when waiting at a barrier, when waiting to enter a critical region, or when unemployed between parallel regions.
- Threads waiting for critical sections always busy wait (ACTIVE).
- Barriers always busy wait (ACTIVE), with calls to `sched_yield` determined by the environment variable `MP_SPIN`.
- Unemployed threads during a serial region can either busy wait using the barrier (ACTIVE) or politely wait using a mutex (PASSIVE). This choice is set by `OMP_WAIT_POLICY`, so the default is ACTIVE.

When ACTIVE is set, idle threads consume 100% of their CPU allotment spinning in a busy loop waiting to restart in a parallel region. This mechanism allows for very quick entry into parallel regions, a condition which is good for programs that enter and leave parallel regions frequently.

When PASSIVE is set, idle threads wait on a mutex in the operating system and consume no CPU time until being restarted. Passive idle is best when a program has long periods of serial activity or when the program runs on a multi-user machine or otherwise shares CPU resources.

Chapter 4. PGI Accelerator Compilers Reference

The chapter “Using an Accelerator” in the PGI Compiler User’s Guide describes the programming model that uses a collection of compiler directives to specify regions of code in Fortran programs that can be offloaded from a *host* CPU to an attached *accelerator*. The method described provides a model for accelerator programming that is portable across operating systems and various types of host CPUs and accelerators.

PGI provides a set of Fortran accelerator compilers and tools for 64-bit x86-compatible processor-based workstations and servers with an attached NVIDIA CUDA-enabled GPU or Tesla card.

Note

The PGI Accelerator compilers require a separate license key in addition to a normal PGI Workstation, Server, or CDK license.

This chapter contains detailed descriptions of each of the PGI Accelerator directives that PGI supports. In addition, the section “[PGI Accelerator Directive Clauses](#),” on [page 113](#) contains information about the clauses associated with these directives.

PGI Accelerator Directives

This section provides detailed descriptions of the Fortran directives used to delineate accelerator regions and to augment information available to the compiler for scheduling of loops and classification of data.

PGI Accelerator directives are specified using special comments that are identified by a unique sentinel. This syntax enables compilers to ignore accelerator directives if support is disabled or not provided.

PGI currently supports these types of accelerator directives:

- An “[Accelerator Compute Region Directive](#)” defines information about the region of a program. These directives are either an accelerator compute region directive, that defines the region of a program to be compiled for execution on the accelerator device, or an accelerator data region directive that
- An “[Accelerator Loop Mapping Directive](#)” describes the type of parallelism to use to execute the loop and declare loop-private variables and arrays.

- A “[Combined Directive](#)” is a combination of the Accelerator region and loop mapping directives, and specifies a loop directive nested immediately inside an accelerator region directive.
- An “[Accelerator Declarative Data Directive](#)” specifies an array or arrays are to be allocated in the device memory for the duration of the implicit data region of a function, subroutine or program, and specifies whether the data values are to be transferred from the host to the device memory upon entry to the implicit data region, and from the device to the host memory upon exit from the implicit data region.
- An “[Accelerator Update Directive](#)” used within an explicit or implicit data region, updates all or part of a host memory array with values from the corresponding array in device memory, or updates all or part of a device memory array with values from the corresponding array in host memory.

Accelerator Compute Region Directive

This directive defines the region of the program that should be compiled for execution on an accelerator device.

Syntax

In Fortran, the syntax is:

```
!$acc region [clause [, clause]...]
    structured block
!$acc end region
```

where clause is one of the following, described in more detail in “[PGI Accelerator Directive Clauses](#)”:

```
if( condition )
copy( list )
copyin( list )
copyout( list )
local( list )
updatein( list )
updateout( list )
```

Description

Loops within the structured block are compiled into accelerator kernels. Data is copied from the host memory to the accelerator memory, as required, and result data is copied back. Any computation that cannot be executed on the accelerator, perhaps because of limitations of the device, is executed on the host. This approach may require data to move back and forth between the host and device.

At the end of the region, all results stored on the device that are needed on the host are copied back to the host memory, and accelerator memory is deallocated.

Restrictions

The following restrictions apply to the accelerator compute region directive:

- Accelerator regions may not be nested.
- A program may not branch into or out of an accelerator region.

- A program must not depend on the order of evaluation of the clauses, or on any side effects of the evaluations.
- At most one `if` clause may appear. In Fortran, the condition must evaluate to a scalar logical value.
- A variable may appear in only one of the `local`, `copy`, `copyin` or `copyout` lists.

Accelerator Data Region Directive

This directive defines data, typically arrays, that should be allocated in the device memory for the duration of the data region. Further, it defines whether data should be copied from the host to the device memory upon region entry, and copied from the device to host memory upon region exit.

Syntax

In Fortran, the syntax is:

```
!$acc data region [clause [, clause]...]
    structured block
!$acc end data region
```

where clause is one of the following, described in more detail in [“PGI Accelerator Directive Clauses”](#):

```
copy( list )
copyin( list )
copyout( list )
local( list )
mirror( list )
updatein( list )
updateout( list )
```

Description

Data is allocated in the device memory and copied from the host memory to the device, or copied back, as required. The *list* argument to each data clause is a comma-separated collection of variable names, array names, or subarray specifications. In all cases, the compiler allocates and manages a copy of the variable or array in device memory, creating a visible device copy of that variable or array.

In Fortran, a subarray is an array name followed by a comma-separated list of range specifications in parentheses, such as this:

```
arr(2:high,low:100)
```

If either the lower or upper bounds are missing, the declared or allocated bounds of the array, if known, are used. Using an array name in a data clause on a compute region directive without bounds tells the compiler to analyze the references to the array to determine what bounds to use. Thus, every array reference is equivalent to some subarray of that array.

Restrictions

The following restrictions apply to the accelerator data region directive:

- A variable, array, or subarray may appear at most once in all data clauses for a compute or data region.
- Only one subarray of an array may appear in all data clauses for a region.
- If a variable, array, or subarray appears in a data clause for a region, the same variable, array, or any subarray of the same array may not appear in a data clause for any enclosed region.
- In Fortran, the upper bound for the last dimension of an assumed-size dummy array must be specified.
- If a subarray is specified in a data clause, the compiler may choose to allocate memory for only that subarray on the accelerator.
- The compiler may pad dimensions of arrays on the accelerator to improve memory alignment and program performance.
- The mirror clause is valid only in Fortran. The *list* argument to the mirror clause, a comma-separated list of array names. The arrays may be explicit shape, assumed shape, or allocatable; pointer arrays are not allowed.
- In Fortran, pointer arrays may be specified, but pointer association is not preserved in the device memory.

Accelerator Loop Mapping Directive

An accelerator loop mapping directive specifies the type of parallelism to use to execute the loop and declare loop-private variables and arrays.

Syntax

In Fortran, the syntax of an accelerator loop mapping directive is

```
!$acc do [clause [,clause]...]
do loop
```

where clause is one of the following, described in more detail in [“PGI Accelerator Directive Clauses”](#):

```
cache (list)]
host [(width)]
independent
kernel
parallel [(width)]
private( list)
seq [(width)]
unroll [(width)]
vector [(width)]
```

Description

An accelerator loop mapping directive applies to a loop which must appear on the following line. It can describe what type of parallelism to use to execute the loop and declare loop-private variables and arrays.

Combined Directive

The combined accelerator region and loop mapping directive is a shortcut for specifying a loop directive nested immediately inside an accelerator region directive. The meaning is identical to explicitly specifying a region construct containing a loop directive. Any clause that is allowed in a region directive or a loop directive is allowed in a combined directive.

Syntax

In Fortran the syntax of the combined accelerator region and loop directive is:

```
!$acc region do [clause [, clause]...]
    do loop
```

where *clause* is any of the region or loop clauses described previously in this chapter.

The associated region is the body of the loop which must immediately follow the directive.

Restrictions

The following restrictions apply to a combined directive:

- The combined accelerator region and loop directive may not appear within the body of another accelerator region.
- All restrictions for the region directive and the loop directive apply.

Accelerator Declarative Data Directive

Declarative data directives specify that an array or arrays are to be allocated in the device memory for the duration of the implicit data region of a function, subroutine, or program. They also specify whether the data values are to be transferred from the host to the device memory upon entry to the implicit data region, and from the device to the host memory upon exit from the implicit data region.

You use the declarative data directives in the declaration section of a Fortran subroutine, function, or module.

These directives create a visible device copy of the variable or array.

Syntax

In Fortran the syntax of the declarative data directive is:

```
!$acc declclause [, declclause]...
```

where *declclause* is one of the following:

```
copy( list )
copyin( list )
copyout( list )
local( list )
mirror( list )
reflected( list )
```

Description

The associated region is the implicit region associated with the function, subroutine, or program in which the directive appears.

If the directive appears in a Fortran MODULE subprogram, the associated region is the implicit region for the whole program.

Restrictions

- A variable or array may appear at most once in all declarative data clauses for a function, subroutine, program, or module.
- Subarrays are not allowed in declarative data clauses.
- If variable or array appears in a declarative data clause, the same variable or array may not appear in a data clause for any region where the declaration of the variable is visible.
- In Fortran, assumed-size dummy arrays may not appear in declarative data clauses.
- The compiler may pad dimensions of arrays on the accelerator to improve memory alignment and program performance.
- The mirror and reflected clauses are valid only in Fortran.
- In Fortran, pointer arrays may be specified, but pointer association is not preserved in the device memory.

Accelerator Update Directive

The update directive is used within an explicit or implicit data region to do one of the following:

- Update all or part of a host memory array with values from the corresponding array in device memory.
- Update all or part of a device memory array with values from the corresponding array in host memory.

Syntax

In Fortran the syntax of the update data directive is:

```
!$acc update updateclause [, updateclause]...
```

where `updateclause` is one of the following:

```
host( list )
device( list )
```

Description

The effect of an update clause is to copy data from the device memory to the host memory for `updateout`, and from host memory to device memory for `updatein`. The following is true:

- The *list* argument to an update clause is a comma-separated collection of variable names, array names, or subarray specifications.
- Multiple subarrays of the same array may appear in a list.
- The updates are done in the order in which they appear on the directive.

Restrictions

These restrictions apply:

- The update directive is executable. It must not appear in place of the statement following a `logical if` in Fortran.
- A variable or array which appears in the list of an update directive must have a visible device copy.

PGI Accelerator Directive Clauses

Accelerator directives accept clauses that further clarify the use of the directive. Some of these clauses are specific to certain directives.

Accelerator Region Directive Clauses

The following clauses further clarify the use of the Accelerator Region directive.

if (condition)

The `if` clause is optional.

- When there is no `if` clause, the compiler generates code to execute as much of the region on the accelerator as possible.
- When an `if` clause appears, the compiler generates two copies of the region, one copy to execute on the accelerator and one copy to execute on the host. The condition in the `if` clause determines whether the host or accelerator copy is executed.
 - When the condition in the `if` clause evaluates to `.false.` in Fortran, the host copy is executed.
 - When the condition in the `if` clause evaluates to `.true.` in Fortran, the accelerator copy is executed.

Data Clauses

The data clauses for an accelerator region directive are one of the following:

```
copy( list )
copyout( list )
copyin( list )
local( list )
mirror( list )
updatein( list )
updateout( list )
```

Data clauses are optional, but may assist the compiler in generating code for an accelerator or in generating more optimal accelerator kernels.

Note

By default, the PGI Accelerator compilers attempt to minimize data movement between the host and accelerator. As a result, for many accelerator regions the compilers choose to copy sub-arrays which may be non-contiguous. Performance of an accelerator may improve in these cases if the user inserts explicit `copy/copyin/copyout` clauses on the accelerator region directive to specify to copy

whole arrays rather than sub-arrays. Depending on the architecture of the target accelerator memory, performance also may improve if one or more dimensions of copied arrays are padded.

For each variable or array used in the region that does not appear in any data clause, the compiler analyzes all references to the variable or array and determines:

- For arrays, how much memory needs to be allocated in the accelerator memory to hold the array;
- Whether the value in host memory needs to be copied to the accelerator memory;
- Whether a value computed on the accelerator will be needed again on the host, and therefore needs to be copied back to the host memory.

When compiler analysis is unable to determine these items, it may fail to generate code for the accelerator; in that case, it issues a message to notify the programmer why it failed. You can use data clauses to augment or override this compiler analysis.

List arguments

When a data clause is used, the *list* argument is a comma-separated collection of variable names, array names, or subarray specifications.

- Using an array name without bounds tells the compiler to use the whole array. Thus, every array reference is equivalent to some subarray of that array.
- In Fortran, a subarray is an array name followed by a comma-separated list of range specifications in parentheses, such as the following:

```
arr(2:high,low:100)
```

Array Restrictions

An accelerator region data clause has these restrictions related to arrays:

- If either the lower or upper bounds of an array are missing, the declared or allocated bounds of the array, if known, are used.
- In Fortran, the upper bound for the last dimension of an assumed-size dummy array must be specified.
- If a subarray is specified, then only that subarray of the array needs to be copied.
- Only one subarray for an array may appear in any data clause for a region.
- The compiler may pad dimensions of allocated arrays or subarrays to improve memory alignment and program performance.

copy (list)

You use the `copy` clause to declare that the variables, arrays or subarrays in the *list* have values in the host memory that need to be copied to the accelerator memory, and are assigned values on the accelerator that need to be copied back to the host.

- The data is copied to the device memory upon entry to the region.
- Data is copied back to the host memory upon exit from the region.

copyin (list)

You use the `copyin` clause to declare that the variables, arrays or subarrays in the *list* have values in the host memory that need to be copied to the accelerator memory.

- The data is copied to the device memory upon entry to the implicit region associated with the directive.
- If a variable, array, or subarray appears in a `copyin` clause then that data need not be copied back from the device memory to the host memory, even if those values were changed on the accelerator.

copyout (list)

You use the `copyout` clause to declare that the variables, arrays, or subarrays in the *list* are assigned or contain values in the accelerator memory that need to be copied back to the host memory.

- The data is copied back to the host memory upon exit from the region.
- If a variable, array or subarray appears in a `copyout` clause, then that data need not be copied to the device memory from the host memory, even if those values are used on the accelerator.

local (list)

You use the `local` clause to declare that the variables, arrays or subarrays in the *list* need to be allocated in the accelerator memory, but the values in the host memory are not needed on the accelerator, and the values computed and assigned on the accelerator are not needed on the host.

mirror (list)

You use the `mirror` clause to declare that the arrays in the list need to mirror the allocation state of the host array within the implicit region.

- If the host array is allocated upon region entry, the device copy of the array is allocated at region entry to the same size.
- If the host array is not allocated, the device copy is initialized to an unallocated state.
- If the host array is allocated or deallocated within the region, the device copy is allocated to the same size, or deallocated, at the same point in the region.
- If it is still allocated at region exit, the device copy is automatically deallocated.
- When used in a Fortran module subprogram, the associated region is the implicit region for the whole program.

Mirror Clause Restrictions

- The `mirror` clause is valid only in Fortran.
- The *list* argument to the `mirror` clause is a comma-separated list of array names. The arrays may be explicit shape, assumed shape, or allocatable; pointer arrays are not allowed.
- The `mirror` clause may be used for Fortran allocatable arrays in module subprograms; the `copy`, `copyin`, `copyout`, `local`, and `reflected` clauses may not be.

updatein|updateout (list)

The `update` clauses allow you to update values of variables, arrays, or subarrays.

- The *list* argument to each update clause is a comma-separated collection of variable names, array names, or subarray specifications.
- All variables or arrays that appear in the *list* argument of an update clause must have a visible device copy outside the compute or data region.
- Multiple subarrays of the same array may appear in update clauses for the same region, potentially causing updates of different subarrays in each direction.

updatein (list)

The `updatein` clause copies the variables, arrays, or subarrays in the *list* argument from host memory to the visible device copy of the variables, arrays, or subarrays in device memory, before beginning execution of the compute or data region.

updateout (list)

The `updateout` clause copies the visible device copies of the variables, arrays, or subarrays in the *list* argument to the associated host memory locations, after completion of the compute or data region.

Loop Scheduling Clauses

The loop scheduling clauses tell the compiler about loop level parallelism and how to map the parallelism onto the accelerator parallelism.

The loop scheduling clauses for the accelerator loop mapping directive are one of the following:

```
cache (list)]
host [(width)]
independent
kernel
parallel [(width)]
private( list )
seq [(width)]
unroll [(width)]
vector [(width)]
```

The loop scheduling clauses tell the compiler about loop level parallelism and how to map the parallelism onto the accelerator parallelism.

The loop scheduling clauses are optional.

For each loop without a scheduling clause, the compiler determines an appropriate schedule automatically.

loop scheduling clauses restrictions

The loop scheduling clauses have these restrictions:

- In some cases, there is a limit on the trip count of a parallel loop on the accelerator. For instance, some accelerators have a limit on the maximum length of a vector loop. In such cases, the compiler strip-mines the loop, so one of the loops has a maximum trip count that satisfies the limit.

For example, if the maximum vector length is 256, the compiler uses strip-mining to compile a vector loop like the following one:

```
!$acc do vector
do i = 1,n
```

into the following pair of loops:

```
do is = 1,n,256
  !$acc do vector
  do i = is,max(is+255,n)
```

The compiler then chooses an appropriate schedule for the outer, strip loop.

- If more than one scheduling clause appears on the loop directive, the compiler strip-mines the loop to get at least that many nested loops, applying one loop scheduling clause to each level.
- If a loop scheduling clause has a *width* argument, the compiler strip-mines the loop to that width, applying the scheduling clause to the outer strip or inner element loop, and then determines the appropriate schedule for the other loop.
- The *width* argument must be a compile-time positive constant integer.
- If two or more loop scheduling clauses appear on a single loop mapping directive, all but one must have a *width* argument.
- Some implementations or targets may require the *width* argument for the vector clause to be a compile-time constant.
- Some implementations or targets may require the *width* argument for the vector or parallel clauses to be a power of two, or a multiple of some power of two. If so, the behavior when the restriction is violated is implementation-defined.

loop scheduling clause examples

In the following example, the compiler strip-mines the loop to 16 host iterations:

```
!$acc do host(16), parallel
do i = 1,n
```

The parallel clause applies to the inner loop, as follows:

```
ns = ceil(n/16)
!$acc do host
do is = 1, n, ns
  !$acc do parallel
  do i = is, min(n,is+ns-1)
```

cache (list)

The `cache` clause provides a hint to the compiler to try to move the variables, arrays, or subarrays in the *list* to the highest level of the memory hierarchy.

Many accelerators have a software-managed fast cache memory, and the `cache` clause can help the compiler choose what data to keep in that fast memory for the duration of the loop. The compiler is not required to store all or even any of the data items in the cache memory.

host [(width)]

The `host` clause tells the compiler to execute the loop sequentially on the host processor. There is no maximum number of iterations on a host schedule. If the `host` clause has a *width* argument, the compiler strip mines the loop to that many strips, and determines an appropriate schedule for the remaining loop.

independent

The `independent` clause tells the compiler that the iterations of this loop are data-independent of each other. This allows the compiler to generate code to examine the iterations in parallel, without synchronization.

Note

It is an error to use the `independent` clause if any iteration writes to a variable or array element that any other iterations also writes or reads.

kernel

The `kernel` clause tells the compiler that the body of this loop is to be the body of the computational kernel. Any loops contained within the kernel loop are executed sequentially on the accelerator.

kernel clause restrictions

The `kernel` clause has this restriction:

- Loop mapping directives must not appear on any loop contained within the kernel loop.

parallel [(width)]

The `parallel` clause tells the compiler to execute this loop in parallel mode on the accelerator. There may be a target-specific limit on the number of iterations in a parallel loop or on the number of parallel loops allowed in a given kernel. If there is a limit:

- If there is no *width* argument, or the value of the *width* argument is greater than the limit, the compiler enforces the limit.
- If there is a *width* argument or a limit on the number of iterations in a parallel loop, then only that many iterations can run in parallel at a time.

private (list)

You use the `private` clause to declare that the variables, arrays, or subarrays in the *list* argument need to be allocated in the accelerator memory with one copy for each iteration of the loop.

Any value of the variable or array used in the loop must have been computed and assigned in that iteration of the loop, and the values computed and assigned in any iteration are not needed after completion of the loop.

Using an array name without bounds tells the compiler to analyze the references to the array to determine what bounds to use. If the lower or upper bounds are missing, the declared or allocated bounds, if known, are used.

private clause restrictions

The `private` clause has these restrictions:

- A variable, array or subarray may only appear once in any `private` clause for a loop.
- Only one subarray for an array may appear in any `private` clause for a loop.
- If a subarray appears in a `private` clause, then the compiler only needs to allocate memory to hold that subarray in the accelerator memory.
- The compiler may pad dimensions of allocated arrays or subarrays to improve memory alignment and program performance.
- If a subarray appears in a `private` clause, it is an error to refer to any element of the array in the loop outside the bounds of the subarray.
- It is an error to refer to a variable or any element of an array or subarray that appears in a `private` clause and that has not been assigned in this iteration of the loop.
- In Fortran, the upper bound for the last dimension of an assumed-size dummy array must be specified.

seq [(width)]

The `seq` clause tells the compiler to execute this loop sequentially on the accelerator. There is no maximum number of iterations for a `seq` schedule. If the `seq` clause has a *width* argument, the compiler strip mines the loop and determines an appropriate schedule for the remaining loop.

unroll [(width)]

The `unroll` clause tells the compiler to unroll *width* iterations for sequential execution on the accelerator. The *width* argument must be a compile time positive constant integer.

unroll clause restrictions

The `unroll` clause has these restrictions:

- If two or more loop scheduling clauses appear on a single loop mapping directive, all but one must have a *width* argument.
- Some implementations or targets may require the *width* expression for the vector clause to be a compile-time constant.
- Some implementations or targets may require the *width* expression for the vector or parallel clauses to be a power of two, or a multiple of some power of two. If this is the case, the behavior when the restriction is violated is implementation-defined.

vector [(width)]

The `vector` clause tells the compiler to execute this loop in vector mode on the accelerator. There may be a target-specific limit on the number of iterations in a vector loop, the aggregate number of iterations in all vector loops, or the number of vector loops allowed in a kernel.

When there is a limit:

- If there is no *width* argument, or the value of the *width* argument is greater than the limit, the compiler strip mines the loop to enforce the limit.

Declarative Data Directive Clauses

The clauses for a declarative data directive are one of the following:

```
copy( list )
copyout( list )
copyin( list )
local( list )
mirror( list )
reflected( list )
```

All of these clauses, except the `reflected(list)` clause are the same as the clauses defined for the accelerator region directive.

reflected (list)

You use the `reflected` clause to declare that the actual argument arrays that are bound to the dummy argument arrays in the *list* need to have a visible copy at the call site.

- This clause is only valid in a Fortran subroutine or function.
- The *list* argument to the `reflected` clause is a comma-separated list of dummy argument array names. The arrays may be explicit shape, assumed shape, or allocatable.
- If the `reflected` declarative clause is used, the caller must have an explicit interface to this subprogram.
- If a Fortran interface block is used to describe the explicit interface, a matching `reflected` directive must appear in the interface block.
- The device copy of the array used within the subroutine or function is the device copy that is visible at the call site.

Update Directive Clauses

The clauses for an accelerator update directive are one of the following:

```
device( list )
host( list )
```

The *list* argument to each update clause is a comma-separated collection of variable names, array names, or subarray specifications. All variables or arrays that appear in the *list* argument of an update clause must have a visible device copy outside the compute or data region.

Multiple subarrays of the same array may appear in update clauses for the same region, potentially causing updates of different subarrays in each direction.

device (list)

The `device` clause for the update directive copies the variables, arrays, or subarrays in the *list* argument from host memory to the visible device copy of the variables, arrays, or subarrays in device memory. The copy occurs before beginning execution of the compute or data region.

This clause has the same function as the `updatein` clause for an accelerator compute region directive.

host (list)

The `host` clause for the `update` directive copies the visible device copies of the variables, arrays, or subarrays in the *list* argument to the associated host memory locations. The copy occurs after completion of the compute or data region.

This clause has the same function as the `updateout` clause for an accelerator compute region directive.

PGI Accelerator Runtime Routines

This section defines specific details related to user-callable functions and library routines that are available for use by programmers to query the accelerator features and to control behavior of accelerator-enabled programs at runtime.

To access these routines, add the following to your program:

For a Fortran program:

```
use accel_lib
```

For a C program:

```
#include "accel.h"
```

acc_allocs

The `acc_allocs` routine returns the number of arrays allocated in data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer function acc_allocs()
```

Description

A call to `acc_allocs` returns the number of arrays allocated on the accelerator by data or compute regions since the start of the program.

acc_bytesalloc

The `acc_bytesalloc` routine returns the total bytes allocated by data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_bytesalloc()
```

Description

A call to `acc_bytesalloc` returns the total bytes allocated by data or compute regions since the start of the program.

Important

This is not the bytes currently allocated on the device.

acc_bytesin

The `acc_bytesin` routine returns the total bytes copied in to the accelerator by data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_bytesin()
```

Description

A call to `acc_bytesin` returns the total bytes copied in to the accelerator by data or compute regions since the start of the program. This total includes data implicitly copied through compiler analysis as well as copies directed by the user through the use of `copy`, `copyin`, or `updatein` clauses, or `update device` directives.

acc_bytesout

The `acc_bytesout` routine returns the total bytes copied out from the accelerator by data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_bytesout()
```

Description

A call to `acc_bytesout` returns the total bytes copied out from the accelerator by data or compute regions since the start of the program. This total includes data implicitly copied through compiler analysis as well as copies directed by the user through the use of `copy`, `copyin`, or `updatein` clauses, or `update host` directives.

acc_copyins

The `acc_copyins` routine returns the number of arrays copied in to the accelerator by data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer function acc_copyins()
```

Description

A call to `acc_copyins` returns the number of arrays copied in to the accelerator by data or compute regions since the start of the program. This number is the count of arrays, not the number of DMA copies from the

host memory to the device memory. The number includes arrays implicitly copied through compiler analysis as well as copies directed by the user through the use of `copy`, `copyin`, or `updatein` clauses, or update device directives.

acc_copyouts

The `acc_copyouts` routine returns the number of arrays copied out from the accelerator by data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer function acc_copyouts()
```

Description

A call to `acc_copyouts` returns the number of arrays copied out from the accelerator by data or compute regions since the start of the program. This number is the count of arrays, not the number of DMA copies from the device memory to the host memory. The number includes arrays implicitly copied through compiler analysis as well as copies directed by the user through the use of `copy`, `copyin`, or `updatein` clauses, or update host directives.

acc_disable_time

The `acc_disable_time` routine tells the runtime to stop profiling accelerator regions and kernels.

Syntax

In Fortran, the syntax is this:

```
subroutine acc_disable_time( devicetype )
integer(acc_device_kind) devicetype
```

Description

The `acc_disable_time` routine decrements the profile counter in the runtime. If the profile counter reaches zero, accelerator region and kernel profiling is disabled.

This routine is only implemented when the argument has the value `acc_device_nvidia`. If the program is linked with `-ta=nvidia,time`, an implicit call to `acc_enable_time(acc_device_nvidia)` is made at program startup. A subsequent call to `acc_disable_time(acc_device_nvidia)` disables that profiling.

acc_enable_time

The `acc_enable_time` routine tells the runtime to start profiling accelerator regions and kernels, if it is not already doing so.

Syntax

In Fortran, the syntax is this:

```
subroutine acc_enable_time( devicetype )
integer(acc_device_kind) devicetype
```

Description

The `acc_enable_time` routine increments the profile counter in the runtime. If the profile counter is greater than zero, accelerator region and kernel profiling is enabled.

This routine is only implemented when the argument has the value `acc_device_nvidia`. If the program is linked with `-ta=nvidia,time`, an implicit call to `acc_enable_time(acc_device_nvidia)` is made at program startup.

acc_exec_time

The `acc_exec_time` routine returns the number of microseconds spent on the accelerator executing kernels.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_exec_time( devicetype )
integer(acc_device_kind) devicetype
```

Description

A call to `acc_exec_time` returns the number of microseconds spent since the program started on the accelerator executing kernels while accelerator profiling was active. This routine is only implemented when the argument has the value `acc_device_nvidia`.

acc_frees

The `acc_frees` routine returns the number of arrays freed or deallocated in data or compute regions.

Syntax

In Fortran, the syntax is this:

```
integer function acc_frees()
```

Description

A call to `acc_frees` returns the number of arrays freed on the accelerator at the end of data or compute regions since the start of the program. Outside of all accelerator regions, the value returned by `acc_frees` should equal the value returned by `acc_allocs`.

acc_get_device

The `acc_get_device` routine returns the type of accelerator device being used.

Syntax

In Fortran, the syntax is this:

```
integer function acc_get_device()
```

Description

The `acc_get_device` routine returns the type of accelerator device to use when executing an accelerator compute region. Its return value is one of the predefined values in the Fortran include file `accel_lib.h` or the Fortran module `accel_lib`.

This routine is useful when a program is compiled to use more than one type of accelerator.

Restrictions

The `acc_get_device` routine has the following restrictions:

- The routine may not be called during execution of an accelerator compute or data region.
- If the device type has not yet been selected, the value `acc_device_none` is returned.

`acc_get_device_num`

The `acc_get_device_num` routine returns the number of the device being used to execute an accelerator region.

Syntax

In Fortran, the syntax is this:

```
integer function acc_get_device_num(devicetype)
integer(acc_device_kind) devicetype
```

Description

The `acc_get_device_num` routine returns the number of the device being used to execute an accelerator region.

Restrictions

The `acc_get_device_num` routine has the following restrictions:

- The routine may not be called during execution of an accelerator compute or data region.
- If the device has not yet been selected, the value `-1` is returned.
- The argument must have the value `acc_device_nvidia`.

`acc_get_free_memory`

The `acc_get_free_memory` routine returns the total available memory on the attached accelerator.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_get_free_memory()
```

Description

A call to `acc_get_free_memory` returns the total memory on the attached accelerator. This routine must have been preceded by a call to `acc_init`, or by an accelerator region that initializes the device.

acc_get_memory

The `acc_get_memory` routine returns the total memory on the attached accelerator.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_get_free_memory()
```

Description

A call to `acc_get_free_memory` returns the total memory on the attached accelerator. This routine must have been preceded by a call to `acc_init`, or by an accelerator region that initializes the device.

acc_get_num_devices

The `acc_get_num_devices` routine returns the number of accelerator devices of the given type attached to the host.

Syntax

In Fortran, the syntax is this:

```
integer function acc_get_num_devices(devicetype)
integer(acc_device_kind) devicetype
```

Description

The `acc_get_num_devices` routine returns the number of accelerator devices of the given type attached to the host. The *devicetype* argument determines what kind of device to count. The possible values for *devicetype* are implementation-specific, and are listed in the Fortran include file `accel_lib.h` and the Fortran module `accel_lib`.

acc_init

The `acc_init` routine connects to and initializes the accelerator device and allocates the control structures in the accelerator library.

Syntax

In Fortran, the syntax is this:

```
subroutine acc_init( devicetype )
integer(acc_device_kind) devicetype
```

Description

The `acc_init` routine connects to and initializes the accelerator device and allocates the control structures in the accelerator library.

Restrictions

The `acc_init` routine has the following restrictions:

- The `acc_init` routine must be called before entering any accelerator regions or after an `acc_shutdown` call.
- The argument must be one of the predefined values in the Fortran include file `accel_lib.h` or the Fortran module `accel_lib`.
- The routine may not be called during execution of an accelerator region.
- If the device type specified is not available, the behavior is implementation-defined; in particular, the program may abort.
- If the routine is called more than once with a different value for the device type argument and without an intervening `acc_shutdown` call, the behavior is implementation-defined.
- If some accelerator regions are compiled to only use one device type, calling this routine with a different device type may produce undefined behavior.

acc_kernels

The `acc_kernels` routine returns the number of accelerator kernels launched since the start of the program.

Syntax

In Fortran, the syntax is this:

```
integer function acc_kernels()
```

Description

A call to `acc_kernels` returns the number of accelerator kernels launched since the start of the program.

acc_on_device

The `acc_on_device` routine tells the program whether it is executing on a particular device.

Syntax

In Fortran, the syntax is this:

```
logical function acc_on_device( devicetype )
  integer(acc_device_kind) devicetype
```

Description

The `acc_on_device` routine may be used to execute different paths depending on whether the code is running on the host or on some accelerator.

- If the `acc_on_device` routine has a compile-time constant argument, it evaluates at compile time to a constant. The argument must be one of the defined accelerator types.
- If `acc_on_device` has the argument `acc_device_host`, then outside of an accelerator compute region, or in an accelerator compute region that is compiled for the host processor, this routine evaluates to `.true.` for Fortran; otherwise, it evaluates to `.false.` for Fortran.

acc_regions

The `acc_regions` routine returns the number of accelerator data and compute regions entered since the start of the program.

Syntax

In Fortran, the syntax is this:

```
integer function acc_regions()
```

Description

A call to `acc_regions` returns the number of accelerator data and compute regions entered since the start of the program.

acc_set_device

The `acc_set_device` routine specifies which type of device the runtime uses when executing an accelerator compute region.

Syntax

In Fortran, the syntax is this:

```
subroutine acc_set_device( devicetype )
integer(acc_device_kind) devicetype
```

Description

The `acc_set_device` routine specifies which type of device the runtime uses when executing an accelerator compute region. This is useful when the program has been compiled to use more than one type of accelerator.

Restrictions

The `acc_set_device` routine has the following restrictions:

- The routine may not be called during execution of an accelerator compute or data region.
- If the device type specified is not available, the behavior is implementation-defined; in particular, the program may abort.
- If the routine is called more than once with a different value for the device type argument and without an intervening `acc_shutdown` call, the behavior is implementation-defined.
- If some accelerator regions are compiled to only use one device type, calling this routine with a different device type may produce undefined behavior.

acc_set_device_num

The `acc_set_device_num` routine tells the runtime which device to use when executing an accelerator region.

Syntax

In Fortran, the syntax is this:

```
subroutine acc_set_device_num( devicenum, devicetype )
  integer devicenum
  integer(acc_device_kind) devicetype
```

Description

The `acc_set_device_num` routine tells the runtime which device to use among those attached of the given type.

- If the value of `devicenum` is zero, the runtime reverts to its default behavior, which is implementation-defined.
- If the value of `devicenum` is greater than the value returned by `acc_get_num_devices` for that device type, the behavior is implementation-defined.
- If the value of the second argument is zero, the selected device number is used for all attached accelerator types.
- Calling `acc_set_device_num` implies a call to `acc_set_device` with the `devicetype` specified by this routine.

Restrictions

The `acc_set_device_num` routine has the following restrictions:

- The routine may not be called during execution of an accelerator region.

acc_shutdown

The `acc_shutdown` routine tells the runtime to shutdown the connection to the given accelerator device, and free up any runtime resources.

Syntax

In Fortran, the syntax is this:

```
subroutine acc_shutdown( devicetype )
  integer(acc_device_kind) devicetype
```

Description

The `acc_shutdown` routine disconnects the program from the accelerator device, and frees up any runtime resources. If the program is built to run on different device types, you can use this routine to connect to a different device.

Restrictions

The `acc_shutdown` routine has the following restrictions:

- The routine may not be called during execution of an accelerator region.

acc_total_time

The `acc_total_time` routine returns the number of microseconds spent in accelerator compute regions and moving data for accelerator data regions.

Syntax

In Fortran, the syntax is this:

```
integer(8) function acc_total_time( devicetype()
integer(acc_device_kind) devicetype
```

Description

A call to `acc_total_time` returns the number of microseconds spent since the program started in computer regions or in transferring data to and from the accelerator while accelerator profiling was active. This routine is only implemented when the argument has the value `acc_device_nvidia`.

Accelerator Environment Variables

This section describes the environment variables that PGI supports to control behavior of accelerator-enabled programs at execution and to modify the behavior of accelerator regions. The following are TRUE for all these variables:

- The names of the environment variables must be upper case.
- The values assigned environment variables are case insensitive and may have leading and trailing white space.
- The behavior is implementation-defined if the values of the environment variables change after the program has started, even if the program itself modifies the values.

ACC_DEVICE

The `ACC_DEVICE` environment variable controls the default device type to use when executing accelerator regions, if the program has been compiled to use more than one different type of device. The value of this environment variable is implementation-defined.

When a program is compiled with the PGI Unified Binary, the `ACC_DEVICE` environment variable controls the default device to use when executing a program. The value of this environment variable must be set to `NVIDIA` or `nvidia`, indicating to run on the NVIDIA GPU. Currently, any other value of the environment variable causes the program to use the host version.

Example

The following example indicates to use the NVIDIA GPU when executing the program:

```
setenv ACC_DEVICE nvidia
export ACC_DEVICE=nvidia
```

ACC_DEVICE_NUM

The `ACC_DEVICE_NUM` environment variable controls the default device number to use when executing accelerator regions. The value of this environment variable must be a nonnegative integer between zero and the number of devices attached to the host.

- If the value is zero, the implementation-defined default is used.
- If the value is greater than the number of devices attached, the behavior is implementation-defined.

Example

The following example indicates how to set the default device number to use when executing accelerator regions:

```
setenv ACC_DEVICE_NUM 1
export ACC_DEVICE_NUM=1
```

ACC_NOTIFY

The `ACC_NOTIFY` environment variable, when set to a non-negative integer, indicates to print a short message to the standard output when a kernel is executed on an accelerator. The value of this environment variable must be a nonnegative integer.

- If the value is zero, no message is printed (the default behavior).
- If the value is nonzero, a one-line message is printed whenever an accelerator kernel is executed.

Example

The following example indicates to print a message for each kernel launched on the device:

```
setenv ACC_NOTIFY 1
export ACC_NOTIFY=1
```

pgcudainit Utility

PGI includes a utility program **pgcudainit**. If you run this program in background mode, it holds open a CUDA connection to the device driver, significantly reducing initialization time for subsequent programs.

Chapter 5. Directives Reference

PGI Fortran compilers support proprietary directives. These directives override corresponding command-line options. For usage information such as the scope and related command-line options, refer to the PGI Compiler User's Guide.

This chapter contains detailed descriptions of PGI's proprietary directives.

PGI Proprietary Fortran Directive Summary

Directives are Fortran comments that the user may supply in a source file to provide information to the compiler. These comments alter the effects of certain command line options or default behavior of the compiler. They provide pragmatic information that control the actions of the compiler in a particular portion of a program without affecting the program as a whole. That is, while a command line option affects the entire source file that is being compiled, directives apply, or disable, the effects of a command line option to selected subprograms or to selected loops in the source file, for example, to optimize a specific area of code. Use directives to tune selected routines or loops.

The Fortran directives may have any of the following forms:

```
!pgi$g directive  
!pgi$r directive  
!pgi$l directive  
!pgi$ directive
```

where the scope indicator follows the \$ and is either g (global), r (routine), or l (loop). This indicator controls the scope of the directive, though some directives ignore the scope indicator.

Note

If the input is in fixed format, the comment character, !, * or C, must begin in column 1.

Directives override corresponding command-line options. For usage information such as the scope and related command-line options, refer to the "Using Directives and Pragmas in the PGI Compiler User's Guide."

altcode (noaltcode)

The `altcode` directive instructs the compiler to generate alternate code for vectorized or parallelized loops.

The `noaltcode` directive disables generation of alternate code.

Scope: This directive affects the compiler only when `-Mvect=sse` or `-Mconcur` is enabled on the command line.

cpgi\$ altcode

Enables alternate code (`altcode`) generation for vectorized loops. For each loop the compiler decides whether to generate `altcode` and what type(s) to generate, which may be any or all of: `altcode` without iteration peeling, `altcode` with non-temporal stores and other data cache optimizations, and `altcode` based on array alignments calculated dynamically at runtime. The compiler also determines suitable loop count and array alignment conditions for executing the alternate code.

cpgi\$ altcode alignment

For a vectorized loop, if possible, generates an alternate vectorized loop containing additional aligned moves which is executed if a runtime array alignment test is passed.

cpgi\$ altcode [(n)] concur

For each auto-parallelized loop, generates an alternate serial loop to be executed if the loop count is less than or equal to `n`. If `n` is omitted or `n` is 0, the compiler determines a suitable value of `n` for each loop.

cpgi\$ altcode [(n)] concurreduction

Sets the loop count threshold for parallelization of reduction loops to `n`. For each auto-parallelized reduction loop, generate an alternate serial loop to be executed if the loop count is less than or equal to `n`. If `n` is omitted or `n` is 0, the compiler determines a suitable value of `n` for each loop.

cpgi\$ altcode [(n)] nontemporal

For a vectorized loop, if possible, generates an alternate vectorized loop containing non-temporal stores and other cache optimizations to be executed if the loop count is greater than `n`. If `n` is omitted or `n` is 1, the compiler determines a suitable value of `n` for each loop. The alternate code is optimized for the case when the data referenced in the loop does not all fit in level 2 cache.

cpgi\$ altcode [(n)] nopeel

For a vectorized loop where iteration peeling is performed by default, if possible, generates an alternate vectorized loop without iteration peeling to be executed if the loop count is less than or equal to `n`. If `n` is omitted or `n` is 1, the compiler determines a suitable value of `n` for each loop, and in some cases it may decide not to generate an alternate unpeeled loop.

cpgi\$ altcode [(n)] vector

For each vectorized loop, generates an alternate scalar loop to be executed if the loop count is less than or equal to `n`. If `n` is omitted or `n` is 1, the compiler determines a suitable value of `n` for each loop.

cpgi\$ noaltcode

Sets the loop count thresholds for parallelization of all innermost loops to 0, and disables alternate code generation for vectorized loops.

assoc (noassoc)

This directive toggles the effects of the `-Mvect=noassoc` command-line option, an optimization `-M` control.

Scope: This directive affects the compiler only when `-Mvect=sse` is enabled on the command line.

By default, when scalar reductions are present the vectorizer may change the order of operations, such as dot product, so that it can generate better code. Such transformations may change the result of the computation due to roundoff error. The `noassoc` directive disables these transformations.

bounds (nobounds)

This directive alters the effects of the `-Mbounds` command line option. This directive enables the checking of array bounds when subscripted array references are performed. By default, array bounds checking is not performed.

cncall (nocncall)

This directive indicates that loops within the specified scope are considered for parallelization, even if they contain calls to user-defined subroutines or functions. A `nocncall` directive cancels the effect of a previous `cncall`.

concur (noconcur)

This directive alters the effects of the `-Mconcur` command-line option. The directive instructs the auto-parallelizer to enable auto-concurrentization of loops.

Scope: This directive affects the compiler only when `-Mconcur` is enabled on the command line.

If `concur` is specified, the compiler uses multiple processors to execute loops which the auto-parallelizer determines to be parallelizable. The `noconcur` directive disables these transformations; however, use of `concur` overrides previous `noconcur` statements.

depchk (nodepchk)

This directive alters the effects of the `-Mdepchk` command line option. When potential data dependencies exist, the compiler, by default, assumes that there is a data dependence that in turn may inhibit certain optimizations or vectorizations. `nodepchk` directs the compiler to ignore unknown data dependencies.

eqvchk (noeqvchk)

The `eqvchk` directive specifies to check dependencies between EQUIVALENCE associated elements. When examining data dependencies, `noeqvchk` directs the compiler to ignore any dependencies between variables appearing in EQUIVALENCE statements.

invarif (noinvarif)

This directive has no corresponding command-line option. Normally, the compiler removes certain invariant if constructs from within a loop and places them outside of the loop. The directive `noinvarif` directs the compiler not to move such constructs. The directive `invarif` toggles a previous `noinvarif`.

ivdep

The `ivdep` directive assists the compiler's dependence analysis and is equivalent to the directive `nodepchk`.

lstval (nolstval)

This directive has no corresponding command-line option. The compiler determines whether the last values for loop iteration control variables and promoted scalars need to be computed. In certain cases, the compiler must assume that the last values of these variables are needed and therefore computes their last values. The directive `nolstval` directs the compiler not to compute the last values for those cases.

prefetch

The `prefetch` directive the compiler emits prefetch instructions whereby elements are fetched into the data cache prior to first use. By varying the prefetch distance, it is sometimes possible to reduce the effects of main memory latency and improve performance.

The syntax of this directive is:

```
c$mem prefetch <var1>[,<var2>[,...]]
```

where `<varn>` is any valid variable, member, or array element reference.

opt

The `opt` directive overrides the value specified by the command line option `-On`.

The syntax of this directive is:

```
cpgi$<scope> opt=<level>
```

where the optional `<scope>` is *r* or *g* and `<level>` is an integer constant representing the optimization level to be used when compiling a subprogram (routine scope) or all subprograms in a file (global scope).

safe_lastval

During parallelization, scalars within loops need to be privatized. Problems are possible if a scalar is accessed outside the loop. If you know that a scalar is assigned on the last iteration of the loop, making it safe to parallelize the loop, you use the `safe_lastval` directive to let the compiler know the loop is safe to parallelize.

For example, use the following C pragma to tell the compiler that for a given loop the last value computed for all scalars make it safe to parallelize the loop:

```
cpgi$1 safe_lastval
#pragma loop safe_lastval
```

The command-line option `-Msafe_lastval` provides the same information for all loops within the routines being compiled, essentially providing global scope.

In the following example, the value of t may not be computed on the last iteration of the loop.

```
do i = 1, N
  if( f(x(i)) > 5.0 then)
    t = x(i)
  endif
enddo
v = t
```

If a scalar assigned within a loop is used outside the loop, we normally save the last value of the scalar. Essentially the value of the scalar on the "last iteration" is saved, in this case when $i=N$.

If the loop is parallelized and the scalar is not assigned on every iteration, it may be difficult to determine on what iteration t is last assigned, without resorting to costly critical sections. Analysis allows the compiler to determine if a scalar is assigned on every iteration, thus the loop is safe to parallelize if the scalar is used later. An example loop is:

```
do i = 1, N
  if( x(i) > 0.0 ) then
    t = 2.0
  else
    t = 3.0
  endif
  y(i) = ...t...
enddo
v = t
```

where t is assigned on every iteration of the loop. However, there are cases where a scalar may be privatizable. If it is used after the loop, it is unsafe to parallelize. Examine this loop:

```
do i = 1,N
  if( x(i) > 0.0 ) then
    t = x(i)
    ...
    ...
  y(i) = ...t..
  endif
enddo
v = t
```

where each use of t within the loop is reached by a definition from the same iteration. Here t is privatizable, but the use of t outside the loop may yield incorrect results since the compiler may not be able to detect on which iteration of the parallelized loop t is assigned last.

The compiler detects these cases. When a scalar is used after the loop, but is not defined on every iteration of the loop, parallelization does not occur.

tp

You use the directive `tp` to specify one or more processor targets for which to generate code.

```
cpgi$ tp [target]...
```

Note

The `tp` directive can only be applied at the routine or global level.

Refer to the PGI Workstation Release Notes for a list of targets that can be used as parameters to the `tp` directive.

unroll (nounroll)

The `unroll` directive enables loop unrolling while `nounroll` disables loop unrolling.

Note

The `unroll` directive has no effect on vectorized loops.

The directive takes arguments `c` and `n`.

- `c` specifies that `c` complete unrolling should be turned on or off.
- `n` specifies that `n` (count) unrolling should be turned on or off. In addition, the following arguments may be added to the `unroll` directive:

In addition, the following arguments may be added to the `unroll` directive:

`c:v` sets the threshold to which `c` unrolling applies. `v` is a constant; and a loop whose constant loop count is less than or equal to (\leq) `v` is completely unrolled.

```
cpgi$ unroll = c:v
```

`n:v` adjusts threshold to which `n` unrolling applies. `v` is a constant. A loop to which `n` unrolling applies is unrolled `v` times.

```
cpgi$ unroll = n:v
```

The directives `unroll` and `nounroll` only apply if `-Munroll` is selected on the command line.

vector (novector)

The directive `novector` disables vectorization. The directive `vector` re-enables vectorization after a previous `novector` directive. The directives `vector` and `novector` only apply if `-Mvect` has been selected on the command line.

vintr (novintr)

The directive `novintr` directs the vectorizer to disable recognition of vector intrinsics. The directive `vintr` re-enables recognition of vector intrinsics after a previous `novintr` directive. The directives `vintr` and `novintr` only apply if `-Mvect` has been selected on the command line.

Prefetch Directives

Prefetch instructions can increase the speed of an application substantially by bringing data into cache so that it is available when the processor needs it. The PGI prefetch directive takes the form:

The syntax of a prefetch directive is as follows:

```
c$mem prefetch <var1>[,<var2>[,...]]
```

where `<varn>` is any valid variable, member, or array element reference.

For examples on how to use the prefetch directive, refer to the PGI Compiler User's Guide.

!DEC\$ Directives

PGI Fortran compilers for Microsoft Windows support directives that help with inter-language calling and importing and exporting routines to and from DLLs. These directives all take the form:

```
!DEC$ directive
```

For specific format requirements, refer to the section “!DEC\$ Directives” in the PGI Compiler User's Guide.

ALIAS Directive

This directive specifies an alternative name with which to resolve a routine.

The syntax for the ALIAS directive is either of the following:

```
!DEC$ ALIAS routine_name , external_name  
!DEC$ ALIAS routine_name : external_name
```

In this syntax, `external_name` is used as the external name for the specified `routine_name`.

If `external_name` is an identifier name, the name (in uppercase) is used as the external name for the specified `routine_name`. If `external_name` is a character constant, it is used as-is; the string is not changed to uppercase, nor are blanks removed.

You can also supply an alias for a routine using the ATTRIBUTES directive, described in the next section:

```
!DEC$ ATTRIBUTES ALIAS : 'alias_name' :: routine_name
```

This directive specifies an alternative name with which to resolve a routine, as illustrated in the following code fragment that provides external names for three routines. In this fragment, the external name for `sub1` is `name1`, for `sub2` is `name2`, and for `sub3` is `name3`.

```
subroutine sub  
!DEC$ alias sub1 , 'name1'  
!DEC$ alias sub2 : 'name2'  
!DEC$ attributes alias : 'name3' :: sub3
```

ATTRIBUTES Directive

This directive lets you specify properties for data objects and procedures.

The syntax for the ATTRIBUTES directive is this:

```
!DEC$ ATTRIBUTES <list>
```

where <list> is one of the following:

ALIAS : 'alias_name' :: routine_name

Specifies an alternative name with which to resolve routine_name.

C :: routine_name

Specifies that the routine routine_name will have its arguments passed by value. When a routine marked C is called, arguments, except arrays, are sent by value. For characters, only the first character is passed. The standard Fortran calling convention is pass by reference.

DLLEXPORT :: name

Specifies that name is being exported from a DLL.

DLLIMPORT :: name

Specifies that name is being imported from a DLL.

NOMIXED_STR_LEN_ARG

Specifies that hidden lengths are placed in sequential order at the end of the list, like -Miface=unix.

Note

This attribute only applies to routines that are CREF-style or that use the default Windows calling conventions.

REFERENCE :: name

Specifies that the argument name is being passed by reference. Often this attribute is used in conjunction with STDCALL, where STDCALL refers to an entire routine; then individual arguments are modified with REFERENCE.

STDCALL :: routine_name

Specifies that routine routine_name will have its arguments passed by value. When a routine marked STDCALL is called, arguments (except arrays and characters) will be sent by value. The standard Fortran calling convention is pass by reference.

VALUE :: name

Specifies that the argument 'name' is being passed by value.

DECORATE Directive

The DECORATE directive specifies that the name specified in the ALIAS directive should have the prefix and postfix decorations performed on it that are associated with the calling conventions that are in effect. These declarations are the same ones performed on the name when ALIAS is not specified.

The syntax for the DECORATE directive is this:

```
!DEC$ DECORATE
```

Note

When ALIAS is not specified, this directive has no effect.

DISTRIBUTE Directive

This directive is front-end based, and tells the compiler at what point within a loop to split into two loops.

The syntax for the DISTRIBUTE directive is either of the following:

```
!DEC$ DISTRIBUTE POINT  
!DEC$ DISTRIBUTEPOINT
```

Example:

```
subroutine dist(a,b,n)  
  integer i  
  integer n  
  integer a(*)  
  integer b(*)  
  do i = 1,n  
    a(i) = a(i)+2  
    !DEC$ DISTRIBUTE POINT  
    b(i) = b(i)*4  
  enddo  
end subroutine
```

IGNORE_TKR Directive

This directive indicates to the compiler to ignore the type, kind, and/or rank of the specified dummy arguments in an interface of a procedure. The compiler also ignores the type, kind, and/or rank of the actual arguments when checking all the specifics in a generic call for ambiguities.

The syntax for the IGNORE_TKR directive is this:

```
!DIR$ IGNORE_TKR [ [(<letter>) <dummy_arg>] ... ]
```

<letter>

is one or any combination of the following:

T - type

K - kind

R - rank

For example, KR indicates to ignore both kind and rank rules and TKR indicates to ignore the type, kind, and rank arguments.

<dummy_arg>

if specified, indicates the dummy argument for which TKR rules should be ignored. If not specified, TKR rules are ignored for all dummy arguments in the procedure that contains the directive.

Rules

The following rules apply to this directive:

- IGNORE_TKR must not specify dummy arguments that are allocatable, Fortran 90 pointers, or assumed-shape arrays.
- IGNORE_TKR may only appear in the body of an interface block and may specify dummy argument names only.
- IGNORE_TKR may appear before or after the declarations of the dummy arguments it specifies.
- If dummy argument names are specified, IGNORE_TKR applies only to those particular dummy arguments.
- If no dummy argument names are specified, IGNORE_TKR applies to all dummy arguments except those that are allocatable objects, Fortran 90 pointers, or assumed-shape arrays.

Example:

Consider this subroutine fragment:

```
subroutine example(A,B,C,D)
!DIR$ IGNORE_TKR A, (R) B, (TK) C, (K) D
```

[Table 5.1](#) indicates which rules are ignored for which dummy arguments in the sample subroutine fragment:

Table 5.1. IGNORE_TKR Example

Dummy Argument	Ignored Rules
A	Type, Kind and Rank
B	Only rank
C	Type and Kind
D	Only Kind

Notice that no letters were specified for A, so all type, kind, and rank rules are ignored.

Chapter 6. Run-time Environment

This chapter describes the programming model supported for compiler code generation, including register conventions and calling conventions for x86 and x64 processor-based systems running a Windows operating system.

Note

In this chapter we sometimes refer to word, halfword, and double word. The equivalent byte information is word (4 byte), halfword (2 byte), and double word (8 byte).

Win32 Programming Model

This section defines compiler and assembly language conventions for the use of certain aspects of an x86 processor running a Win32 operating system. These standards must be followed to guarantee that compilers, application programs, and operating systems written by different people and organizations will work together. The conventions supported by the Fortran compiler implement the application binary interface (ABI) as defined in the System V Application Binary Interface: Intel Processor Supplement and the System V Application Binary Interface, listed in the "Related Publications" section in the Preface.

Function Calling Sequence

This section describes the standard function calling sequence, including the stack frame, register usage, and parameter passing.

Register Usage Conventions

The following table defines the standard for register allocation. The 32-bit x86 Architecture provides a number of registers. All the integer registers and all the floating-point registers are global to all procedures in a running program.

Table 6.1. Register Allocation

Type	Name	Purpose
General	%eax	integer return value
	%edx	dividend register (for divide operations)
	%ecx	count register (shift and string operations)
	%ebx	local register variable
	%ebp	optional stack frame pointer
	%esi	local register variable
	%edi	local register variable
	%esp	stack pointer
Floating-point	%st(0)	floating-point stack top, return value
	%st(1)	floating-point next to stack top
	%st(...)	
	%st(7)	floating-point stack bottom

In addition to the registers, each function has a frame on the run-time stack. This stack grows downward from high addresses. The next table shows the stack frame organization.

Table 6.2. Standard Stack Frame

Position	Contents	Frame
$4n+8$ (%ebp)	argument word n	previous
argument words 1 to $n-1$		
8 (%ebp)	argument word 0	
4 (%ebp)	return address	
0 (%ebp)	caller's %ebp	current
-4 (%ebp)	n bytes of local	
- n (%ebp)	variables and temps	

Key points concerning the stack frame include:

- The stack is kept double word aligned.
- Argument words are pushed onto the stack in reverse order so the rightmost argument in C call syntax has the highest address. A dummy word may be pushed ahead of the rightmost argument in order to preserve doubleword alignment. All incoming arguments appear on the stack, residing in the stack frame of the caller.
- An argument's size is increased, if necessary, to make it a multiple of words. This may require tail padding, depending on the size of the argument.

All registers on an x86 system are global and thus visible to both a calling and a called function. Registers %ebp, %ebx, %edi, %esi, and %esp are non-volatile across function calls. Therefore, a function must preserve these registers' values for its caller. Remaining registers are volatile (scratch). If a calling function wants to preserve such a register value across a function call, it must save its value explicitly.

Some registers have assigned roles in the standard calling sequence:

%esp

The stack pointer holds the limit of the current stack frame, which is the address of the stack's bottom-most, valid word. At all times, the stack pointer should point to a word-aligned area.

%ebp

The frame pointer holds a base address for the current stack frame. Consequently, a function has registers pointing to both ends of its frame. Incoming arguments reside in the previous frame, referenced as positive offsets from %ebp, while local variables reside in the current frame, referenced as negative offsets from %ebp. A function must preserve this register value for its caller.

%eax

Integral and pointer return values appear in %eax. A function that returns a structure or union value places the address of the result in %eax. Otherwise, this is a scratch register.

%esi, %edi

These local registers have no specified role in the standard calling sequence. Functions must preserve their values for the caller.

%ecx, %edx

Scratch registers have no specified role in the standard calling sequence. Functions do not have to preserve their values for the caller.

%st(0)

Floating-point return values appear on the top of the floating point register stack; there is no difference in the representation of single or double-precision values in floating point registers. If the function does not return a floating point value, then the stack must be empty.

%st(1) - %st(7)

Floating point scratch registers have no specified role in the standard calling sequence. These registers must be empty before entry and upon exit from a function.

EFLAGS

The flags register contains the system flags, such as the direction flag and the carry flag. The direction flag must be set to the "forward" (i.e., zero) direction before entry and upon exit from a function. Other user flags have no specified role in the standard calling sequence and are not reserved.

Floating Point Control Word

The control word contains the floating-point flags, such as the rounding mode and exception masking. This register is initialized at process initialization time and its value must be preserved.

Signals can interrupt processes. Functions called during signal handling have no unusual restriction on their use of registers. Moreover, if a signal handling function returns, the process resumes its original execution path with registers restored to their original values. Thus, programs and compilers may freely use all registers without danger of signal handlers changing their values.

Function Return Values

Functions Returning No Value

Functions that return no value are also called procedures or void functions. These functions put no particular value in any register.

Functions Returning Scalars

- A function that returns an integral or pointer value places its result in register `%eax`.
- A function that returns a long long integer value places its result in the registers `%edx` and `%eax`. The most significant word is placed in `%edx` and the least significant word is placed in `%eax`.
- A floating-point return value appears on the top of the floating point stack. The caller must then remove the value from the floating point stack, even if it does not use the value. Failure of either side to meet its obligations leads to undefined program behavior. The standard calling sequence does not include any method to detect such failures nor to detect return value type mismatches. Therefore, the user must declare all functions properly. There is no difference in the representation of single-, double- or extended-precision values in floating-point registers.
- A call instruction pushes the address of the next instruction (the return address) onto the stack. The return instruction pops the address off the stack and effectively continues execution at the next instruction after the call instruction. A function that returns a scalar or no value must preserve the caller's registers. Additionally, the called function must remove the return address from the stack, leaving the stack pointer (`%esp`) with the value it had before the call instruction was executed.

Functions Returning Structures or Unions

If a function returns a structure or union, then the caller provides space for the return value and places its address on the stack as argument word zero. In effect, this address becomes a hidden first argument.

A function that returns a structure or union also sets `%eax` to the value of the original address of the caller's area before it returns. Thus, when the caller receives control again, the address of the returned object resides in register `%eax` and can be used to access the object. Both the calling and the called functions must cooperate to pass the return value successfully:

- The calling function must supply space for the return value and pass its address in the stack frame;
- The called function must use the address from the frame and copy the return value to the object so supplied;
- The called function must remove this address from the stack before returning.

Failure of either side to meet its obligation leads to undefined program behavior. The standard function calling sequence does not include any method to detect such failures nor to detect structure and union type mismatches. Therefore, you must declare the function properly.

The following table illustrates the stack contents when the function receives control, after the call instruction, and when the calling function again receives control, after the `ret` instruction.

Table 6.3. Stack Contents for Functions Returning struct/union

Position	After Call	After Return	Position
4n+8 (%esp)	argument word n	argument word n	4n-4 (%esp)
8 (%esp)	argument word 1	argument word 1	0 (%esp)
4 (%esp)	value address	undefined	
0 (%esp)	return address		

The following sections of this chapter describe where arguments appear on the stack. The examples in this chapter are written as if the function prologue is used.

Argument Passing

Integral and Pointer Arguments

As mentioned, a function receives all its arguments through the stack; the last argument is pushed first. In the standard calling sequence, the first argument is at offset 8(%ebp), the second argument is at offset 12(%ebp), as previously shown in [Table 6.3, “Stack Contents for Functions Returning struct/union”](#). Functions pass all integer-valued arguments as words, expanding or padding signed or unsigned bytes and halfwords as needed.

Table 6.4. Integral and Pointer Arguments

Call	Argument	Stack Address
g(1, 2, 3, (void *)0);	1	8 (%ebp)
	2	12 (%ebp)
	3	16 (%ebp)
	(void *) 0	20 (%ebp)

Floating-Point Arguments

The stack also holds floating-point arguments: single-precision values use one word and double-precision use two. The following example uses only double-precision arguments.

Table 6.5. Floating-point Arguments

Call	Argument	Stack Address
h(1.414, 1, 2.998e10);	word 0, 1.414	8 (%ebp)
	word 1, 1.414	12 (%ebp)
	1	16 (%ebp)
	word 0 2.998e10	20 (%ebp)
	word 1, 2.998e10	24 (%ebp)

Structure and Union Arguments

Structures and unions can have byte, halfword, or word alignment, depending on the constituents. An argument's size is increased, if necessary, to make it a multiple of words. This size increase may require tail padding, depending on the size of the argument. Structure and union arguments are pushed onto the stack in the same manner as integral arguments. This process provides call-by-value semantics, letting the called function modify its arguments without affecting the calling function's object. In the following example, the argument, `s`, is a structure consisting of more than 2 words.

Table 6.6. Structure and Union Arguments

Call	Argument	Stack Address
<code>i(1,s);</code>	<code>1</code>	<code>8 (%ebp)</code>
	<code>word 0, s</code>	<code>12 (%ebp)</code>
	<code>word 1, s</code>	<code>16 (%ebp)</code>
	<code>...</code>	<code>...</code>

Implementing a Stack

In general, compilers and programmers must maintain a software stack. Register `%esp` is the stack pointer. Register `%esp` is set by the operating system for the application when the program is started. The stack must be a grow-down stack.

A separate frame pointer enables calls to routines that change the stack pointer to allocate space on the stack at run-time (e.g. `alloca`). Some languages can also return values from a routine allocated on stack space below the original top-of-stack pointer. Such a routine prevents the calling function from using `%esp`-relative addressing to get at values on the stack. If the compiler does not call routines that leave `%esp` in an altered state when they return, a frame pointer is not needed and is not used if the compiler option `-Mnoframe` is specified.

Although not required, the stack should be kept aligned on 8-byte boundaries so that 8-byte locals are favorably aligned with respect to performance. PGI's compilers allocate stack space for each routine in multiples of 8 bytes.

Variable Length Parameter Lists

Parameter passing in registers can handle a variable number of parameters. The C language uses a special method to access variable-count parameters. The `stdarg.h` and `varargs.h` files define several functions to access these parameters. A C routine with variable parameters must use the `va_start` macro to set up a data structure before the parameters can be used. The `va_arg` macro must be used to access the successive parameters.

C Parameter Conversion

In C, for a called prototyped function, the parameter type in the called function must match the argument type in the calling function. If the called function is not prototyped, the calling convention uses the types of the arguments but promotes char or short to int, and unsigned char or unsigned short to unsigned int and promotes float to double, unless you use the `-Msingle` option. For more information on the `-Msingle` option, refer to [Chapter 2, “*Command-Line Options Reference*”](#). If the called function is prototyped, the unused bits of a register containing a char or short parameter are undefined and the called function must extend the sign of the unused bits when needed.

Calling Assembly Language Programs

The following example shows a C program calling an assembly-language routine `sum_3`.

Example 6.1. C Program Calling an Assembly-language Routine

```
/* File: testmain.c */
main() {
    long l_para1 = 0x3f800000;
    float f_para2 = 1.0;
    double d_para3 = 0.5;
    float f_return;
    extern float sum_3 (long para1, float para2, double para3);
    f_return = sum_3(l_para1, f_para2, d_para3);
    printf("Parameter one, type long = %08x\n", l_para1);
    printf("Parameter two, type float = %f\n", f_para2);
    printf("Parameter three, type double = %g\n", d_para3);
    printf("The sum after conversion = %f\n", f_return);
}
```

```
# File: sum_3.s
# Computes ( para1 + para2 ) + para3
.text
.align 4
.long .EN1-sum_3+0xc8000000
.align 16
.globl sum_3
sum_3:
    pushl %ebp
    movl %esp, %ebp
    subl $8, %esp
..EN1:
    fildl 8(%ebp)
    fadds 12(%ebp)
    faddl 16(%ebp)
    fstps -4(%ebp)
    flds -4(%ebp)
    addl $8, %esp
    leave
    ret
.type sum_3,@function
.size sum_3,.-sum_3
```

Win64 Programming Model

This section defines compiler and assembly language conventions for the use of certain aspects of an x64 processor running a Win64 operating system. These standards must be followed to guarantee that compilers, application programs, and operating systems written by different people and organizations will work together. The conventions supported by the Fortran compiler implement the application binary interface (ABI) as defined in the AMD64 Software Conventions document.

Function Calling Sequence

This section describes the standard function calling sequence, including the stack frame, register usage, and parameter passing.

Register Usage Conventions

The following table defines the standard for register allocation. The 64-bit AMD64 and Intel 64 architectures provide a number of registers. All the general purpose registers, XMM registers, and x87 registers are global to all procedures in a running program.

Table 6.7. Register Allocation

Type	Name	Purpose
General	%rax	return value register
	%rbx	callee-saved
	%rcx	pass 1st argument to functions
	%rdx	pass 2nd argument to functions
	%rsp	stack pointer
	%rbp	callee-saved; optional stack frame pointer
	%rsi	callee-saved
	%rdi	callee-saved
	%r8	pass 3rd argument to functions
	%r9	pass 4th argument to functions
	%r10-%r11	temporary registers; used in syscall/sysret instructions
	%r12-r15	callee-saved registers
XMM	%xmm0	pass 1st floating point argument; return value register
	%xmm1	pass 2nd floating point argument
	%xmm2	pass 3rd floating point argument
	%xmm3	pass 4th floating point argument
	%xmm4-%xmm5	temporary registers
	%xmm6-%xmm15	callee-saved registers

In addition to the registers, each function has a frame on the run-time stack. This stack grows downward from high addresses. [Table 6.8](#) shows the stack frame organization.

Table 6.8. Standard Stack Frame

Position	Contents	Frame
8n-120 (%rbp)	argument eightbyte n	previous
	...	
-80 (%rbp)	argument eightbyte 5	
-88 (%rbp)	%r9 home	
-96 (%rbp)	%r8 home	
-104 (%rbp)	%rdx home	
-112 (%rbp)	%rcx home	
-120 (%rbp)	return address	current
-128 (%rbp)	caller's %rbp	
	...	
0 (%rsp)	variable size	

Key points concerning the stack frame:

- The parameter area at the bottom of the stack must contain enough space to hold all the parameters needed by any function call. Space must be set aside for the four register parameters to be "homed" to the stack even if there are less than four register parameters used in a given call.
- Sixteen-byte alignment of the stack is required except within a function's prolog and within leaf functions.

All registers on an x64 system are global and thus visible to both a calling and a called function. Registers %rbx, %rsp, %rbp, %rsi, %rdi, %r12, %r13, %r14, and %r15 are non-volatile. Therefore, a called function must preserve these registers' values for its caller. Remaining registers are scratch. If a calling function wants to preserve such a register value across a function call, it must save a value in its local stack frame.

Registers are used in the standard calling sequence. The first four arguments are passed in registers. Integral and pointer arguments are passed in these general purpose registers (listed in order): %rcx, %rdx, %r8, %r9. Floating point arguments are passed in the first four XMM registers: %xmm0, %xmm1, %xmm2, %xmm3. Registers are assigned using the argument's ordinal position in the argument list. For example, if a function's first argument is an integral type and its second argument is a floating-point type, the first argument will be passed in the first general purpose register (%rcx) and the second argument will be passed in the second XMM register (%xmm1); the first XMM register and second general purpose register are ignored. Arguments after the first four are passed on the stack.

Integral and pointer type return values are returned in %rax. Floating point return values are returned in %xmm0.

Additional registers with assigned roles in the standard calling sequence:

%rsp

The stack pointer holds the limit of the current stack frame, which is the address of the stack's bottom-most, valid word. The stack pointer should point to a 16-byte aligned area unless in the prolog or a leaf function.

%rbp

The frame pointer, if used, can provide a way to reference the previous frames on the stack. Details are implementation dependent. A function must preserve this register value for its caller.

MXCSR

The flags register MXCSR contains the system flags, such as the direction flag and the carry flag. The six status flags (MXCSR[0:5]) are volatile; the remainder of the register is nonvolatile.

x87 - Floating Point Control Word (FPCSR)

The control word contains the floating-point flags, such as the rounding mode and exception masking. This register is initialized at process initialization time and its value must be preserved.

Signals can interrupt processes. Functions called during signal handling have no unusual restriction on their use of registers. Moreover, if a signal handling function returns, the process resumes its original execution path with registers restored to their original values. Thus, programs and compilers may freely use all registers without danger of signal handlers changing their values.

Function Return Values

Functions Returning Scalars or No Value

- A function that returns an integral or pointer value that fits in 64 bits places its result in %rax.
- A function that returns a floating point value that fits in the XMM registers returns this value in %xmm0.
- A function that returns a value in memory via the stack places the address of this memory (passed to the function as a "hidden" first argument in %rcx) in %rax.
- Functions that return no value (also called procedures or void functions) put no particular value in any register.
- A call instruction pushes the address of the next instruction (the return address) onto the stack. The return instruction pops the address off the stack and effectively continues execution at the next instruction after the call instruction. A function that returns a scalar or no value must preserve the caller's registers as previously described. Further, the called function must remove the return address from the stack, leaving the stack pointer (%rsp) with the value it had before the call instruction was executed.

Functions Returning Structures or Unions

A function can use either registers or the stack to return a structure or union. The size and type of the structure or union determine how it is returned. A structure or union is returned in memory if it is larger than 8 bytes or if its size is 3, 5, 6, or 7 bytes. A structure or union is returned in %rax if its size is 1, 2, 4, or 8 bytes.

If a structure or union is to be returned in memory, the caller provides space for the return value and passes its address to the function as a "hidden" first argument in %rcx. This address will also be returned in %rax.

Argument Passing

Integral and Pointer Arguments

Integral and pointer arguments are passed to a function using the next available register of the sequence `%rcx`, `%rdx`, `%r8`, `%r9`. After this list of registers has been exhausted, all remaining integral and pointer arguments are passed to the function via the stack.

Floating-Point Arguments

Float and double arguments are passed to a function using the next available XMM register of the sequence `%xmm0`, `%xmm1`, `%xmm2`, `%xmm3`. After this list of registers has been exhausted, all remaining XMM floating-point arguments are passed to the function via the stack.

Array, Structure, and Union Arguments

Arrays and strings are passed to functions using a pointer to caller-allocated memory.

Structure and union arguments of size 1, 2, 4, or 8 bytes will be passed as if they were integers of the same size. Structures and unions of other sizes will be passed as a pointer to a temporary, allocated by the caller, and whose value contains the value of the argument. The caller-allocated temporary memory used for arguments of aggregate type must be 16-byte aligned.

Passing Arguments on the Stack

Registers are assigned using the argument's ordinal position in the argument list. For example, if a function's first argument is an integral type and its second argument is a floating-point type, the first argument will be passed in the first general purpose register (`%rcx`) and the second argument will be passed in the second XMM register (`%xmm1`); the first XMM register and second general purpose register are ignored. Arguments after the first four are passed on the stack; they are pushed on the stack in reverse order, with the last argument pushed first.

[Table 6.9, “Register Allocation for Example A-4”](#) shows the register allocation and stack frame offsets for the function declaration and call shown in the following example.

Example 6.2. Parameter Passing

```
typedef struct {
    int i;
    float f;
} struct1;
int i;
float f;
double d;
long l;
long long ll;
struct1 s1;
extern void func (int i, float f, struct1 s1, double d, long long ll, long l);
func (i, f, s1, d, ll, l);
```

Table 6.9. Register Allocation for Example A-4

General Purpose Registers	Floating Point Registers	Stack Frame Offset
%rcx: i	%xmm0: <ignored>	32: ll
%rdx: <ignored>	%xmm1: f	40: l
%r8: s1.i, s1.f	%xmm2: <ignored>	
%r9: <ignored>	%xmm3: d	

Implementing a Stack

In general, compilers and programmers must maintain a software stack. The stack pointer, register `%rsp`, is set by the operating system for the application when the program is started. The stack must grow downwards from high addresses.

A separate frame pointer enables calls to routines that change the stack pointer to allocate space on the stack at run-time (e.g. `alloca`). Some languages can also return values from a routine allocated on stack space below the original top-of-stack pointer. Such a routine prevents the calling function from using `%rsp`-relative addressing to get at values on the stack. If the compiler does not call routines that leave `%rsp` in an altered state when they return, a frame pointer is not needed and is not used if the compiler option `-Mnoframe` is specified.

The stack must always be 16-byte aligned except within the prolog and within leaf functions.

Variable Length Parameter Lists

Parameter passing in registers can handle a variable number of parameters. The C language uses a special method to access variable-count parameters. The `stdarg.h` and `varargs.h` files define several functions to access these parameters. A C routine with variable parameters must use the `va_start` macro to set up a data structure before the parameters can be used. The `va_arg` macro must be used to access the successive parameters.

For unprototyped functions or functions that use `varargs`, floating-point arguments passed in registers must be passed in both an XMM register and its corresponding general purpose register.

C Parameter Conversion

In C, for a called prototyped function, the parameter type in the called function must match the argument type in the calling function.

- If the called function is not prototyped, the calling convention uses the types of the arguments but promotes `char` or `short` to `int`, and unsigned `char` or unsigned `short` to unsigned `int` and promotes `float` to `double`, unless you use the `-Msingle` option.

For more information on the `-Msingle` option, refer to [Chapter 2, “Command-Line Options Reference”](#).

- If the called function is prototyped, the unused bits of a register containing a `char` or `short` parameter are undefined and the called function must extend the sign of the unused bits when needed.

Calling Assembly Language Programs

Example 6.3. C Program Calling an Assembly-language Routine

```

/* File: testmain.c */
main() {
    long l_para1 = 0x3f800000;
    float f_para2 = 1.0;
    double d_para3 = 0.5;
    float f_return;
    extern float sum_3 (long para1, float para2, double para3);
    f_return = sum_3(l_para1, f_para2, d_para3);
    printf("Parameter one, type long = %08x\n", l_para1);
    printf("Parameter two, type float = %f\n", f_para2);
    printf("Parameter three, type double = %g\n", d_para3);
    printf("The sum after conversion = %f\n", f_return);
}
# File: sum_3.s
# Computes ( para1 + para2 ) + para3
.text
.align 16
.globl sum_3
sum_3:
    pushq %rbp
    leaq 128(%rsp), %rbp
    cvtsi2ss %ecx, %xmm0
    addss %xmm1, %xmm0
    cvtss2sd %xmm0, %xmm0
    addsd %xmm2, %xmm0
    cvtsd2ss %xmm0, %xmm0

    ret
.type sum_3,@function
.size sum_3,.-sum_3

```

Win64 Fortran Supplement

Sections A3.4.1 through A3.4.4 of the AMD64 Software Conventions for Win64 define the Fortran supplement. The register usage conventions set forth in that document remain the same for Fortran.

Fortran Fundamental Types

Table 6.10. Win64 Fortran Fundamental Types

Fortran Type	Size (bytes)	Alignment (bytes)
INTEGER	4	4
INTEGER*1	1	1
INTEGER*2	2	2
INTEGER*4	4	4
INTEGER*8	8	8
LOGICAL	4	4

Fortran Type	Size (bytes)	Alignment (bytes)
LOGICAL*1	1	1
LOGICAL*2	2	2
LOGICAL*4	4	4
LOGICAL*8	8	8
BYTE	1	1
CHARACTER*n	n	1
REAL	4	4
REAL*4	4	4
REAL*8	8	8
DOUBLE PRECISION	8	8
COMPLEX	8	4
COMPLEX*8	8	4
COMPLEX*16	16	8
DOUBLE COMPLEX	16	8

A logical constant is one of:

- `.TRUE.`
- `.FALSE.`

The logical constants `.TRUE.` and `.FALSE.` are defined to be the four-byte value 1 and 0 respectively. A logical expression is defined to be `.TRUE.` if its least significant bit is 1 and `.FALSE.` otherwise.

Note that the value of a character is not automatically NULL-terminated.

Fortran Naming Conventions

By default, all globally visible Fortran symbol names (subroutines, functions, common blocks) are converted to lower-case. In addition, an underscore is appended to Fortran global names to distinguish the Fortran name space from the C/C++ name space.

Fortran Argument Passing and Return Conventions

Arguments are passed by reference, meaning the address of the argument is passed rather than the argument itself. In contrast, C/C++ arguments are passed by value.

When passing an argument declared as Fortran type `CHARACTER`, an argument representing the length of the `CHARACTER` argument is also passed to the function. This length argument is a four-byte integer passed by value, and is passed at the end of the parameter list following the other formal arguments. A length argument is

passed for each CHARACTER argument; the length arguments are passed in the same order as their respective CHARACTER arguments.

A Fortran function, returning a value of type CHARACTER, adds two arguments to the beginning of its argument list. The first additional argument is the address of the area created by the caller for the return value; the second additional argument is the length of the return value. If a Fortran function is declared to return a character value of constant length, for example `CHARACTER*4 FUNCTION CHF()`, the second extra parameter representing the length of the return value must still be supplied.

A Fortran complex function returns its value in memory. The caller provides space for the return value and passes the address of this storage as if it were the first argument to the function.

Alternate return specifiers of a Fortran function are not passed as arguments by the caller. The alternate return function passes the appropriate return value back to the caller in %rax.

The handling of the following Fortran 90 features is implementation-defined: internal procedures, pointer arguments, assumed-shape arguments, functions returning arrays, and functions returning derived types.

Inter-language Calling

Inter-language calling between Fortran and C/C++ is possible if function/subroutine parameters and return values match types. If a C/C++ function returns a value, call it from Fortran as a function, otherwise, call it as a subroutine. If a Fortran function has type CHARACTER or COMPLEX, call it from C/C++ as a void function. If a Fortran subroutine has alternate returns, call it from C/C++ as a function returning int; the value of such a subroutine is the value of the integer expression specified in the alternate RETURN statement. If a Fortran subroutine does not contain alternate returns, call it from C/C++ as a void function.

Table 6.11 provides the C/C++ data type corresponding to each Fortran data type.

Table 6.11. Fortran and C/C++ Data Type Compatibility

Fortran Type	C/C++ Type	Size (bytes)
CHARACTER*n x	char x[n]	n
REAL x	float x	4
REAL*4 x	float x	4
REAL*8 x	double x	8
DOUBLE PRECISION x	double x	8
INTEGER x	int x	4
INTEGER*1 x	signed char x	1
INTEGER*2 x	short x	2
INTEGER*4 x	int x	4
INTEGER*8 x	long long x	8
LOGICAL x	int x	4
LOGICAL*1 x	char x	1
LOGICAL*2 x	short x	2

Fortran Type	C/C++ Type	Size (bytes)
LOGICAL*4 x	int x	4
LOGICAL*8 x	long long x	8

The PGI Compiler User's Guide contains a table that provides the Fortran and C/C++ representation of the COMPLEX type.

Table 6.12. Fortran and C/C++ Representation of the COMPLEX Type

Fortran Type (lower case)	C/C++ Type	Size (bytes)
complex x	struct {float r,i;} x;	8
	float complex x;	8
complex*8 x	struct {float r,i;} x;	8
	float complex x;	8
double complex x	struct {double dr,di;} x;	16
	double complex x;	16
complex *16 x	struct {double dr,di;} x;	16
	double complex x;	16

Note

For C/C++, the `complex` type implies C99 or later.

Arrays

For a number of reasons inter-language function mixing is not recommended for arrays other than single dimensional arrays and square two-dimensional arrays.

- C/C++ arrays and Fortran arrays use different default initial array index values. By default, C/C++ arrays start at 0 and Fortran arrays start at 1. However, a Fortran array can be declared to start at zero.
- Fortran and C/C++ arrays use different storage methods. Fortran uses column-major order and C/C++ use row-major order. For one-dimensional arrays, this poses no problems. For two-dimensional arrays, where there are an equal number of rows and columns, row and column indexes can simply be reversed.

Structures, Unions, Maps, and Derived Types.

Fields within Fortran structures and derived types, and multiple map declarations within a Fortran union, conform to the same alignment requirements used by C structures.

Common Blocks

A named Fortran common block can be represented in C/C++ by a structure whose members correspond to the members of the common block. The name of the structure in C/C++ must have the added underscore. Here is an example.

Fortran common block:

```

INTEGER I, J
COMPLEX C
DOUBLE COMPLEX CD
DOUBLE PRECISION D
COMMON /COM/ i, j, c, cd, d

```

C equivalent:

```

extern struct {
  int i;
  int j;
  struct {float real, imag;} c;
  struct {double real, imag;} cd;
  double d;
} com_;

```

C++ equivalent:

```

extern "C" struct {
  int i;
  int j;
  struct {float real, imag;} c;
  struct {double real, imag;} cd;
  double d;
} com_;

```

Note

The compiler-provided name of the BLANK COMMON block is implementation-specific.

Calling Fortran COMPLEX and CHARACTER functions from C/C++ is not as straightforward as calling other types of Fortran functions. Additional arguments must be passed to the Fortran function by the C/C++ caller. A Fortran COMPLEX function returns its value in memory; the first argument passed to the function must contain the address of the storage for this value. A Fortran CHARACTER function adds two arguments to the beginning of its argument list. The following example of calling a Fortran CHARACTER function from C/C++ illustrates these caller-provided extra parameters:

```

CHARACTER*(*) FUNCTION CHF(C1, I)
CHARACTER*(*) C1
INTEGER I
END

```

```

extern void chf_();
char tmp[10];
char c1[9];
int i;
chf_(tmp, 10, c1, &i, 9);

```

The extra parameters `tmp` and `10` are supplied for the return value, while `9` is supplied as the length of `c1`.

Chapter 7. PVF Properties

There are a number of property pages that are available in a PVF project. These property pages are grouped into categories that you can access from the Property Page dialog. Further, each of PVF's property pages contains one or more properties, or configuration options. The set of categories and property pages available vary, depending on the type of project.

The properties in a PVF project are divided into the following categories:

- General
- Debugging
- Fortran
- Linker
- Librarian
- Resources
- Build Events
- Custom Build Step

This chapter contains descriptions of each of PVF's property pages. The summary table, [Table 7.1](#), lists the properties in alphabetical order for quick reference.

The remainder of this chapter provides detailed descriptions of the properties, organized as you would see them in the Property Page dialog: by category and property page.

Tip

The Fortran, Linker, and Librarian categories contain a Command Line property page where you can see the command line derived from the properties in that category. Options that are not supported by the PVF property pages can be added to the command line from this property page by entering them in the *Additional Options* field.

Property Page Summary

Table 7.1 lists the properties in alphabetical order for quick reference. Whenever applicable, the description shows the command line option associated with the property.

Table 7.1. PVF Property Page Summary

Use this Property...	From this Property Page...	To do this...
Accelerator Information	Fortran Diagnostics	Generate information about accelerator regions. (-Minfo=accel)
Additional Arguments: job submit	Debugging [Cluster MPI]	Specify additional arguments to be passed to the <code>job submit</code> command.
Additional Arguments: mpiexec	Debugging [Cluster MPI]	Specify additional arguments to be passed to <code>mpiexec</code> .
Additional Arguments: mpiexec	Debugging [Local MPI]	Specify additional arguments to be passed to <code>mpiexec</code> .
Additional Dependencies	Custom Build Step General	Specify additional input files to use as dependencies.
Additional Dependencies	Librarian General	Specify one or more directories to the library search path.
Additional Dependencies	Linker Input	Specify additional dependencies, such as libraries, to the link line.
Additional Include Directories	Fortran General	Specify one or more directories to add to the compiler's include path.
Additional Include Directories	Fortran Preprocessing	Specify one or more directories to add to the compiler's include path.
Additional Library Directories	Librarian General	Specify one or more directories to add to the library search path.
Additional Library Directories	Linker General	Specify one or more directories to add to the library search path.
AMD Athlon	Fortran Target Processors	Optimize for AMD Athlon, AMD Opteron and compatible processors. (-tp=k8-32) (-tp=k8-64)
AMD Barcelona	Fortran Target Processors	Optimize for AMD Opteron/Quadcore and compatible processors. (-tp=barcelona-32) (-tp=barcelona-64)

Use this Property...	From this Property Page...	To do this...
AMD Bulldozer	Fortran Target Processors	Optimize for AMD Bulldozer and compatible processors. (-tp=bulldozer-32) (-tp=bulldozer-64)
AMD Istanbul	Fortran Target Processors	Optimize for AMD Istanbul processor-based systems. (-tp=istanbul-32) (-tp=istanbul-64)
AMD Shanghai	Fortran Target Processors	Optimize for AMD Shanghai processor-based systems. (-tp=shanghai-32) (-tp=shanghai-64)
Annotate Assembly	Fortran Diagnostics	Generate an assembly file (.s) that is annotated with source code. (-Manno)
Application Arguments	Debugging [All]	Pass command line arguments to the application when it is run or debugged.
Application Command	Debugging [All]	Specify the application to execute when you select <i>Start Debugging</i> or <i>Start Without Debugging</i> from the <i>Debug</i> menu.
Auto-Parallelization	Fortran Optimization	Enable auto-parallelization of parallelizable code. (-Mconcur)
Build Log File	General	Specify the build log file that is produced when the project is built.
Build Log Level	General	Specify the level of detail to be included in the build log file.
Calling Convention	Fortran External Procedures	Specify an alternate calling convention. Default: Accept the default calling convention. C By Reference: Use the CREF calling conventions. (-Miface=cref) Unix: [Win32 platform only] Use the UNIX calling convention. (-Miface=unix)
Case of External Names	Fortran External Procedures	Specify the case used for Fortran external names. (-Mnames)

Use this Property...	From this Property Page...	To do this...
CCFF Information	Fortran Diagnostics	Append common compiler feedback format information to object files. (-Minfo=ccff)
Check Array Bounds	Fortran Runtime	Enable array bounds checking at runtime. (-Mbounds)
Check Pointers	Fortran Runtime	Perform runtime checks for pointers that are dereferenced while initialized to null. (-Mchkptr)
Check Stack	Fortran Runtime	Perform runtime stack checks for available space in the prologue of a function and before the start of a parallel region. (-Mchkstk)
Command Line	Build Events Pre-Build	Specify the command line that the build tool will run.
Command Line	Build Events Pre-Link	Specify the command line that the build tool will run.
Command Line	Build Events Post-Build	Specify the command line that the build tool will run.
Command Line	Custom Build Step General	Specify the command line that the build tool will run.
Command Line	Fortran Command Line	Specify options that you want used during compilation but that are not available through any of the Fortran property pages.
Command Line	Librarian Command Line	Specify options to use at link time that are not available from the Librarian property pages.
Command Line	Linker Command Line	Specify options to use at link time that are not available from the Linker property pages.
Command Line	Resources Command Line	Add options to the Resource compiler's command line.
Configuration Type	General	Change the output type that the project produces.
CUDA Fortran Compute Capability	Fortran Language	Either automatically generate code compatible with all applicable compute capabilities or use a manually selected set. (-Mcuda=cc10 cc11 cc12 cc13) cc20 cc30)

Use this Property...	From this Property Page...	To do this...
CUDA Fortran CC 1.0	Fortran Language	When Enable CUDA Fortran is set to Yes and CUDA Fortran Compute Capability is set to Manual : Yes: Enables generating code for compute capability 1.0 (-Mcuda=cc10) No: Disables generating code for compute capability 1.0
CUDA Fortran CC 1.1	Fortran Language	When Enable CUDA Fortran is set to Yes and CUDA Fortran Compute Capability is set to Manual : Yes: Enables generating code for compute capability 1.1 (-Mcuda=cc11) No: Disables generating code for compute capability 1.1
CUDA Fortran CC 1.2	Fortran Language	When Enable CUDA Fortran is set to Yes and CUDA Fortran Compute Capability is set to Manual : Yes: Enables generating code for compute capability 1.2 (-Mcuda=cc12) No: Disables generating code for compute capability 1.2
CUDA Fortran CC 1.3	Fortran Language	When Enable CUDA Fortran is set to Yes and CUDA Fortran Compute Capability is set to Manual : Yes: Enables generating code for compute capability 1.3 (-Mcuda=cc13) No: Disables generating code for compute capability 1.3
CUDA Fortran CC 2.0	Fortran Language	When Enable CUDA Fortran is set to Yes and CUDA Fortran Compute Capability is set to Manual : Yes: Enables generating code for compute capability 2.0 (-Mcuda=cc20) No: Disables generating code for compute capability 2.0

Use this Property...	From this Property Page...	To do this...
CUDA Fortran CC 3.0	Fortran Language	When Enable CUDA Fortran is set to Yes and CUDA Fortran Compute Capability is set to Manual : Yes: Enables generating code for compute capability 3.0 (-Mcuda=cc30) No: Disables generating code for compute capability 3.0
CUDA Fortran Emulation	Fortran Language	Enable CUDA Fortran emulation mode. (-Mcuda=emu)
CUDA Fortran Flush to Zero	Fortran Language	When Enable CUDA Fortran is set to Yes , controls flush-to-zero mode for floating point computations in the GPU code generated for CUDA Fortran kernels. Default: Accepts the default handling of floating point computations in the GPU code generated for CUDA Fortran kernels. Yes: Enables flush-to-zero mode (-Mcuda=flushz) No: Disables flush-to-zero mode (-Mcuda=noflushz)
CUDA Fortran Keep Binary	Fortran Language	Keep the Cuda binary (.bin) file. (-Mcuda=keepbin).
CUDA Fortran Keep Kernel Source	Fortran Language	Keep the kernel source files. (-Mcuda=keepgpu).
CUDA Fortran Keep PTX	Fortran Language	Keep the portable assembly (.ptx) file for the GPU code. (-Mcuda=keepptx.)
CUDA Fortran Keep PTXAS	Fortran Language	Show PTXAS informational messages during compilation. (-Mcuda=ptxinfo).
CUDA Fortran Register Limit	Fortran Language	Specify the maximum number of registers to use on the GPU. Leave blank for no limit. (-Mcuda=maxregcount:n)

Use this Property...	From this Property Page...	To do this...
CUDA Fortran Toolkit	Fortran Language	When Enable CUDA Fortran is set to <code>Yes</code> , specifies the version of the Cuda toolkit targeted by the compilers. Default: The compiler selects the default CUDA toolkit version. 2.3: Specifies use of toolkit version 2.3. 3.0: Specifies use of toolkit version 3.0. 3.1: Specifies use of toolkit version 3.1. 3.2: Specifies use of toolkit version 3.2. 4.0: Specifies use of toolkit version 4.0. 4.1: Specifies use of toolkit version 4.1. 4.2: Specifies use of toolkit version 4.2. (<code>-ta=nvidia:cuda2.3 cuda3.0 cuda3.1 cuda3.2 cuda4.0 cuda4.1 cuda4.2</code>)
CUDA Fortran Use Fast Math Library	Fortran Language	Use routines from the fast math library. (<code>-Mcuda=fastmath</code>)
CUDA Fortran Use Fused Multiply-Adds	Fortran Language	Control generation of fused multiply-add (FMA) instructions. <code>Yes</code> : Enables generation of FMA. (default) <code>No</code> : Disables generation of FMA. (<code>-Mcuda=nofma</code>)
Debug Information Format	Fortran General	Specify whether the compiler should generate debug information; and if so, in what format. (<code>-g</code>) (<code>-gopt</code>)
Description	Build Events Pre-Build	Echo the contents of the Description property to the Output window when this event is fired.
Description	Build Events Pre-Link	Echo the contents of the Description property to the Output window when this event is fired.
Description	Build Events Post-Build	Echo the contents of the Description property to the Output window when this event is fired.
Description	Custom Build Step General	Echo the contents of the Description property to the Output window when this event is fired.

Use this Property...	From this Property Page...	To do this...
Display Startup Banner	Fortran General	Add the <code>-v</code> switch to the compilation line so the compiler's startup banner is displayed during compilation.
Enable CUDA Fortran	Fortran Language	Enable CUDA Fortran. (<code>-Mcuda</code>)
Enable Limited DWARF	Fortran Profiling	Generate limited DWARF information to use with performance profilers. (<code>-Mprof=dwarf</code>).
Environment	Debugging [All]	Specify environment variables to set for the application when it runs.
Excluded From Build	Build Events Pre-Build	Specify whether this build event should be excluded from the build for the current configuration.
Excluded From Build	Build Events Pre-Link	Specify whether this build event should be excluded from the build for the current configuration.
Excluded From Build	Build Events Post-Build	Specify whether this build event should be excluded from the build for the current configuration.
Export Symbols	Linker General	Specify whether a DLL will export symbols.
Extend Line Length	Fortran Language	Extend the line length for fixed-format Fortran files to 132 characters. (<code>-Mextend</code>)
Extensions to Delete on Clean	General	Specify which files in the intermediate directory should be deleted when the project is cleaned or before it is rebuilt.
Floating Point Consistency	Fortran Floating Point Options	Enable relaxed floating point accuracy in favor of speed. (<code>-Mfprelaxed</code>)
Floating Point Exception Handling	Fortran Floating Point Options	Enable floating point exceptions through the compiler option: (<code>-Ktrap=fp</code>)
Flush Denormalized Results to Zero	Fortran Floating Point Options	Accept the default handling of denormalized floating point results. Yes: Enable SSE flush-to-zero mode. (<code>-Mflushz</code>) No: Disable SSE flush-to-zero mode. (<code>-Mnoflushz</code>)

Use this Property...	From this Property Page...	To do this...
Fortran Dialect	Fortran Language	Specify the Fortran language dialect to use during compilation.
Fortran Language Information	Fortran Diagnostics	Generate information about Fortran language features. (-Minfo=ftn)
Function-Level Profiling	Fortran Profiling	Generate code instrumented for function-level profiling. (-Mprof=func)
Generate Assembly	Fortran Diagnostics	Generate an assembly file (.s) during compilation. (-Mkeepasm)
Generic x86 [Win32 only]	Fortran Target Processors	Optimize for any x86 processor-based system. (-tp=px-32)
Generic x86-64 [x64 only]	Fortran Target Processors	Optimize for any x86-64 processor-based system. (-tp=px-64)
Global Optimizations	Fortran Optimization	Set the compiler's global optimization level by selecting a -O<level> option.
IEEE Arithmetic	Fortran Floating Point Options	Default: Accept the default floating point arithmetic. Yes: Enable IEEE floating point arithmetic: (-Kieee). No: Disable IEEE floating point arithmetic: (-Knoieee).
Ignore Standard Include Path	Fortran Preprocessing	Specify whether the preprocessor should ignore the standard include path. (-Mnostdinc).
Inlining	Fortran Optimization	Enable inlining for certain subprograms. (-Minline).
Inlining Information	Fortran Diagnostics	Generate information about inlining. (-Minfo=inline)
Intel Core 2	Fortran Target Processors	Optimize for Intel Core 2 Duo and compatible processors. (-tp=core2-32) (-tp=core2-64)

Use this Property...	From this Property Page...	To do this...
Intel Core i7	Fortran Target Processors	Optimize for Intel Core i7 processor-based systems. (-tp=nehalem-32) (-tp=nehalem-64)
Intel Penryn	Fortran Target Processors	Optimize for Intel Penryn architecture and compatible processors. (-tp=penryn-32) (-tp=penryn-64)
Intel Pentium 4	Fortran Target Processors	Optimize for Intel Pentium 4 and compatible processors. (-tp=p7-32) (-tp=p7-64)
Intel Sandy Bridge	Fortran Target Processors	Optimize for Intel Sandy Bridge and compatible processors. (-tp=sandybridge-32) (-tp=sandybridge-64)
Intermediate Directory	General	Specify a relative path to the intermediate file directory where the intermediate files (i.e., object files) are created when the project is built.
IPA Information	Fortran Diagnostics	Generate information about inter-procedural analysis optimizations. (-Minfo=ipa)
Line-Level Profiling	Fortran Profiling	Generate code instrumented for line-level profiling. (-Mprof=lines).
Location of job.exe	Debugging [Cluster MPI]	Override the default path to <code>job.exe</code> as specified in the system <code>PATH</code> variable.
Location of mpiexec	Debugging [Local MPI]	Override the default path to <code>mpiexec</code> as specified in the system <code>PATH</code> variable.
Loop Intensity Information	Fortran Diagnostics	Generate compute intensity information about loops. (-Minfo=intensity)
Loop Optimization Information	Fortran Diagnostics	Generate information about loop optimizations. (-Minfo=loop)
Loop Unroll Count	Fortran Optimization	Specify unrolling by two or four. (-Munroll)

Use this Property...	From this Property Page...	To do this...
LRE Information	Fortran Diagnostics	Generate information about loop-carried redundancy elimination. (-Minfo=lre)
Merge Environment	Debugging	Specify whether or not to merge the environment variables in the Environment property with the existing environment when the application is run or debugged.
Module Path	Fortran General	Specify the location of module (.mod) files.
MPI	Fortran Language	Specify whether or not to enable compiling and linking with the Microsoft MPI libraries.
MPI	Fortran Profiling	Specify whether to access profiled MPI communication libraries. Must be used in conjunction with function-level or line-level profiling.
MPI Debugging	Debugging [All]	Specify the run and debug mode: Disabled: In serial mode. Local: Using MPI locally. Cluster: Using MPI on a cluster.
NVIDIA: Analysis Only	Fortran Target Accelerators	Perform loop analysis only. Do not generate GPU code. (-ta=nvidia:analysis)
NVIDIA: Compute Capability	Fortran Target Accelerators	Generate code for the specified compute capability. (-ta=nvidia:cc10 cc11 cc12 cc13 cc20 cc30)
NVIDIA: CC 1.0	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes and NVIDIA Compute Capability is set to Manual: Yes: Enables generating code for compute capability 1.0 (-ta=nvidia:cc10) No: Disables generating code for compute capability 1.0

Use this Property...	From this Property Page...	To do this...
NVIDIA: CC 1.1	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes and NVIDIA Compute Capability is set to Manual: Yes: Enables generating code for compute capability 1.1 (-ta=nvidia:cc11) No: Disables generating code for compute capability 1.1
NVIDIA: CC 1.2	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes and NVIDIA Compute Capability is set to Manual: Yes: Enables generating code for compute capability 1.2 (-ta=nvidia:cc12) No: Disables generating code for compute capability 1.2
NVIDIA: CC 1.3	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes and NVIDIA Compute Capability is set to Manual: Yes: Enables generating code for compute capability 1.3 (-ta=nvidia:cc13) No: Disables generating code for compute capability 1.3
NVIDIA: CC 2.0	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes and NVIDIA Compute Capability is set to Manual: Yes: Enables generating code for compute capability 2.0 (-ta=nvidia:cc20) No: Disables generating code for compute capability 2.0
NVIDIA: CC 3.0	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes and NVIDIA Compute Capability is set to Manual: Yes: Enables generating code for compute capability 2.0 (-ta=nvidia:cc30) No: Disables generating code for compute capability 3.0

Use this Property...	From this Property Page...	To do this...
NVIDIA: CUDA Toolkit	Fortran Target Accelerators	<p>When Target NVIDIA Accelerator is set to Yes, specifies the CUDA toolkit version that is targeted by the compilers.</p> <p>Default: The compiler selects the default CUDA toolkit version.</p> <p>2 . 3: Specifies use of toolkit version 2.3.</p> <p>3 . 0: Specifies use of toolkit version 3.0.</p> <p>3 . 1: Specifies use of toolkit version 3.1.</p> <p>3 . 2: Specifies use of toolkit version 3.2.</p> <p>4 . 0: Specifies use of toolkit version 4.0.</p> <p>4 . 1: Specifies use of toolkit version 4.1.</p> <p>4 . 2: Specifies use of toolkit version 4.2.</p> <p>(-ta=nvidia:cuda2.3 cuda3.0 cuda3.1 cuda3.2 cuda4.0 cuda4.1 cuda4.2)</p>
NVIDIA: Enable Profiling	Fortran Target Accelerators	<p>Collect simple timing information for accelerator kernel profiling.</p> <p>(-ta=nvidia:time)</p>
NVIDIA: Flush to Zero	Fortran Target Accelerators	<p>When Target NVIDIA Accelerator is set to Yes, controls flush-to-zero mode for floating point computations in the GPU code generated for CUDA Fortran kernels.</p> <p>Default: Accepts the default handling of floating point computations in the GPU code generated for CUDA Fortran kernels.</p> <p>Yes: Enables flush-to-zero mode</p> <p>(-ta=nvidia:flushz)</p> <p>No: Disables flush-to-zero mode</p> <p>(-ta=nvidia:noflushz)</p>
NVIDIA: Keep Kernel Binary	Fortran Target Accelerators	<p>Keep kernel binary (.bin) files.</p> <p>(-ta=nvidia:keepbin)</p>
NVIDIA: Keep Kernel PTX	Fortran Target Accelerators	<p>Keep the portable assembly (.ptx) file for the GPU code.</p> <p>(-ta=nvidia:keepptx)</p>
NVIDIA: Keep Kernel Source	Fortran Target Accelerators	<p>Keep kernel source files.</p> <p>(-ta=nvidia:keepgpu)</p>
NVIDIA: Register Limit	Fortran Target Accelerators	<p>Specify the maximum number of registers to use on the GPU.</p> <p>Leave blank for no limit.</p> <p>(-ta=nvidia:maxregcount:n)</p>

Use this Property...	From this Property Page...	To do this...
NVIDIA: Synchronous Kernel Launch	Fortran Target Accelerators	When Target NVIDIA Accelerator is set to Yes, use this property to wait for each kernel to finish before continuing in the host program. Yes: wait for kernel to finish. This is the default. No: do not wait for kernel to finish. (-ta=nvidia:[no]wait)
NVIDIA: Use 24-bit Subscript Multiplication	Fortran Target Accelerators	Use 24-bit multiplication for subscripting. (-ta=nvidia:mul24)
NVIDIA: Use Fast Math Library	Fortran Target Accelerators	Use routines from the fast math library. (-ta=nvidia:fastmath)
NVIDIA: Use Fused Multiply-Adds	Fortran Target Accelerators	Control generation of fused multiply-add (FMA) instructions. Yes: Enables generation of FMA. (default) No: Disables generation of FMA. (-ta=nvidia:nofma)
Number of Cores	Debugging [Cluster MPI]	Select the number of cores on which to run.
Number of Processes	Debugging [Local MPI]	Select the number of processes to use to run.
Object File Name	Fortran General	File level: Set the name of the object file using the <code>-o</code> switch. Project level: Set the location of the object files created by a build.
OpenMP Information	Fortran Diagnostics	Generate information about OpenMP. (-Minfo=mp)
Optimization	Fortran General	Select the overall code optimization.
Optimization	Fortran Optimization	Select the overall code optimization.
Optimization Information	Fortran Diagnostics	Generate information about general optimizations. (-Minfo=opt)
Output Directory	General	Specify a relative path to the output file directory. This directory is where the project's output files will be built.
Output File	Librarian General	Override the default output file name.
Output File	Linker General	Override the default output file name.

Use this Property...	From this Property Page...	To do this...
Outputs	Custom Build Step General	Specify the files generated by the custom build step.
Parallelization Information	Fortran Diagnostics	Generate information about parallel optimizations (-Minfo=par)
Preprocessor Definitions	Fortran Preprocessing	Add one or more preprocessor definitions to compilation.
Preprocess Source File	Fortran Preprocessing	Specify whether the compiler should preprocess source files or not.
Enable OpenMP Directives	Fortran Language	Enable OpenMP 3.0 language extensions. (-mp)
Runtime Library	Fortran Code Generation	Specify what type of runtime libraries should be used during linking. (-Bstatic) (-Bdynamic) Note. You must keep the runtime libraries consistent within a solution.
Stack Commit Size	Linker General	Specify the total number of bytes for stack allocation in physical memory. Use decimal notation. -stack=reserve,commit
Stack Reserve Size	Linker General	Specify the total number of bytes for stack allocation in virtual memory. Use decimal notation. -stack=reserve
Standard Error	Debugging [Cluster MPI]	Specify a file to be used for standard error for MPI cluster running or debugging.
Standard Input	Debugging [Cluster MPI]	Specify a file to be used as standard input for MPI cluster running or debugging.
Standard Output	Debugging [Cluster MPI]	Specify a file to be used as standard output for MPI cluster running or debugging.
String Length Arguments	Fortran External Procedures	Specify where string length arguments are placed in the argument list. (-Miface= [no]mixed_str_len_arg)
Suppress CCFF Information	Fortran Profiling	Suppress profiling's default generation of CCFF information. (-Mprof=noccf)

Use this Property...	From this Property Page...	To do this...
Target Host	Fortran Target Accelerators	Generate code just for the host if no accelerator is selected. Otherwise, generate PGI Unified Binary Code for the host and accelerator. (-ta=host)
Target NVIDIA Accelerator	Fortran Target Accelerators	Select NVIDIA accelerator target. (-ta=nvidia)
Treat Backslash as Character	Fortran Language	Yes: Treat the backslash ('\') as a regular character. (-Mbackslash) No: Treat the backslash ('\') as an escape character. (-Mnbackslash)
Treat Denormalized Values as Zero	Fortran Floating Point Options	Default: Accept the default treatment of denormalized floating point values. Yes: Enable the treatment of denormalized floating point values as zero. (-Mdaz) No: Disable the treatment of denormalized floating point values as zero. (-Mnodaz)
Undefine Preprocessor Definitions	Fortran Preprocessing	Undefine one or more preprocessor definitions.
Unified Binary Information	Fortran Diagnostics	Generate information specific to the PGI Unified Binary (-Minfo=unified)
Use ACML	Fortran Libraries	Specify if generated code uses the AMD Core Math Library. Yes: Generate code that uses the AMD Core Math Library. No: Generate code that does not use the AMD Core Math Library.
Use Frame Pointer	Fortran Optimization	Specify if generated code uses a frame pointer. Yes: Generate code that uses a frame pointer. (-Mframe) No: Generate code that does not use a frame pointer. (-Mnoframe)

Use this Property...	From this Property Page...	To do this...
Use IMSL	Fortran Libraries	Specify if generated code uses the Rogue Wave IMSL numerical libraries. Yes: Generate code that uses the Rogue Wave IMSL numerical libraries. No: Generate code that does not use the Rogue Wave IMSL numerical libraries.
Use MKL	Fortran Libraries	Specify if generated code uses intel's Math Kernel Library. Yes: Generate code that uses the Intel Math Kernel Library. No: Generate code that does not use the Intel Math Kernel Library.
Vectorization	Fortran Optimization	Specify the type of vectorization to perform. (-Mvect)
Vectorization Information	Fortran Diagnostics	Generate vectorization information. (-Minfo=vect)
Warning Level	Fortran Diagnostics	Select the level of diagnostic reporting you want the compiler to use. (-Minform=inform warn severe fatal)
Working Directory	Debugging [Cluster MPI]	Specify the application's working directory for MPI cluster running or debugging.
Working Directory	Debugging [Local MPI]	Specify the application's working directory for local MPI running or debugging.
Working Directory	Debugging [Serial]	Specify the application's working directory for serial running or debugging.

General Property Page

This section contains the properties that are included on the General property page.

General

Output Directory

Use this property to specify a relative path to the output file directory. This directory is where the project's output files are built.

Intermediate Directory

Use this property to specify a relative path to the intermediate file directory. This directory is where the intermediate files (i.e., object files) are created when the project is built.

Extensions to Delete on Clean

Use this property to specify which files in the intermediate directory should be deleted when the project is cleaned or before it is rebuilt. This property uses a semi-colon-delimited wildcard specification for the files.

Configuration Type

Use this property to change the output type that the project produces.

When you create a project, you specify the type of output that the project produces: executable, static library, or dynamic library. If you want to change the output type, use this property to do so.

Build Log File

Use this property to specify the build log file that is produced when the project is built.

Build Log Level

Use this property to specify the level of detail to be included in the build log file.

Note

Any setting above Default can produce large amounts of output and may potentially slow down the building of your project.

Debugging Property Page

This section contains the properties that are included on the Debugging property page.

Debugging

Application Command

Use this property to specify the application to execute when you select *Start Debugging* or *Start Without Debugging* from the *Debug* menu.

- If the Startup Project in your solution is a PVF project that builds an executable, there is probably no need to change this property.
- If the Startup Project in your solution is a PVF project that builds a DLL or static library, you must use the Command property to specify an application to execute when you run (with or without debugging).

Note

To use the PVF debug engine, the Startup Project must be a PVF project. If, for example, your main executable is built by a Visual C++ project that links against a PVF project, you would designate the PVF project as the Startup Project; and in its Debugging | Application Command property, you would specify the path to the executable built by the Visual C++ project.

Tip

The Startup Project is the project listed in boldface in the solution explorer. You can change the Startup Project by right-clicking on any project in the solution explorer and selecting *Set as Startup Project* from the context menu.

Application Arguments

Use this property to pass command line arguments to the application when it is run or debugged.

Environment

Use this property to specify any environment variables to set for the application when it runs. One common use of this property is to augment the `PATH` environment variable. For example, if the application requires DLLs to run but the general environment is not set to find these, the path to these DLLs could be added to the `PATH` environment variable.

For more information on `PATH`, refer to the PGI Compiler User's Guide.

If the Merge Environment property is set to `Yes`, then the contents of the Environment property are merged with the existing environment when the application is run or debugged.

Merge Environment

Use this property to merge the environment variables in the Environment property with the existing environment when the application is run or debugged. To do this, set the Merge Environment property to `Yes`.

MPI Debugging

Use this property to enable MPI debugging and select between local MPI debugging and cluster MPI debugging.

The value selected for this property determines which properties are displayed following it on the Debugging property page.

Important

If you change the value of this property and the displayed properties do not change, be sure to click Apply in the property page dialog box.

- When MPI Debugging is set to *Disabled*, the application is run or debugged in serial mode.
- When MPI Debugging is set to *Local*, the application is run or debugged using `mpiexec`. All processes launched are local to the system on which the application is run.
- When MPI Debugging is set to *Cluster*, the application is launched for running or debugging using the Microsoft HPC Job Manager via the `job submit` command. Some or all of the processes launched as part of execution may be on remote nodes.

A PGI license that supports running or debugging MPI processes on remote clusters is required for this option to be available. For information about upgrading your current license to a cluster license, contact sales@pgroup.com.

Working Directory

[Serial]

Use this property to specify the application's working directory when it is run or debugged serially. By default, the working directory is set to the solution directory.

This property is displayed when the MPI Debugging property is set to *Disabled*.

Number of Processes

[Local MPI]

Use this property to specify the number of MPI processes to use when the application is run or debugged. The number of processes is passed to `mpiexec` using the `-n` option.

This property is displayed when the MPI Debugging property is set to *Local*.

Working Directory

[Local MPI]

Use this property to specify the application's working directory when it is run or debugged using local MPI. By default, the working directory is set to the solution directory.

This property is displayed when the MPI Debugging property is set to *Local*.

Additional Arguments: mpiexec

[Local MPI]

Use this property to specify additional arguments to be passed to `mpiexec` when the application is run or debugged.

This property is displayed when the MPI Debugging property is set to *Local*.

Location of mpiexec

[Local MPI]

Use this property to override the default path to `mpiexec` as specified in the system `PATH` variable.

This property is displayed when the MPI Debugging property is set to *Local*.

Number of Cores

[Cluster MPI]

Use this property to specify the number of cores with which to run or debug the MPI application. The value of this property is passed to the `job submit` command using the `/numcores` option.

This property is displayed when the MPI Debugging property is set to *Cluster*.

Working Directory

[Cluster MPI]

Use this property to specify the application's working directory when it is run or debugged using MPI on a cluster. The value of this property will be passed to the `job submit` command using the `/workdir` option. By default, the working directory is set to the solution directory.

This property is displayed when the MPI Debugging property is set to *Cluster*.

Note

The working directory specified for cluster debugging must be a directory specified as *shared* among all the nodes on the cluster. Execution of the application fails if the working directory is not marked *shared*. For assistance designating a directory as *shared*, contact the system administrator.

Standard Input

[Cluster MPI]

Use this property to specify a file to be used as standard input by the MPI application running on a cluster. This file is passed to the `job submit` command using the `/stdin` option.

This property is displayed when the MPI Debugging property is set to *Cluster*.

By default, the `job submit` command searches for the input file in the application's working directory. If the input file is in a location other than the working directory, specify a full path to the file.

Standard Output

[Cluster MPI]

Use this property to specify a file to be used for standard output by the MPI application running on a cluster. This file will be passed to the `job submit` command using the `/stdout` option.

This property is displayed when the MPI Debugging property is set to *Cluster*.

By default, the `job submit` command creates the output file in the application's working directory. To create the output file in a location other than the working directory, specify a full path to the file.

Standard Error

[Cluster MPI]

Use this property to specify a file to be used for standard error by the MPI application running on a cluster. This file is passed to the `job submit` command using the `/stderr` option.

This property is displayed when the MPI Debugging property is set to *Cluster*.

By default, the `job submit` command creates the error file in the application's working directory. If the error file is in a location other than the working directory, specify a full path to the file.

Note

To capture the standard error output by an MPI cluster application, a file must be specified in the *Standard Error* property.

Additional Arguments: job submit

[Cluster MPI]

Use this property to specify additional arguments to be passed to the `job submit` command when the application is run or debugged.

This property is displayed when the MPI Debugging property is set to *Cluster*.

Additional Arguments: mpiexec

[Cluster MPI]

Use this property to specify additional arguments to be passed to `mpiexec` when the application is run or debugged.

This property is displayed when the MPI Debugging property is set to *Cluster*.

Location of job.exe

[Cluster MPI]

Use this property to override the default path to `job.exe` as specified in the system PATH variable.

This property is displayed when the MPI Debugging property is set to *Cluster*.

Fortran Property Pages

This section contains the property pages that are included in the Fortran category. This category is further divided into the following property pages, displayed in the following order:

- General
- Optimization
- Preprocessing
- Code Generation
- Language
- Floating Point Options
- External Procedures
- Target Processors
- Target Accelerators
- Diagnostics
- Profiling
- Command Line

The following sections describe the properties available on each property page.

Fortran | General

The following properties are available from the Fortran | General property page.

Display Startup Banner

Use this property to determine whether to display the compiler's startup banner during compilation.

Changing the property to `Yes` adds the `-v` switch to the compilation line, which causes the compiler to display the startup banner during compilation.

For more information on `-v`, refer to [Chapter 2, “Command-Line Options Reference”](#).

Additional Include Directories

Use this property to add one or more directories to the compiler's include path.

For every path that is added to this property, PVF adds `-I<path>` to the compilation line.

There are two ways to add directories to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each directory.

- Click the ellipsis (...) button in the property page box to open the *Additional Include Directories* dialog box.

Enter each directory on its own line in this box. Do not use semi-colons to separate directories; the semi-colons are added automatically when the box is closed.

Note

This property is also available from the [Fortran | Preprocessing](#) property page.

Module Path

Use this property to specify the location of module (.mod) files.

For every directory that is added to this property, PVF adds `-module <dir>` to the compilation line, causing the compiler to search each listed directory for modules during compilation.

Note

The first directory in the list is also the module output directory, which is where PVF puts all module files created when the project is built.

There are two ways to add directories to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each path.

- Click the ellipsis (...) button in the property page box to open the *Module Path* dialog box.

Enter each directory on its own line in this box. Do not use semi-colons to separate entries; the semi-colons are added automatically when the box is closed.

Object File Name

Use of this property depends on whether it is being applied to a file or a project:

- File level: Use this property to set the name of the object file. Setting the name adds the `-o` switch to the compilation line.

For more information on `-o`, refer to [“-o,” on page 33](#).

- Project level: Use this property to set the location of the object files created by a build.

To change the default location for the object files, specify a different directory name for this property.

Note

You must append a backslash (\) to the directory path or the value of this property will be interpreted as a file.

Debug Information Format

Use this property to specify whether the compiler should generate debug information and if so, in what format.

- The richest debugging experience is obtained when this option is set to "Full Debug Information ([-g](#))."
- If you are debugging a project built with optimizations, you may want to select "Full Debug Information with Full Optimization ([-gopt](#)).". This selection prevents the generation of debug information from affecting optimizations.

For more information on `-g`, refer to "[-g](#)," on [page 17](#). For more information on `-gopt`, refer to "[-gopt](#)," on [page 18](#).

Optimization

Use this property to select the overall code optimization.

This property can be set to one of the following values:

- **No Optimization** - the default value for Debug configurations.
- **Maximize Speed** - the default value for Release Configurations.
- **Maximize Speed Across the Whole Program**

Note

This property is also available from the [Fortran | Optimization](#) property page.

Fortran | Optimization

The following properties are available from the Fortran | Optimization property page.

Optimization

Use this property to select the overall code optimization.

This property can be set to one of the following values:

- **No Optimization** - the default value for Debug configurations.
- **Maximize Speed** - the default value for Release Configurations.
- **Maximize Speed Across the Whole Program**

Note

This property is also available from the Fortran | General property page.

Global Optimizations

Use this property to set the compiler's global optimization level. Setting this property adds one of the `-O` options to the compilation line.

For more information on `-O`, refer to [“`-O<level>`,” on page 32](#).

Vectorization

Use this property to specify the type of vectorization to perform.

The PVF compilers use the `-Mvect` options to vectorize code that is vectorizable. Select the appropriate vectorization from these options:

- **Default:** Accepts the default vectorization.
- **Enable Vectorization:** Enables vectorization by adding the `-Mvect` switch to the PVF compilation and link lines.
- **Vectorize using SSE instructions:** Enables vectorization using SSE instructions by adding the `-Mvect=sse` switch to the PVF compilation line.
- **Vectorize using SIMD instructions:** Enables vectorization using SIMD instructions and data, by adding the `-Mvect=simd` switch to the PVF compilation line.
- **Vectorize using 128-bit SIMD instructions:** Enables vectorization using SIMD 128-bit instructions and data, by adding the `-Mvect=simd:128` switch to the PVF compilation line.
- **Vectorize using 256-bit SIMD instructions:** Enables vectorization using SIMD 256-bit instructions and data, by adding the `-Mvect=simd:256` switch to the PVF compilation line.

For more information on `-Mvect`, refer to [“Optimization Controls,” on page 60](#).

Inlining

Use this property to enable inlining of certain subprograms.

Setting this property to `Yes` adds the `-Minline` switch to the compilation command line.

For more information on `-Minline`, refer to [“Optimization Controls,” on page 60](#).

Use Frame Pointer

Use this property to specify whether to generate code that uses a frame pointer.

Setting this property to `Yes` adds the `-Mframe` switch to the compilation command line and PVF compilers generate code that uses a frame pointer.

Setting this property to `No`, the default, adds the `-Mnoframe` switch to the compilation command line and PVF compilers generate code that does not use frame pointers.

For more information on `-Mframe`, refer to [“Optimization Controls,” on page 60](#).

Loop Unroll Count

Use this property to select the appropriate value for unrolling.

Loop unrolling is a common optimization. This property allows you to specify unrolling by two or four. Using this option adds the `-Munroll` option to the compilation line.

For more information on `-Munroll`, refer to [“Optimization Controls,” on page 60](#).

Auto-Parallelization

Use this property to auto-parallelize code that is parallelizable. Using this option adds the `-Mconcur` option to the compilation line.

For more information on `-Mconcur`, refer to [“Optimization Controls,” on page 60](#).

Fortran | Preprocessing

The following properties are available from the Fortran | Preprocessing Property page.

Preprocess Source File

Use this property to specify whether the compiler should preprocess source files.

Setting this property to `Yes` adds the `-Mpreprocess` switch to the compilation command line.

For more information on `-Mpreprocess`, refer to [“Miscellaneous Controls,” on page 70](#).

Additional Include Directories

Use this property to add one or more directories to the compiler’s include path.

For every path that is added to this property, PVF adds `-I<path>` to the compilation line.

There are two ways to add directories to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each directory.

- Click the ellipsis (...) button in the property page box to open the *Additional Include Directories* dialog box.

Enter each directory on its own line in this box. Do not use semi-colons to separate directories; the semi-colons are added automatically when the box is closed.

For more information on `-I<path>`, refer to [“-I,” on page 20](#).

Note

This property is also available from the [Fortran | General](#) property page.

Ignore Standard Include Path

Use this property to specify whether the preprocessor should ignore the standard include path.

Setting this property to `Yes` adds the `-Mnostdinc` switch to the compilation command line.

For more information on `-Mnostdinc`, refer to [“Environment Controls,” on page 53](#).

Preprocessor Definitions

Use this property to add one or more preprocessor definitions to compilation.

For every definition that is added to this property, PVF adds `-D<definition>` to the compilation line.

There are two ways to add definitions to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each definition.

For example, `DEF1;DEF2=2` defines `DEF1`, and defines `DEF2` and initializes it to 2.

- Click the ellipsis (...) button in the property page box to open the *Preprocessor Definitions* dialog box.

Enter each definition on its own line in this box. Do not use semi-colons to separate definitions; the semi-colons are added automatically when the box is closed.

For more information on `-D<definition>`, refer to [“-D,” on page 13](#).

Undefine Preprocessor Definitions

Use this property to undefine one or more preprocessor definitions.

For every definition that is added to this property, PVF adds `-U<definition>` to the compilation line.

There are two ways to add definitions to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each definition.

For example, `DEF1;DEF2` undefines `DEF1` and `DEF2`.

- Click the ellipsis (...) button in the property page box to open the *Undefine Preprocessor Definitions* dialog box.

Enter each definition on its own line in this box. Do not use semi-colons to separate definitions; the semi-colons are added automatically when the box is closed.

For more information on `-U<definition>`, refer to [“-U,” on page 46](#).

Fortran | Code Generation

The following properties are available from the Fortran | Code Generation property page.

Runtime Library

Use this property to specify the type of runtime libraries to use during linking.

Default: Depends on the project:

- *For executable and static library projects:* multi-threaded static libraries.

Using this option adds the `-Bstatic` option to the compilation line. This choice corresponds to Microsoft's `/MT` compilation option.

For more information on `-Bstatic`, refer to [“-Bstatic,” on page 11](#).

- *For dynamic-link library projects:* multi-threaded DLL libraries.

Using this option adds the `-Bdynamic` option to the compilation line. This choice corresponds to Microsoft's `/MD` compilation option.

For more information on `-Bstatic`, refer to [“-Bdynamic,” on page 10](#).

Note

It is important to keep the type of runtime libraries consistent within a solution. PVF projects that build DLLs should link to the multi-threaded DLL runtime, and projects that link to these PVF DLLs should also use the multi-threaded DLL runtime.

Fortran | Language

The following properties are available from the [Fortran | Language](#) property page.

Fortran Dialect

Use this property to select the Fortran dialect to use during compilation.

PVF supports two Fortran language dialects: Fortran 95 and FORTRAN 77. The dialect determines which PGI compiler driver is used during compilation.

- **Default:** The dialect is set to Fortran 95, even for fixed-format `.f` files, and the `pgfortran` driver is used.
- **Fortran 77:** Use the `pgf77` driver. You can select the FORTRAN 77 dialect at the project or file level.

Treat Backslash as Character

Use this property to specify how the compilers should treat the backslash (`\`) character.

Default: PVF treats the backslash (`\`) as a regular character.

This default action is equivalent to adding the `-Mbackslash` switch to compilation.

If you want the backslash character to be treated as an escape character, which is how C and C++ compilers handle backslashes, set this property to `No`.

For more information on `-Mbackslash`, refer to [“Fortran Language Controls,” on page 54](#).

Extend Line Length

Use this property to extend the line length for fixed-format Fortran files to 132 characters.

Fixed-format Fortran files limit the accepted line length to 72 characters. To extend the line length for these types of files to 132 characters, set this property to `Yes`, which adds the `-Mextend` switch to the PVF compilation line.

For more information on `-Mextend`, refer to [“Fortran Language Controls,” on page 54](#).

Enable OpenMP Directives

Use this property to enable OpenMP 3.0 language extensions.

Setting this property to `Yes` adds the `-mp` switch to the PVF compilation and link lines.

For more information on `-mp`, refer to [“`-mp \[=all, align, bind, \[no\] numa\]`,” on page 31](#).

MPI

Use this property to enable compilation and linking using the Microsoft MPI headers and libraries.

Setting this property to `Microsoft MPI` adds the `-Mmpi=msmpi` switch to the PVF compilation and link lines.

Enable CUDA Fortran

Use this property to enable CUDA Fortran.

Setting this property to `Yes` adds the `-Mcuda` switch to the PVF compilation and link lines and activates access to these additional properties:

- [CUDA Fortran Register Limit](#)
- [CUDA Fortran Use Fused Multiply-Adds](#)
- [CUDA Fortran Use Fast Math Library](#)
- [CUDA Fortran Flush to Zero](#)
- [CUDA Fortran Toolkit](#)
- [CUDA Fortran Compute Capability](#)
- [CUDA Fortran Keep Binary](#)
- [CUDA Fortran Keep Kernel Source](#)
- [CUDA Fortran Keep PTX](#)
- [CUDA Fortran Emulation](#)

Important

If you select `Yes` and the additional properties do not appear, click `Apply` in the Property page dialog.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Register Limit

When Enable CUDA Fortran is set to `Yes`, use this property to specify the number of registers to use on the GPU.

Setting this property to an integer value, `n`, adds the `-Mcuda=maxregcount:n` switch to the PVF compilation and link lines.

Leaving this property blank indicates no limit to the number of registers to use on the GPU.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Use Fused Multiply-Adds

When Enable CUDA Fortran is set to `Yes`, use this property to control the generation of fused multiply-add (FMA) instructions.

Setting this property to `Yes` enables generation of FMA instructions; this is the default.

Setting this property to `No` adds the `-Mcuda=nofma` switch to the PVF compilation and link lines.

CUDA Fortran Use Fast Math Library

When Enable CUDA Fortran is set to `Yes`, use this property to use routines from the fast math library.

Setting this property to `Yes` adds the `-Mcuda=fastmath` switch to compilation and linking.

CUDA Fortran Flush to Zero

Use this property to control flush-to-zero mode for floating point computations on in GPU code generated for CUDA Fortran kernels.

- **Default:** Accepts the default handling of floating point computations in the GPU code generated for CUDA Fortran kernels.
- **Yes:** Enables flush-to-zero mode by adding the `-Mcuda=flushz` switch to the PVF compilation and link lines.
- **No:** Disables flush-to-zero mode by adding the `-Mcuda=noflushz` switch to the PVF compilation and link lines.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Toolkit

When Enable CUDA Fortran is set to `Yes`, use this property to specify the version of the CUDA toolkit that is targeted by the compilers.

- **Default:** The compiler selects the default CUDA toolkit version.
- **2.3:** Use version 2.3 of the CUDA toolkit. This selection adds the `-Mcuda=cuda2.3` switch to the PVF compilation and link lines.

- **3.0:** Use version 3.0 of the CUDA toolkit. This selection adds the `-Mcuda=cuda3.0` switch to the PVF compilation and link lines.
- **3.1:** Use version 3.1 of the CUDA toolkit. This selection adds the `-Mcuda=cuda3.1` switch to the PVF compilation and link lines.
- **3.2:** Use version 3.2 of the CUDA toolkit. This selection adds the `-Mcuda=cuda3.2` switch to the PVF compilation and link lines.
- **4.0:** Use version 4.0 of the CUDA toolkit. This selection adds the `-Mcuda=cuda4.0` switch to the PVF compilation and link lines.
- **4.1:** Use the default version 4.1 of the CUDA toolkit. This selection adds the `-Mcuda=cuda4.1` switch to the PVF compilation and link lines.
- **4.2:** Use version 4.2 of the CUDA toolkit. This selection adds the `-Mcuda=cuda4.2` switch to the PVF compilation and link lines.

Note

Compiling with the CUDA 3.1 or higher toolkit, either by setting the appropriate property as just described or by adding `set CUDAVERSION=3.1`, `set CUDAVERSION=3.2`, `set CUDAVERSION=4.0`, `set CUDAVERSION=4.1`, or `set CUDAVERSION=4.2` to the `siterc` file, generates binaries that may not work on machines with a 2.3 CUDA driver.

`pgaccelinfo` prints the driver version as the first line of output.

```
For a 2.3 driver:  CUDA Driver Version 2030
For a 3.0 driver:  CUDA Driver Version 3000
For a 3.1 driver:  CUDA Driver Version 3010
For a 3.2 driver:  CUDA Driver Version 3020
For a 4.0 driver:  CUDA Driver Version 4000
For a 4.1 driver:  CUDA Driver Version 4010
For a 4.2 driver:  CUDA Driver Version 4020
```

For more information on `-Mcuda`, refer to [“Fortran Language Controls,” on page 54](#).

CUDA Fortran Compute Capability

When `Enable CUDA Fortran` is set to `Yes`, use this property to either automatically generate code compatible with all applicable compute capabilities, or to direct the compiler to use a manually-selected set.

Select either `Automatic` or `Manual`.

- **Automatic:** Let the compiler generate code for all applicable compute capabilities. This is the default.
- **Manual:** Choose one or more compute capabilities to target. The compiler generates code for each capability specified.

If you select `Manual`, then you can select any or all of the following compute capabilities that are described in the next sections.

[CUDA Fortran CC 1.0](#)

[CUDA Fortran CC 1.1](#)[CUDA Fortran CC 1.2](#)[CUDA Fortran CC 1.3](#)[CUDA Fortran CC 2.0](#)[CUDA Fortran CC 3.0](#)

Important

If you select `Manual` and the additional properties do not appear, click `Apply` in the `Property` page dialog.

For more information on `-Mcuda`, refer to [“Optimization Controls,”](#) on page 60.

CUDA Fortran CC 1.0

When `Enable CUDA Fortran` is set to `Yes` and `CUDA Fortran Compute Capability` is set to `Manual`, use this property to generate code for CUDA compute capability 1.0.

Setting this property to `Yes` adds the `-Mcuda=cc10` switch to the PVF compilation and link lines.

CUDA Fortran CC 1.1

When `Enable CUDA Fortran` is set to `Yes` and `CUDA Fortran Compute Capability` is set to `Manual`, use this property to generate code for CUDA compute capability 1.1.

Setting this property to `Yes` adds the `-Mcuda=cc11` switch to the PVF compilation and link lines.

CUDA Fortran CC 1.2

When `Enable CUDA Fortran` is set to `Yes` and `CUDA Fortran Compute Capability` is set to `Manual`, use this property to generate code for CUDA compute capability 1.2.

Setting this property to `Yes` adds the `-Mcuda=cc12` switch to the PVF compilation and link lines.

CUDA Fortran CC 1.3

When `Enable CUDA Fortran` is set to `Yes` and `CUDA Fortran Compute Capability` is set to `Manual`, use this property to generate code for CUDA compute capability 1.3.

Setting this property to `Yes` adds the `-Mcuda=cc13` switch to the PVF compilation and link lines.

CUDA Fortran CC 2.0

When `Enable CUDA Fortran` is set to `Yes` and `CUDA Fortran Compute Capability` is set to `Manual`, use this property to generate code for CUDA compute capability 2.0.

Setting this property to `Yes` adds the `-Mcuda=cc20` switch to the PVF compilation and link lines.

CUDA Fortran CC 3.0

When `Enable CUDA Fortran` is set to `Yes` and `CUDA Fortran Compute Capability` is set to `Manual`, use this property to generate code for CUDA compute capability 3.0.

Setting this property to `Yes` adds the `-Mcuda=cc30` switch to the PVF compilation and link lines.

CUDA Fortran Keep Binary

Use this property to keep the CUDA binary (.bin) file.

Setting this property to `Yes` adds the `-Mcuda=keepbin` switch to the PVF compilation and link lines.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Keep Kernel Source

When Enable CUDA Fortran is set to `Yes`, use this property to keep the kernel source files.

Setting this property to `Yes` adds the `-Mcuda=keepgpu` switch to the PVF compilation and link lines.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Keep PTX

When Enable CUDA Fortran is set to `Yes`, use this property to keep the portable assembly (.ptx) file for the GPU code.

Setting this property to `Yes` adds the `-Mcuda=keepptx` switch to the PVF compilation and link lines.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Keep PTXAS

Use this property to show PTXAS informational messages during compilation.

Setting this property to `Yes` adds the `-Mcuda=ptxinfo` switch to the PVF compilation and link lines.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

CUDA Fortran Emulation

When Enable CUDA Fortran is set to `Yes`, use this property to enable CUDA Fortran emulation mode.

Setting this property to `Yes` adds the `-Mcuda=emu` switch to the PVF compilation and link lines.

For more information on `-Mcuda`, refer to [“Optimization Controls,” on page 60](#).

Fortran | Floating Point Options

The following properties are available from the Fortran | Floating Point Options property page.

Floating Point Exception Handling

Use this property to enable floating point exceptions.

Setting this property to `Yes` adds the `-Ktrap=fp` option to compilation.

For more information on `-Ktrap`, refer to [“-K<flag>,” on page 21](#).

Floating Point Consistency

Use this property to enable relaxed floating point accuracy in favor of speed.

Setting this property to `Yes` adds the `-Mfprelaxed` option to compilation.

For more information on `-Mfprelaxed`, refer to [“Optimization Controls,” on page 60](#).

Flush Denormalized Results to Zero

Use this property to specify how to handle denormalized floating point results.

- **Default:** Accepts the default handling of denormalized floating point results.
- **Yes:** Enables SSE flush-to-zero mode using the `-Mflushz` compilation option.
- **No:** Disables SSE flush-to-zero mode using the `-Mnoflushz` compilation option.

For more information on `-M[no]flushz`, refer to [“Code Generation Controls,” on page 49](#).

Treat Denormalized Values as Zero

Use this property to specify how to treat denormalized floating point values.

- **Default:** Accept the default treatment of denormalized floating point values.
- **Yes:** Enable the treatment of denormalized floating point values as zero using the `-Mdaz` compilation option.
- **No:** Disable the treatment of denormalized floating point values as zero using the `-Mnodaz` compilation option.

For more information on `-M[no]daz`, refer to [“Code Generation Controls,” on page 49](#).

IEEE Arithmetic

Use this option to specify IEEE floating point arithmetic.

- **Default:** Accept the default floating point arithmetic.
- **Yes:** Enable IEEE floating point arithmetic using the `-Kieee` compilation option.
- **No:** Disable IEEE floating point arithmetic using the `-Knoieee` compilation option.

For more information on `-K[no]ieee`, refer to [“-K<flag>,” on page 21](#).

Fortran | External Procedures

The following properties are available from the Fortran | External Procedures property page.

Calling Convention

Use this property to specify an alternate Fortran calling convention.

- **Default:** Accept the default calling convention.
- **C By Reference:** Use the CREF calling convention. Adds `-Miface=cref` to compilation. On both Win32 and x64 platforms, no trailing underscores are used with this option. On the x64 platform, this option also causes Fortran externals to be uppercase and lengths of character arguments to be put at the end of the argument list.
- **Unix:** [Win32 platform only] Use the Unix calling convention. Adds `-Miface=unix` to compilation. No trailing underscores are used with this option.

For more information on `-Miface`, refer to [“Miscellaneous Controls,” on page 70](#).

String Length Arguments

Use this property to change where string length arguments are placed in the argument list.

- **Default:** Use the calling convention's default placement for passing string length arguments.
- **After Every String Argument:** Lengths of character arguments are placed immediately after their corresponding argument. This option adds `-Miface=mixed_str_len_arg` to compilation.
- **After All Arguments:** Places lengths of character arguments at the end of the argument list. This option adds `-Miface=nomixed_str_len_arg` to the compilation.

Note

The *After Every String Argument* and *After All Arguments* options only have an effect when using the C By Reference calling convention.

For more information on `-Miface`, refer to [“Miscellaneous Controls,” on page 70](#).

Case of External Names

Use this property to specify the case used for Fortran external names.

- **Default:** Use the calling convention's default case for external names.
- **Lower Case:** Make Fortran external names lower case. This option adds `-Mnames=lowercase` to the compilation.
- **Upper Case:** Make Fortran external names upper case. This option adds `-Mnames=uppercase` to the compilation.

Note

The Lower Case and Upper Case options only have an effect when using the C By Reference calling convention.

Fortran | Libraries

The Fortran | Libraries property page contains properties that make it easier to use third-party libraries. To use these libraries, however, the appropriate binaries, such as `.lib` and `.dll` files, must be installed on your system.

Use ACML

Use this property to build for and link against the AMD Core Math Library (ACML). PGI products include a version of the ACML.

- **Yes:** Use the AMD Core Math Library when building and linking programs.
- **No:** Do not use the AMD Core Math Library when building and linking programs.

Use IMSL

Use this property to build for and link against the Rogue Wave IMSL numerical libraries. T, which are available from Rouge Wave Software.

- **Yes:** Use the Rogue Wave IMSL numerical libraries when building and linking programs.
- **No:** Do not use the Rogue Wave IMSL numerical libraries when building and linking programs.

Use MKL

Use this property to build for and link against the Intel Math Kernel Library (MKL), which is available from Intel.

- **Yes:** Use the Intel Math Kernel Library when building and linking programs.
- **No:** Do not use the Intel Math Kernel Library when building and linking programs.

Fortran | Target Processors

The properties that are available from the Fortran | Target Processors property page depend on the platform you are using. The platform selection box in the center of the Property Pages dialog indicates the platform: `x64` or `Win32`.

Note

x64 Platform

You can target multiple processors for optimization on the x64 platform.

Win32 Platform

You can target only one processor at a time for optimization on the Win32 platform. If you select `Yes` for more than one processor, a compiler error occurs.

The Target Processors properties add the `-tp=<target>` option to compilation. For more information on the `-tp` switch referenced throughout the following descriptions, refer to [-tp](#).

AMD Athlon

Use this property to optimize for AMD Athlon64, AMD Opteron and compatible processors.

x64: Setting this property to `Yes` adds the `-tp=k8-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=k8-32` switch to the compilation.

AMD Barcelona

Use this property to optimize for AMD Opteron/Quadcore and compatible processors.

x64: Setting this property to `Yes` adds the `-tp=barcelona-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=barcelona-32` switch to the compilation.

AMD Bulldozer

Use this property to optimize for AMD Bulldozer and compatible processors.

x64: Setting this property to `Yes` adds the `-tp=bulldozer-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=bulldozer-32` switch to the compilation.

AMD Istanbul

Use this property to optimize for AMD Istanbul processor-based systems.

x64: Setting this property to `Yes` adds the `-tp=istanbul-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=istanbul-32` switch to the compilation.

AMD Shanghai

Use this property to optimize for AMD Shanghai processor-based systems.

x64: Setting this property to `Yes` adds the `-tp=shanghai-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=shanghai-32` switch to the compilation.

Intel Core 2

Use this property to optimize for Intel Core 2 Duo and compatible processors.

x64: Setting this property to `Yes` adds the `-tp=core2-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=core2-32` switch to the compilation.

Intel Core i7

Use this property to optimize for Intel Core i7 (Nehalem) processor-based systems.

x64: Setting this property to `Yes` adds the `-tp=nehalem-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=nehalem-32` switch to the compilation.

Intel Penryn

Use this property to optimize for Intel Penryn architecture and compatible processors.

x64: Setting this property to `Yes` adds the `-tp=penryn-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=penryn-32` switch to the compilation.

Intel Pentium 4

Use this property to optimize for Intel Pentium 4 and compatible processors.

Win32: Setting this property to `Yes` adds the `-tp=p7-32` switch to the compilation.

Intel Sandy Bridge

Use this property to optimize for Intel Sandy Bridge architecture and compatible processors.

x64: Setting this property to `Yes` adds the `-tp=sandybridge-64` switch to the compilation.

Win32: Setting this property to `Yes` adds the `-tp=sandybridge-32` switch to the compilation.

Generic x86 [Win32 only]

Use this property to optimize for any x86 processor-based system.

x64: N/A

Win32: Setting this property to `Yes` adds the `-tp=px-32` switch to the compilation.

Generic x86-64 [x64 only]

Use this property to optimize for any x86-64 processor-based system.

x64: Setting this property to `Yes` adds the `-tp=px-64` switch to the compilation.

Win32: N/A

Fortran | Target Accelerators

The following properties are available from the Fortran | Target Accelerators property page.

For more information about the PGI Accelerator or on the options in this section, refer to the PGI Compiler User's Guide.

Target NVIDIA Accelerator

Use this property to select NVIDIA accelerator target.

Setting this property to `Yes` adds the `-ta=nvidia` switch to the compilation line and activates access to these additional properties:

[NVIDIA: Register Limit](#)

[NVIDIA: Use Fused Multiply-Adds](#)

[NVIDIA: Use Fast Math Library](#)

[NVIDIA: Flush to Zero](#)

[NVIDIA: Use 24-bit Subscript Multiplication](#)

[NVIDIA: Synchronous Kernel Launch](#)

[NVIDIA: CUDA Toolkit](#)

[NVIDIA: Compute Capability](#)

[NVIDIA: Keep Kernel Binary](#)

[NVIDIA: Keep Kernel Source](#)

[NVIDIA: Keep Kernel PTX](#)

[NVIDIA: Enable Profiling](#)

[NVIDIA: Analysis Only](#)

Important

If you change the value of this property and the displayed properties do not change, be sure to click Apply in the property page dialog box.

NVIDIA: Register Limit

Use this property to specify the number of registers to use on the GPU.

Setting this property to an integer value, *n*, adds the `-ta=nvidia:maxregcount:n` switch to the PVF compilation and link lines.

Leaving this property blank indicates no limit to the number of registers to use on the GPU.

NVIDIA: Use Fused Multiply-Adds

When Target NVIDIA Accelerator is set to *Yes*, use this property to control the generation of fused multiply-add (FMA) instructions.

Setting this property to *Yes* enables generation of FMA instructions; this is the default.

Setting this property to *No* adds the `-ta=nvidia:nofma` switch to compilation and linking.

NVIDIA: Use Fast Math Library

When Target NVIDIA Accelerator is set to *Yes*, use this property to use routines from the fast math library.

Setting this property to *Yes* adds the `-ta=nvidia:fastmath` switch to compilation and linking.

NVIDIA: Flush to Zero

When Target NVIDIA Accelerator is set to *Yes*, use this property to control flush-to-zero mode for floating point computations in the GPU code generated for PGI Accelerator model compute regions.

- **Default:** Accepts the default handling of floating point computations in the GPU code generated for CUDA Fortran kernels.
- **Yes:** Enables flush-to-zero mode by adding the `-ta=nvidia: flushz` switch to the PVF compilation and link lines.
- **No:** Disables flush-to-zero mode by adding the `-ta=nvidia:noflushz` switch to the PVF compilation and link lines.

NVIDIA: Use 24-bit Subscript Multiplication

When Target NVIDIA Accelerator is set to `Yes`, use this property to use 24-bit multiplication for subscripting.

Setting this property to `Yes` adds the `-ta=nvidia:mul24` switch to compilation and linking.

NVIDIA: Synchronous Kernel Launch

When Target NVIDIA Accelerator is set to `Yes`, use this property to wait for each kernel to finish before continuing in the host program.

Setting this property to `Yes` adds the `-ta=nvidia:wait` switch to compilation and linking and overrides the `nowait` clause. This is the default.

Setting this property to `No` adds the `-ta=nvidia:nowait` switch to compilation and linking.

NVIDIA: CUDA Toolkit

When Target NVIDIA Accelerator is set to `Yes`, use this property to specify the version of the NVIDIA CUDA toolkit that is targeted by the compilers:

- **Default:** The compiler selects the default CUDA toolkit version.
- **2.3:** Use version 2.3 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda2.3` switch to the PVF compilation and link lines.
- **3.0:** Use version 3.0 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda3.0` switch to the PVF compilation and link lines.
- **3.1:** Use version 3.1 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda3.1` switch to the PVF compilation and link lines.
- **3.2:** Use version 3.2 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda3.2` switch to the PVF compilation and link lines.
- **4.0:** Use version 4.0 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda4.0` switch to the PVF compilation and link lines.
- **4.1:** Use the default version 4.1 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda4.1` switch to the PVF compilation and link lines.
- **4.2:** Use version 4.2 of the CUDA toolkit. This selection adds the `-ta=nvidia:cuda4.2` switch to the PVF compilation and link lines.

Note

Compiling with the CUDA 3.1 or higher toolkit, either by setting the appropriate property as just described or by adding `set CUDAVERSION=3.1`, `set CUDAVERSION=3.2`, `set CUDAVERSION=4.0`, `set CUDAVERSION=4.1`, or `set CUDAVERSION=4.2` to the `siterc` file, generates binaries that may not work on machines with a 2.3 CUDA driver.

`pgaccelinfo` prints the driver version as the first line of output.

For a 2.3 driver: CUDA Driver Version 2030
 For a 3.0 driver: CUDA Driver Version 3000
 For a 3.1 driver: CUDA Driver Version 3010
 For a 3.2 driver: CUDA Driver Version 3020
 For a 4.0 driver: CUDA Driver Version 4000
 For a 4.1 driver: CUDA Driver Version 4010
 For a 4.2 driver: CUDA Driver Version 4020

For more information on `-ta=nvidia`, refer to [-ta](#).

NVIDIA: Compute Capability

When Target NVIDIA Accelerator is set to `Yes`, use this property to either automatically generate code compatible with all applicable compute capabilities, or to direct the compiler to use a manually-selected set.

Select either `Automatic` or `Manual`.

- **Automatic:** Let the compiler generate code for all applicable compute capabilities. This is the default.
- **Manual:** Choose one or more compute capabilities to target. The compiler generates code for each capability specified.

If you select `Manual`, then you can select any or all of the following compute capabilities that are described in the next sections.

[NVIDIA: CC 1.0](#)

[NVIDIA: CC 1.1](#)

[NVIDIA: CC 1.2](#)

[NVIDIA: CC 1.3](#)

[NVIDIA: CC 3.0](#)

Important

If you select `Manual` and the additional properties do not appear, click `Apply` in the Property page dialog.

For more information on `-ta=nvidia`, refer to “[-ta=nvidia\(,nvidia_suboptions\),host,](#)” on page 39.

NVIDIA: CC 1.0

When Target NVIDIA Accelerator is set to `Yes` and NVIDIA Compute Capability is set to `Manual`, use this property to generate code for NVIDIA compute capability 1.0.

Setting this property to `Yes` adds the `-ta=nvidia:cc10` switch to the PVF compilation and link lines.

NVIDIA: CC 1.1

When Target NVIDIA Accelerator is set to `Yes` and NVIDIA Compute Capability is set to `Manual`, use this property to generate code for NVIDIA compute capability 1.1.

Setting this property to `Yes` adds the `-ta=nvidia:cc11` switch to the PVF compilation and link lines.

NVIDIA: CC 1.2

When Target NVIDIA Accelerator is set to `Yes` and NVIDIA Compute Capability is set to `Manual`, use this property to generate code for NVIDIA compute capability 1.2.

Setting this property to `Yes` adds the `-ta=nvidia:cc12` switch to the PVF compilation and link lines.

NVIDIA: CC 1.3

When Target NVIDIA Accelerator is set to `Yes` and NVIDIA Compute Capability is set to `Manual`, use this property to generate code for NVIDIA compute capability 1.3.

Setting this property to `Yes` adds the `-ta=nvidia:cc13` switch to the PVF compilation and link lines.

NVIDIA: CC 2.0

When Target NVIDIA Accelerator is set to `Yes` and NVIDIA Compute Capability is set to `Manual`, use this property to generate code for NVIDIA compute capability 2.0.

Setting this property to `Yes` adds the `-ta=nvidia:cc20` switch to the PVF compilation and link lines.

NVIDIA: CC 3.0

When Target NVIDIA Accelerator is set to `Yes` and NVIDIA Compute Capability is set to `Manual`, use this property to generate code for NVIDIA compute capability 3.0.

Setting this property to `Yes` adds the `-ta=nvidia:cc30` switch to the PVF compilation and link lines.

NVIDIA: Keep Kernel Binary

When Target NVIDIA Accelerator is set to `Yes`, use this property to keep kernel binary (.bin) files.

Setting this property to `Yes` adds the `-ta=nvidia:keepbin` switch to compilation and linking.

NVIDIA: Keep Kernel Source

When Target NVIDIA Accelerator is set to `Yes`, use this property to keep kernel source files.

Setting this property to `Yes` adds the `-ta=nvidia:keepgpu` switch to compilation and linking.

NVIDIA: Keep Kernel PTX

When Target NVIDIA Accelerator is set to `Yes`, use this property to keep the portable assembly (.ptx) file for the GPU code.

Setting this property to `Yes` adds the `-ta=nvidia:keepptx` switch to compilation and linking.

NVIDIA: Enable Profiling

When Target NVIDIA Accelerator is set to `Yes`, use this property to collect simple timing information for accelerator kernel profiling.

Setting this property to `Yes` adds the `-ta=nvidia:time` switch to compilation and linking.

NVIDIA: Analysis Only

When Target NVIDIA Accelerator is set to `Yes`, use this property to perform loop analysis only; the compiler does not generate GPU code.

Setting this property to `Yes` adds the `-ta=nvidia:analysis` switch to compilation and linking.

Target Host

Use this property to generate code just for the host if no accelerator is selected. Otherwise, generate PGI Unified Binary Code for host and accelerator.

Setting this property to `Yes` adds the `-ta=host` switch to compilation and linking.

Fortran | Diagnostics

The following properties are available from the Fortran | Diagnostics property page. These properties allow you to add switches to the compilation line that control the amount and type of information that the compiler provides.

For more information on the options referenced in these pages, refer to [“Miscellaneous Controls,” on page 70](#) and [–Minfo](#).

Warning Level

Use this property to select the level of diagnostic reporting you want the compiler to use.

There are several levels of the `-Minform` option available through this property. For more information on this option, refer to [“Miscellaneous Controls,” on page 70](#).

Generate Assembly

Use this property to generate an assembly file for each compiled source file.

Setting this property to `Yes` adds the `-Mkeepasm` switch to the compilation line.

For more information on `-Mkeepasm`, refer to [“Miscellaneous Controls,” on page 70](#).

Annotate Assembly

Use this property to generate assembly files and to annotate the assembly with source code.

Setting this property to `Yes` adds the `-Manno` switch to the compilation line.

For more information on `-Manno`, refer to [“Miscellaneous Controls,” on page 70](#).

Accelerator Information

Use this property to generate information about accelerator regions.

Setting this property to `Yes` adds the `-Minfo=accel` switch to the compilation line.

CCFF Information

Use this property to append common compiler feedback format (CCFF) information to object files.

Setting this property to `Yes` adds the `-Minfo=ccff` switch to the compilation line.

Fortran Language Information

Use this property to generate information about Fortran language features.

Setting this property to `Yes` adds the `-Minfo=ftn` switch to the compilation line.

Inlining Information

Use this property to generate information about inlining.

Setting this property to `Yes` adds the `-Minfo=inline` switch to the compilation line.

IPA Information

Use this property to generate information about interprocedural analysis (IPA) optimizations.

Setting this property to `Yes` adds the `-Minfo=ipa` switch to the compilation line.

Loop Intensity Information

Use this property to generate compute intensity information about loops.

Setting this property to `Yes` adds the `-Minfo=intensity` switch to the compilation line.

Loop Optimization Information

Use this property to generate information about loop optimizations.

Setting this property to `Yes` adds the `-Minfo=loop` switch to the compilation line.

LRE Information

Use this property to generate information about loop-carried redundancy (LRE) elimination.

Setting this property to `Yes` adds the `-Minfo=lre` switch to the compilation line.

OpenMP Information

Use this property to generate information about OpenMP.

Setting this property to `Yes` adds the `-Minfo=mp` switch to the compilation line.

Optimization Information

Use this property to generate information about general optimizations.

Setting this property to `Yes` adds the `-Minfo=opt` switch to the compilation line.

Parallelization Information

Use this property to generate information about parallel optimizations.

Setting this property to `Yes` adds the `-Minfo=par` switch to the compilation line.

Unified Binary Information

Use this property to generate information specific to the PGI Unified Binary.

Setting this property to `Yes` adds the `-Minfo=unified` switch to the compilation line.

Vectorization Information

Use this property to generate vectorization information.

Setting this property to `Yes` adds the `-Minfo=vect` switch to the compilation line.

Fortran | Profiling

The following properties are available from the Fortran | Profiling property page so a run can be profiled with the PGI profiler, *PGPROF*.

Once your application is built, running it generates one or more `pgprof.out` files.

PGPROF is included with PVF. You launch it from the PVF start menu via *Start | All Programs | PGI Visual Fortran | Profiler | PGPROF Performance Profiler*.

For specific *PGPROF* documentation, launch *PGPROF* and open the documentation available from the *PGPROF* Help menu.

For more information on the `-Mprof` option, refer to [“Code Generation Controls,” on page 49](#).

Function-Level Profiling

Use this property to generate code instrumented for function-level profiling.

Setting this property to `Yes` adds the `-Mprof=func` switch to the compiling and linking lines.

Line-Level Profiling

Use this property to generate code instrumented for line-level profiling.

Setting this property to `Yes` adds the `-Mprof=lines` switch to the compiling and linking lines.

MPI

Use this property to access profiled MPI communication libraries.

Note

You must use this property in conjunction with function-level or line-level profiling. Be certain to set one of these properties to `Yes`.

Setting this property to `Microsoft MPI` adds the `-Mprof=msmpi` switch to the PVF compiling and linking lines.

Suppress CCFF Information

Use this property to suppress profiling's default generation of CCFF information.

Setting this property to `Yes` adds the `-Mprof=nocff` switch to the compiling and linking lines.

Enable Limited DWARF

Use this property to generate limited DWARF information which can be used with performance profilers.

Setting this property to `Yes` adds the `-Mprof=dwarf` switch to the compiling and linking lines.

Fortran | Runtime

The following properties are available from the Fortran | Runtime property page to allow the application to make additional checks at runtime.

Check Array Bounds

Use this property to enable array bounds checking at runtime.

Setting this property to `Yes` adds the `-Mbounds` switch to the compilation line.

Setting this property to `No` adds no option to the compilation line, and there is no array bounds checking at runtime. `No` is the default.

Check Pointers

Use this property to perform runtime checks for pointers that are dereferenced while initialized to null.

Setting this property to `Yes` adds the `-Mchkptr` switch to the compilation line.

Setting this property to `No` adds no option to the compilation line, and there is no runtime check for pointers that are dereferenced while initialized to null. `No` is the default.

Check Stack

Use this property to perform runtime stack checks for available space in the prologue of a function and before the start of a parallel region.

Setting this property to `Yes` adds the `-Mchkstk` switch to the compilation line.

Setting this property to `No` adds no option to the compilation line, and there are no runtime stack checks. `No` is the default.

Command Line

This property page contains two boxes.

- The first box, titled *All options*, is a read-only description of what the compilation line will be. This description is based on the values of the properties set in the Fortran property pages.
- The second box, titled *Additional options*, allows you to specify any other options that you want the compiler to use. Use this box when the option you need is not available through any of the Fortran property pages.

For more information on all the compiler options that are available, refer to [Chapter 2, “Command-Line Options Reference,”](#) on page 5.

Fortran | Command Line

The following properties are available from the Fortran | Command Line property page.

Command Line

This property page contains two boxes.

- The first box, titled *All options*, is a read-only description of what the compilation line will be. This description is based on the values of the properties set in the Fortran property pages.
- The second box, titled *Additional options*, allows you to specify any other options that you want the compiler to use. Use this box when the option you need is not available through any of the Fortran property pages.

For more information on all the compiler options that are available, refer to [Chapter 2, “Command-Line Options Reference,”](#) on page 5.

Linker Property Pages

This section contains the property pages that are included in the Linker category. The Linker property page category is available for projects that build an executable or a dynamically linked library (DLL).

Linker | General

The following properties are available from the Linker | General property page.

Output File

Use this property to override the default output file name.

Providing the file name and the file’s extension is equivalent to using the `-o` switch.

Note

You must provide the file’s extension.

For more information on `-o`, refer to [“-o,”](#) on page 33.

Additional Library Directories

Use this property to add one or more directories to the library search path.

For every directory path that is added to this property, PVF adds `/LIBPATH: [dir]` to the link line.

There are two ways to add directories to this property:

- Type the information directly into the property page box.

Use a semi-colon (‘;’) to separate each directory.

- Click the ellipsis (‘...’) button in the property page box to open the *Additional Library Directories* dialog box.

Enter each directory on its own line in this box. Do not use semi-colons to separate directories; the semi-colons are added automatically when the box is closed.

Tip

To add directories, use this property. To add libraries, use the *Additional Dependencies* property on the Linker | Input property page.

Stack Reserve Size

Use this property to specify the total number of bytes for stack allocation in virtual memory. Use decimal notation. This property is equivalent to the `-stack=reserve` option. Leave this property blank to direct the linker to choose a default size for the stack.

Stack Commit Size

Use this property to specify the total number of bytes for stack allocation in physical memory. Use decimal notation. This property is equivalent to the `-stack=reserve, commit` option. Commit Size is used only if a size is also specified for Stack Reserve.

Export Symbols

Use this property to specify whether the DLL will export symbols. This property is only visible for DLL project types.

Linker | Input

The following properties are available from the Linker | Input property page.

Additional Dependencies

Use this property to specify additional dependencies, such as libraries, to the link line.

There are two ways to add libraries to this property:

- Type the information directly into the property page box.

Note

Use spaces, not semi-colons, to separate multiple libraries. If the name of a library contains a space, use double quotes around that library name.

- Click the ellipsis ('...') button in the property page box to open the *Additional Dependencies* dialog box.

Enter each library on its own line in this box.

Note

If you enter two libraries on the same line in this box, PVF interprets these as a single library whose name contains spaces.

Tip

When you close this dialog box, review the contents of the property to make sure that any spaces or double quotes automatically added by PVF are appropriate for your project.

Linker | Command Line

The following properties are available from the Linker | Command Line property page.

Command Line

This property page contains two boxes.

- The first box, titled *All options*, is a read-only description of what the link line will be. This value is based on the values of the properties set in the Linker property pages.
- The second box, titled *Additional options* allows you to specify options that you want the linker to use. Use this box when the option you need is not available through any of the Linker property pages.

For more information on all the compiler options that are available, refer to [Chapter 2, “Command-Line Options Reference,” on page 5](#).

Librarian Property Pages

This section contains the property pages that are included in the Librarian category. The Librarian property pages are available for projects that build static libraries.

Librarian | General

The following properties are available from the Librarian | General property page.

Output File

Use this property to override the default output file name.

Providing the file name and the file's extension is equivalent to using the `-o` switch.

Note

You must provide the file's extension.

For more information on `-o`, refer to [“-o,” on page 33](#).

Additional Library Directories

Use this property to add one or more directories to the library search path.

For every directory path that is added to this property, PVF adds `/LIBPATH:<dir>` to the link line.

There are two ways to add directories to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each directory.

- Click the ellipsis (...) button in the property page box to open the *Additional Library Directories* dialog box.

Enter each directory on its own line in this box. Do not use semi-colons to separate directories; the semi-colons are added automatically when the box is closed.

Tip

To add directories, use this property. To add libraries, use the Additional Dependencies property.

Additional Dependencies

Use this property to specify additional dependencies, such as libraries, to the link line.

There are two ways to add libraries to this property:

- Type the information directly into the property page box.

Note

Use spaces, not semi-colons, to separate multiple libraries. If the name of a library contains a space, use double quotes around that library name.

- Click the ellipsis (...) button in the property page box to open the *Additional Dependencies* dialog box.

Enter each library on its own line in this box.

Note

If you enter two libraries on the same line in this box, PVF interprets these as a single library whose name contains spaces.

Tip

When you close this dialog box, review the contents of the property to make sure that any spaces or double quotes automatically added by PVF are appropriate for your project.

Librarian | Command Line

The following properties are available from the Librarian | Command Line property page.

Command Line

This property page contains two boxes.

- The first box, titled *All options*, is a read-only description of what the link line will be. This value is based on the values of the properties set in the Librarian property pages.
- The second box, titled *Additional options*, allows you to specify options that you want the librarian to use, even though these options are not available through any of the Librarian property pages.

For more information on all the compiler options that are available, refer to [Chapter 2, “*Command-Line Options Reference*,” on page 5](#).

Resources Property Page

This section contains the property pages that are included in the Resources category.

Resources | Command Line

The following properties are available from the Resources | Command Line property page.

Command Line

Use this property to add options to the Resource compiler’s command line.

PVF’s support of resources is somewhat limited at this time and the property pages in this category reflect that. To add options to the Resource compiler’s command line, use the *Additional options* box on this property page.

Build Events Property Page

This section contains the property pages that are included in the Build Events category. Build events include three types of events: Pre-Build, Pre-Link, and Post-Build.

The Build Events property pages provide an opportunity to specify actions, in addition to compiling and linking, that you want to have happen during the process of a build.

Build Event

The name of the build event describes when the event will be fired.

- The Pre-Build Event is run before a build starts.
- The Pre-Link Event is run after compilation but before linking.
- The Post-Build Event is run after the build completes.

Note

Build events will not be run if a project is up-to-date.

The properties for a build event are the same for all three types of build events.

Command Line

Use this property to specify the command line that the build tool will run.

This property is at the core of the build event. For example, to add a time stamp to a build, you could use `time /t` as the build event's command line.

Description

Use this property to provide feedback to the Output window. The contents of the Description property is echoed to the Output window when this event is fired.

Excluded From Build

Use this property to specify whether this build event should be excluded from the build for the current configuration.

Custom Build Step Property Page

This section contains the property pages that are included in the Custom Build Step category.

You can define a custom build step either for a project or for an individual file. Custom build steps can only be defined for files that are not Fortran or resource files.

Custom Build Step | General

The following properties are available from the Custom Build Step | General property page.

Command Line

Use this property to specify the command line that the build tool will run. This property is at the core of the custom build step.

Description

Use this property to provide feedback to the Output window. The contents of the Description property is echoed to the Output window when the custom build step runs.

Outputs

Use this property to specify the files generated by the custom build step.

Use semi-colons (';') to separate multiple output files.

Note

When a custom build step is specified at the file-level, this property must be non-empty or the custom build step will be skipped.

Additional Dependencies

Use this property to specify any additional input files to use for the custom build.

Note

The custom build step is run when an additional dependency is out of date.

There are two ways to add files to this property:

- Type the information directly into the property page box.

Use a semi-colon (;) to separate each directory.

- Click the ellipsis (...) button in the property page box to open the *Additional Dependencies* dialog box.

Enter each file on its own line in this box. Do not use semi-colons to separate directories; the semi-colons are added automatically when the box is closed.

Chapter 8. PVF Build Macros

PVF implements a subset of the build macros supported by Visual C++ along with a few PVF-specific macros. The macro names are not case-sensitive, and they should be usable in any string field in a property page. Unless otherwise noted, macros that evaluate to directory names end with a trailing backslash ('\').

In general these items can only be changed if there is an associated PVF project or file property. For example, \$(VCInstallDir) cannot be changed, while \$(IntDir) can be changed by modifying the General Intermediate Directory property.

[Table 8.1](#) lists the build macros that PVF supports:

Table 8.1. PVF Build Macros

Macro Name	Description
\$(Configuration)	The name of the current project configuration (for example, "Debug").
\$(ConfigurationName)	The name of the current project configuration (for example, "Debug").
\$(ConfigurationType)	The type of the current project configuration - one of the following: "Application" "StaticLibrary" "DynamicLibrary"
\$(DevEnvDir)	The installation directory of Visual Studio.
\$(InputDir)	The directory of the input file. If the project is the input, then this macro is equivalent to \$(ProjectDir).
\$(InputExt)	The file extension of the input file, including the '.' before the file extension. If the project is the input, then this macro is equivalent to \$(ProjectExt).
\$(InputFileName)	The file name of the input file. If the project is the input, then this macro is equivalent to \$(ProjectFileName).
\$(InputName)	The base name of the input file. If the project is the input, then this macro is equivalent to \$(ProjectName).
\$(InputPath)	The full path name of the input file. If the project is the input, then this macro is equivalent to \$(ProjectPath).

Macro Name	Description
\$(IntDir)	The path to the directory for intermediate files, relative to the project directory, as set by the Intermediate Directory property.
\$(OpenToolsDir)	[PVF only]. The location of the Open Tools installation directory, including files needed for building Microsoft Windows applications for both 32-bit and 64-bit environments.
\$(OutDir)	The path to the directory for output files, relative to the project directory, as set by the Output Directory property.
\$(OutputPath)	The path to the directory for output files, relative to the project directory, as set by the Output Directory property.
\$(OutputType)	The type of the current project output - one of the following: “exe” “staticlibrary” “library”
\$(PGITools32Dir)	[PVF only]. The location of the active PGI toolset for 32-bit targets. This directory is the parent of <code>bin</code> , <code>lib</code> , and <code>include</code> directories containing executables, libraries, and include files for the PGI development environment.
\$(PGIToolsDir)	[PVF only]. The location of the active PGI toolset for 64-bit targets. This directory is the parent of <code>bin</code> , <code>lib</code> , and <code>include</code> directories containing executables, libraries, and include files for the PGI development environment.
\$(Platform)	The name of the current project platform (for example, "x64").
\$(PlatformArchitecture)	The name of the current project platform architecture. For Win32: 32 For x64: 64
\$(PlatformName)	The name of the current project platform (for example, "x64").
\$(PlatformShortName)	The description of the architecture ABI for the current project platform. For Win32: x86 For x64: amd64
\$(ProjectDir)	The directory of the project.
\$(ProjectExt)	The file extension of the project file, including the ‘.’ before the file extension.
\$(ProjectFileName)	The file name of the project file.
\$(ProjectName)	The base name of the project.
\$(ProjectPath)	The full path name of the project.
\$(SolutionDir)	The directory of the solution.
\$(SolutionExt)	The file extension of the solution file, including the ‘.’ before the file extension.

Macro Name	Description
<code>\$(SolutionFileName)</code>	The file name of the solution file.
<code>\$(SolutionName)</code>	The base name of the solution.
<code>\$(SolutionPath)</code>	The full path name of the solution.
<code>\$(TargetDir)</code>	The directory of the primary output file of the build.
<code>\$(TargetExt)</code>	The file extension of the primary output file of the build, including the '.' before the file extension.
<code>\$(TargetFileName)</code>	The file name of the primary output file of the build.
<code>\$(TargetPath)</code>	The full path name of the primary output file of the build.
<code>\$(VCInstallDir)</code>	The Visual C++ installation directory. If Visual C++ is not installed, this macro may evaluate to a directory that does not exist.
<code>\$(VSInstallDir)</code>	The Visual Studio installation directory.

Chapter 9. Fortran Module/Library Interfaces for Windows

PGI Visual Fortran provides access to a number of libraries that export C interfaces by using Fortran modules. PVF uses this mechanism to support the Win32 API and Unix/Linux portability libraries. This chapter describes the Fortran module library interfaces that PVF supports, describing each property available.

Source Files

All routines described in this chapter have their prototypes and interfaces described in source files that are included in the PGI Windows compiler installation. The location of these files depends on your operating system version, either win32 or win64, and the release version that you have installed, such as 7.2-5 or 10.0-0. These files are typically located in this directory:

```
C:/Program Files/PGI/{win32,win64}/[release_version]/src
```

For example, if you have installed the Win32 version of the 11.0-0 release, look for your files in this location:

```
C:/Program Files/PGI/win32/11.0-0/src
```

Data Types

Because the Win32 API and Portability interfaces resolve to C language libraries, it is important to understand how the data types compare within the two languages. Here is a table summarizing how C types correspond with Fortran types for some of the more common data types:

Table 9.1. Fortran Data Type Mappings

Windows Data Type	Fortran Data Type
BOOL	LOGICAL(4)
BYTE	BYTE
CHAR	CHARACTER
SHORT, WORD	INTEGER(2)
DWORD, INT, LONG	INTEGER(4)

Windows Data Type	Fortran Data Type
LONG LONG	INTEGER(8)
FLOAT	REAL(4)
DOUBLE	REAL(8)
x86 Pointers	INTEGER(4)
x64 Pointers	INTEGER(8)

For more information on data types, refer to [“Fortran Data Types,” on page 1](#).

Using DFLIB, LIBM, and DFPORT

PVF includes Fortran module interfaces to libraries supporting some standard C library, C math library, and Unix/Linux system call functionality. These functions are provided by the `DFLIB`, `LIBM`, and `DFPORT` modules. To utilize these modules, add the appropriate `USE` statement:

```
use dflib
```

```
use libm
```

```
use dfport
```

DFLIB

[Table 9.2](#) lists the functions that `DFLIB` includes. In the table `[Generic]` refers to a generic routine. To view the prototype and interfaces, look in the location described in [“Source Files,” on page 221](#).

Table 9.2. DFLIB Function Summary

Routine	Result	Description
<code>commitqq</code>	LOGICAL*4	Executes any pending write operations for the file associated with the specified unit to the file's physical device.
<code>delfilesqq</code>	INTEGER*4	Deletes the specified files in a specified directory.
<code>findfileqq</code>	INTEGER*4	Searches for a file in the directories specified in the <code>PATH</code> environment variable.
<code>fullpathqq</code>	INTEGER*4	Returns the full path for a specified file or directory.
<code>getdat</code>	INTEGER*2,*4,*8	[Generic] Returns the date.
<code>getdrivedirqq</code>	INTEGER*4	Returns the current drive and directory path.
<code>getenvqq</code>	INTEGER*4	Returns a value from the current environment.
<code>getfileinfoqq</code>	INTEGER*4	Returns information about files with names that match the specified string.
<code>getfileinfoqqi8</code>	INTEGER*4	Returns information about files with names that match the specified string.
<code>gettim</code>	INTEGER*2,*4,*8	[Generic] Returns the time.
<code>makedirqq</code>	INTEGER*4	Creates a new directory.

Routine	Result	Description
packtimeqq	INTEGER*4	Packs the time and date values for use by setfiletimeqq
renamefileqq	LOGICAL*4	Renames the specified file.
runqq	INTEGER*2	Calls another program and waits for it to execute.
setenvqq	LOGICAL*4	Sets the values of an existing environment variable or adds a new one.
setfileaccessqq	LOGICAL*4	Sets the file access mode for the specified file.
setfiletimeqq	LOGICAL*4	Sets the modification time for the specified file.
signalqq	INTEGER*8	Controls signal handling.
sleepqq	None	Delays execution of the program for a specified time.
splitpathqq	LOGICAL*4	Breaks a full path into components.
systemqq	LOGICAL*4	Executes a command by passing a command string to the operating system's command interpreter.
unpacktimeqq	Multiple INTEGERS	Unpacks a file's packed time and date value into its component parts.

LIBM

A Fortran module is available to declare interfaces to many of the routines in the standard C math library: `libm`. [Table 9.3](#) lists the `LIBM` routines that are available. To view the prototype and interfaces, look in the location described in “[Source Files](#),” on [page 221](#).

Some `libm` routine names conflict with Fortran intrinsics. These routines are not listed in this table because they resolve to Fortran intrinsics.

asin	acos	atan2	cos	cosh
exp	log	log10	sin	sinh
sqrt	tan	tanh		

You can also use `libm` routines in CUDA Fortran global and device subprograms, in CUF kernels, and in PGI Accelerator compute regions. When targeting NVIDIA devices, the `libm` routines translate to the corresponding `libm` device routine.

Table 9.3. LIBM Functions

acosf	erfc	frexp	log1p	remquo
acosh	erff	frexpf	log1pf	remquof
acoshf	erfcf	ilog	log2	rint
asinf	expf	ilogbf	log2f	rintf
asinh	exp10	ldexp	logb	scalbn
asinhf	exp10f	ldexpf	logbf	scalbnf
atan2f	exp2	lgamma	logf	scalbln

atanh	exp2f	lgammaf	modf	scalblnf
atanhf	expf	llrint	modff	sinf
cbrt	expm1	llrintf	nearbyint	sinhf
cbrtf	expm1f	lrint	nearbyintf	sqrtf
ceil	floor	lrint	nextafter	tanf
ceilf	floorf	llround	nextafterf	tanhf
copysign	fma	llroundf	pow	tgamma
copysignf	fmaf	lround	powf	tgammaf
cosf	fmax	lroundf	remainder	trunc
coshf	fmaxf	log10f	remainderf	truncf
erf	fminf			

DFPORT

Table 9.4 lists the functions that DFPORT includes. In the table [Generic] refers to a generic routine. To view the prototype and interfaces, look in the location described in “Source Files,” on page 221.

Table 9.4. DFPORT Functions

Routine	Result	Description
abort	None	Immediately terminates the program. If the operating systems supports a core dump, abort produces one that can be used for debugging.
access	INTEGER*4	Determines access mode or existence of a file.
alarm	INTEGER*4	Executes a routine after a specified time.
besj0	REAL*4	Computes the BESSEL function of the first kind of order 0 of X, where X is real.
besj1	REAL*4	Computes the BESSEL function of the first kind of order 1 of X, where X is real.
besjn	REAL*4	Computes the BESSEL function of the first kind of order N of X, where N is an integer and X is real.
besy0	REAL*4	Computes the BESSEL function of the second kind of order 0 of X, where X is real.
besy1	REAL*4	Computes the BESSEL function of the second kind of order 1 of X, where X is real.
besyn	REAL*4	Computes the BESSEL function of the second kind of order N of X, where N is an integer and X is real.
chdir	INTEGER*4	Changes the current directory to the directory specified. Returns 0, if successful or an error

Routine	Result	Description
chmod	INTEGER*4	Changes the mode of a file by setting the access permissions of the specified file to the specified mode. Returns 0 if successful, or error
ctime	STRING(24)	Converts and returns the specified time and date as a string.
date	STRING	Returns the date as a character string: dd-mm-yy.
dbesj0	REAL*8	Computes the double-precision BESSEL function of the first kind of order 0 of X, where X is a double-precision argument.
dbesj1	REAL*8	Computes the double-precision BESSEL function of the first kind of order 1 of X, where X is a double-precision argument.
dbesjn	REAL*8	Computes the double-precision BESSEL function of the first kind of order N of X, where N is an integer and X is a double-precision argument.
dbesy0	REAL*8	Computes the double-precision BESSEL function of the second kind of order 0 of X, where X, where X is a double-precision argument.
dbesy1	REAL*8	Computes the double-precision BESSEL function of the second kind of order 1 of X, where X, where X is a double-precision argument.
dbesyn	REAL*8	Computes the double-precision BESSEL function of the second kind of order N of X, where N is an integer and X, where X is a double-precision argument.
derf	REAL*8	Computes the double-precision error function of X, where X is a double-precision argument.
derfc	REAL*8	Computes the complementary double-precision error function of X, where X is a double-precision argument.
dfrac	REAL*8	Returns fractional accuracy of a REAL*8 floating-point value.
dflmax	REAL*8	Returns the maximum positive REAL*8 floating-point value.
dflmin	REAL*8	Returns the minimum positive REAL*8 floating-point value.
drandm	REAL*8	Generates a REAL*8 random number.
dsecnds	REAL*8	Returns the number of real time seconds since midnight minus the supplied argument value.
dtime	REAL*4	Returns the elapsed user and system time in seconds since the last call to dtime.
erf	REAL*4	Computes the error function of X, where X is Real.

Routine	Result	Description
erfc	REAL	Computes the complementary error function of X, where X is Real.
etime	REAL*4	Returns the elapsed time in seconds since the start of program execution.
exit	None	Immediately terminates the program and passes a status to the parent process.
fdate	STRING	Returns the current date and time as an ASCII string.
ffrac	REAL*4	Returns the fractional accuracy of a REAL*4 floating-point value.
fgetc	INTEGER*4	Gets a character or word from an input stream. Returns the next byte or and integer
flmax	REAL*4	Returns the maximum positive REAL*4 floating-point value.
flmin	REAL*4	Returns the minimum positive REAL*4 floating-point value.
flush	None	Writes the output to a logical unit.
fputc	INTEGER*4	Writes a character or word from an input stream to a logical unit. Returns 0 if successful or an error.
free	None	Frees memory previously allocated by MALLOC(). Intended for users compiling legacy code. Use DEALLOCATE for newer code.
fseek	INTEGER*4	Repositions the file pointer associated with the specified file. Returns 0 if successful, 1 otherwise.
fseek64	INTEGER*4	Repositions the file pointer associated with the specified stream. Returns 0 if successful, 1 otherwise.
fstat	INTEGER*4	Returns file status information about the referenced open file or shared memory object.
fstat64	INTEGER*4	Returns information in a 64-bit structure about the referenced open file or shared memory object.
ftell	INTEGER*4	Returns the current value of the file pointer associated with the specified stream.
ftell64	INTEGER*8	Returns the current value of the file pointer associated with the specified stream.
gerror	STRING	Writes system error messages.
getarg	STRING	Returns the list of parameters that were passed to the current process when it was started.
getc	INTEGER*4	Retrieves the character at the front of the specified character list, or -1 if empty
getcwd	INTEGER*4	Retrieves the pathname of the current working directory or null if fails.

Routine	Result	Description
getenv		Returns the value of the specified environment variable(s).
getfd	INTEGER*4	Returns the file descriptor associated with a Fortran logical unit.
getgid	INTEGER*4	Returns the numerical group ID of the current process.
getlog	STRING	Stores the user's login name in NAME. If the login name is not found, then NAME is filled with blanks.
getpid	INTEGER*4	Returns the process numerical identifier of the current process.
getuid	INTEGER*4	Returns the numerical user ID of the current process.
gmtime	INTEGER*4	Converts and returns the date and time formats to GM (Greenwich) time as month, day, and so on.
hostnm	INTEGER*4	Sets or Gets the name of the current host. If setting the hostname, returns 0 if successful, errno if not.
iargc	INTEGER*4	Returns an integer representing the number of arguments for the last program entered on the command line.
idate	INTEGER*4	Returns the date in numerical form, day, month, year.
ierrno	INTEGER*4	Returns the system error number for the last error.
inmax	INTEGER*4	Returns the maximum positive integer value.
ioinit	None	Establishes the properties of file I/O for files opened after the call to ioinit, such as whether to recognize carriage control, how to treat blanks and zeros, and whether to open files at the beginning or end of the file.
irand1	INTEGER*4	Generates pseudo-random integer in the range of 0 through (2**31)-1, or (2**15)-1 if called with no argument.
irand2	INTEGER*4	Generates pseudo-random integer in the range of 0 through (2**31)-1, or (2**15)-1 if called with no argument.
irandm	INTEGER*4	Generates pseudo-random integer in the range of 0 through (2**31)-1, or (2**15)-1 if called with no argument.
isatty	LOGICAL	Finds the name of a terminal port. Returns TRUE if the specified unit is a terminal.
itime	numerical form of time	Fills and returns TARRAY with numerical values at the current local time, with elements 1,2,and 3 of TARRY being the hour (1-24), minute (1-60) and seconds (1-60).
kill	INTEGER*4	Sends the specified signal to the specified process or group of processes. Returns 0 if successful, -1 otherwise
link	INTEGER*4	Creates an additional directory entry for the specified existing file.

Routine	Result	Description
lnblnk	INTEGER*4	Returns the position of the last non-blank string character in the specified string.
loc	INTEGER*4	Returns the address of an object.
long	INTEGER*4	Converts INTEGER*2 to INTEGER*4
lstat	INTEGER*4	Obtains information about the referenced open file or shared memory object in a large-file enables programming environment.
lstat64	INTEGER*4	Obtains information in a 64-bit structure about the referenced open file or shared memory object in a large-file enables programming environment.
ltime	Array of INTEGER*4	Converts the system time from seconds into TARRAY, which contains GMT for the current local time zone.
malloc	INTEGER*8	Allocates SIZE bytes of dynamic memory, returning the address of the allocated memory. Intended for users compiling legacy code. Use ALLOCATE for newer code.
mclock	INTEGER*4	Returns time accounting information about the current process and its child processes in 1/100 or second units of measure. The returned value is the sum of the current process's user time and system time of all child processes.
outstr	INTEGER*4	Outputs the value of the specified character to the standard output file.
perror	None	Writes a message to standard error output that describes the last error encountered by a system call or library subroutine.
putc	INTEGER*4	Puts the specified character at the end of the character list.
putenv	INTEGER*4	Sets the value of the specified environment variable or creates a new environment variable.
qsort	INTEGER*4	Uses quick-sort algorithm to sort a table of data.
rand1	REAL*4	Provides a method for generating a random number that can be used as the starting point for the rand procedure.
rand2	REAL*4	Provides a random value between 0 and 1, which is generated using the specified seed value, and computed for each returned row when used in the select list.
random	REAL*4	Uses a non-linear additive feedback random-number generator to return pseudo-random numbers in the range of 0 to $(2^{31}-1)$
rename	INTEGER*4	Renames the specified directory or file

Routine	Result	Description
<code>rindex</code>	INTEGER*4	Returns the index of the last occurrence of a specific string of characters in a specified string.
<code>rtc</code>	REAL*8	Returns the real-time clock value expressed as a number of clock ticks.
<code>secnds</code>	REAL*4	Gets the time in seconds from the real-time system clock. If the value is zero, the time in seconds from midnight is used.
<code>short</code>	INTEGER*2	Converts INTEGER*4 to INTEGER*2.
<code>signal</code>	INTEGER*4	Specifies the action to take upon delivery of a signal.
<code>sleep</code>	None	Puts the calling kernel thread to sleep, requiring it to wait for a wakeup to be issued to continue to run. Provided for compatibility with older code and should not be used with new code.
<code>srand1</code>	None	Sets the seed for the pseudo-random number generation that <code>rand1</code> provides.
<code>srand2</code>	None	Sets the seed for the pseudo-random number generation that <code>rand2</code> provides.
<code>stat</code>	INTEGER*4	Obtains information about the specified file.
<code>stat64</code>	INTEGER*4	Obtains information in a 64-bit structure about the specified file.
<code>stime</code>	INTEGER*4	Sets the current value of the specified parameter for the system-wide timer.
<code>symlink</code>	INTEGER*4	Creates a symbolic link with the specified name to the specified file.
<code>system</code>	INTEGER*4	Runs a shell command.
<code>time</code>	INTEGER*4	Returns the time in seconds since January 1, 1970.
<code>timef</code>	REAL*8	Returns the elapsed time in milliseconds since the first call to <code>timef</code> .
<code>times</code>	INTEGER*4	Fills the specified structure with time-accounting information.
<code>ttynam</code>	STRING(100)	Either gets the path name of the terminal or determines if the device is a terminal.
<code>unlink</code>	INTEGER*4	Removes the specified directory entry, and decreases the link count of the file referenced by the link.
<code>wait</code>	INTEGER*4	Suspends the calling thread until the process receives a signal that is not blocked or ignored, or until the calling process' child processes stop or terminate.

Using the DFWIN module

The DFWIN module includes all the modules needed to access the Win32 API. You can use modules supporting specific portions of the Win32 API separately. DFWIN is the only module you need to access the Fortran interfaces to the Win32 API. To use this module, add the following line to your Fortran code.

```
use dfwin
```

To utilize any of the Win32 API interfaces, you can add a Fortran use statement for the specific library or module that includes it. For example, to use user32.lib, add the following Fortran use statement:

```
use user32
```

Function calls made through the module interfaces ultimately resolve to C Language interfaces, so some accommodation for inter-language calling conventions must be made in the Fortran application. These accommodations include:

- On x64 platforms, pointers and pointer types such as HANDLE, HINSTANCE, WPARAM, and HWND must be treated as 8-byte quantities (INTEGER(8)). On x86 (32-bit) platforms, these are 4-byte quantities (INTEGER(4)).
- In general, C makes calls by value while Fortran makes calls by reference.
- When doing Windows development one must sometimes provide callback functions for message processing, dialog processing, etc. These routines are called by the Windows system when events are processed. To provide the expected function signature for a callback function, the user may need to use the STDCALL attribute directive (!DEC\$ ATTRIBUTE: :STDCALL) in the declaration.

Supported Libraries and Modules

The following tables provide lists of the functions in each library or module that PGI supports in DFWIN.

Note

For information on the interfaces associated with these functions, refer to the files located here:

```
C:\Program Files\PGI\win32\10.0-0\src
```

or

```
C:\Program Files\PGI\win64\10.0-0\src
```

advapi32

The following table lists the functions that advapi32 includes:

Table 9.5. DFWIN advapi32 Functions

AccessCheckAndAuditAlarm	AccessCheckByType
AccessCheckByTypeAndAuditAlarm	AccessCheckByTypeResultList
AccessCheckByTypeResultListAndAuditAlarm	AccessCheckByTypeResultListAndAuditAlarmByHandle
AddAccessAllowedAce	AddAccessAllowedAceEx
AddAccessAllowedObjectAce	AddAccessDeniedAce

AddAccessDeniedAceEx	AddAccessDeniedObjectAce
AddAce	AddAuditAccessAce
AddAuditAccessAceEx	AddAuditAccessObjectAce
AdjustTokenGroups	AdjustTokenPrivileges
AllocateAndInitializeSid	AllocateLocallyUniqueId
AreAllAccessesGranted	AreAnyAccessesGranted
BackupEventLog	CheckTokenMembership
ClearEventLog	CloseEncryptedFileRaw
CloseEventLog	ConvertToAutoInheritPrivateObjectSecurity
CopySid	CreatePrivateObjectSecurity
CreatePrivateObjectSecurityEx	CreatePrivateObjectSecurityWithMultipleInheritance
CreateProcessAsUser	CreateProcessWithLogonW
CreateProcessWithTokenW	CreateRestrictedToken
CreateWellKnownSid	DecryptFile
DeleteAce	DeregisterEventSource
DestroyPrivateObjectSecurity	DuplicateToken
DuplicateTokenEx	EncryptFile
EqualDomainSid	EqualPrefixSid
EqualSid	FileEncryptionStatus
FindFirstFreeAce	FreeSid
GetAce	GetAclInformation
GetCurrentHwProfile	GetEventLogInformation
GetFileSecurity	GetKernelObjectSecurity
GetLengthSid	GetNumberOfEventLogRecords
GetOldestEventLogRecord	GetPrivateObjectSecurity
GetSecurityDescriptorControl	GetSecurityDescriptorDacl
GetSecurityDescriptorGroup	GetSecurityDescriptorLength
GetSecurityDescriptorOwner	GetSecurityDescriptorRMControl
GetSecurityDescriptorSacl	GetSidIdentifierAuthority
GetSidLengthRequired	GetSidSubAuthority
GetSidSubAuthorityCount	GetTokenInformation
GetUserName	GetWindowsAccountDomainSid
ImpersonateAnonymousToken	ImpersonateLoggedOnUser
ImpersonateNamedPipeClient	ImpersonateSelf
InitializeAcl	InitializeSecurityDescriptor

InitializeSid	IsTextUnicode
IsTokenRestricted	IsTokenUntrusted

comdlg32

The following table lists the functions that `comdlg32` includes:

AfxReplaceText	ChooseColor	ChooseFont
CommDlgExtendedError	FindText	GetFileTitle
GetOpenFileName	GetSaveFileName	PageSetupDlg
PrintDlg	PrintDlgEx	ReplaceText

dfwbase

These are the functions that `dfwbase` includes:

<code>chartoint</code>	<code>LoByte</code>	<code>MakeWord</code>
<code>chartoreal</code>	<code>LoWord</code>	<code>MakeWparam</code>
<code>CopyMemory</code>	<code>LoWord64</code>	<code>PaletteIndex</code>
<code>GetBlueValue</code>	<code>MakeIntAtom</code>	<code>PaletteRGB</code>
<code>GetGreenValue</code>	<code>MakeIntResource</code>	<code>PrimaryLangID</code>
<code>GetRedValue</code>	<code>MakeLangID</code>	<code>RGB</code>
<code>HiByte</code>	<code>MakeLCID</code>	<code>RtlCopyMemory</code>
<code>HiWord</code>	<code>MakeLong</code>	<code>SortIDFromLCID</code>
<code>HiWord64</code>	<code>MakeLParam</code>	<code>SubLangID</code>
<code>inttochar</code>	<code>MakeLResult</code>	

dfwinty

These are the functions that `dfwinty` includes:

<code>dwNumberOfFunctionKeys</code>	<code>rdFunction</code>
-------------------------------------	-------------------------

gdi32

These are the functions that `gdi32` includes:

<code>AbortDoc</code>	<code>AbortPath</code>	<code>AddFontMemResourceEx</code>
<code>AddFontResource</code>	<code>AddFontResourceEx</code>	<code>AlphaBlend</code>
<code>AngleArc</code>	<code>AnimatePalette</code>	<code>Arc</code>
<code>ArcTo</code>	<code>BeginPath</code>	<code>BitBlt</code>
<code>CancelDC</code>	<code>CheckColorsInGamut</code>	<code>ChoosePixelFormat</code>
<code>Chord</code>	<code>CloseEnhMetaFile</code>	<code>CloseFigure</code>
<code>CloseMetaFile</code>	<code>ColorCorrectPalette</code>	<code>ColorMatchToTarget</code>
<code>CombineRgn</code>	<code>CombineTransform</code>	<code>CopyEnhMetaFile</code>
<code>CopyMetaFile</code>	<code>CreateBitmap</code>	<code>CreateBitmapIndirect</code>
<code>CreateBrushIndirect</code>	<code>CreateColorSpace</code>	<code>CreateCompatibleBitmap</code>
<code>CreateCompatibleDC</code>	<code>CreateDC</code>	<code>CreateDIBitmap</code>
<code>CreateDIBPatternBrush</code>	<code>CreateDIBPatternBrushPt</code>	<code>CreateDIBSection</code>
<code>CreateDiscardableBitmap</code>	<code>CreateEllipticRgn</code>	<code>CreateEllipticRgnIndirect</code>
<code>CreateEnhMetaFile</code>	<code>CreateFont</code>	<code>CreateFontIndirect</code>
<code>CreateFontIndirectEx</code>	<code>CreateHalftonePalette</code>	<code>CreateHatchBrush</code>

ioctlsocket	listen	ntohl
ntohs	recv	select
send	sendto	setsockopt
shutdown	socket	TransmitFile
WSAAsyncGetHostByName	WSAAsyncGetProtoByName	WSAAsyncGetProtoByNumber
WSAAsyncGetServByName	WSAAsyncGetServByPort	WSAAsyncSelect
WSACancelAsyncRequest	WSACancelBlockingCall	WSACleanup
WSAGetLastError	WSAIsBlocking	WSARecvEx
WSASetBlockingHook	WSASetLastError	WSAStartup

Chapter 10. Messages

This chapter describes the various messages that the compiler produces. These messages include the sign-on message and diagnostic messages for remarks, warnings, and errors. The compiler always displays any error messages, along with the erroneous source line, on the screen. If you specify the `-Mlist` option, the compiler places any error messages in the listing file. You can also use the `-v` option to display more information about the compiler, assembler, and linker invocations and about the host system. For more information on the `-Mlist` and `-v` options, refer to “using Command Line Options” in the PGI Compiler User’s Guide.

Diagnostic Messages

Diagnostic messages provide syntactic and semantic information about your source text. Syntactic information includes information such as syntax errors. Semantic information includes information such as unreachable code.

You can specify that the compiler displays error messages at a certain level with the `-Minform` option.

The compiler messages refer to a severity level, a message number, and the line number where the error occurs.

The compiler can also display internal error messages on standard error. If your compilation produces any internal errors, contact The Portland Group’s technical reporting service by sending e-mail to trs@pgroup.com.

If you use the listing file option `-Mlist`, the compiler places diagnostic messages after the source lines in the listing file, in the following format:

```
PGFTN-etype-enum-message (filename: line)
```

Where:

`etype`

is a character signifying the severity level

`enum`

is the error number

message
is the error message

filename
is the source filename

line
is the line number where the compiler detected an error.

Phase Invocation Messages

You can display compiler, assembler, and linker phase invocations by using the `-v` command line option. For further information about this option, refer to “Using Command Line Options” in the PGI Compiler User’s Guide.

Fortran Compiler Error Messages

This section presents the error messages generated by the PGF77, PGF95, and PGFORTRAN compilers. The compilers display error messages in the program listing and on standard output. They can also display internal error messages on standard error.

Message Format

Each message is numbered. Each message also lists the line and column number where the error occurs. A dollar sign (\$) in a message represents information that is specific to each occurrence of the message.

Message List

Error message severities:

I
informative

W
warning

S
severe error

F
fatal error

V
variable

V000 Internal compiler error. \$ \$

This message indicates an error in the compiler, rather than a user error – although it may be possible for a user error to cause an internal error. The severity may vary; if it is informative or warning, correct object code was probably generated, but it is not safe to rely on this. Regardless of the severity or cause, internal errors should be reported to trs@pgroup.com.

F001 Source input file name not specified

On the command line, source file name should be specified either before all the switches, or after them.

F002 Unable to open source input file: \$

Source file name is misspelled, file is not in current working directory, or file is read protected.

F003 Unable to open listing file

Probably, user does not have write permission for the current working directory.

F004 \$ \$

Generic message for file errors.

F005 Unable to open temporary file

Compiler uses directory specified by the environment variables \$TMP or \$TMPDIR in which to create temporary files. If neither of these directories is available on the node on which the compiler is being used, this error will occur.

S006 Input file empty

Source input file does not contain any Fortran statements other than comments or compiler directives.

F007 Subprogram too large to compile at this optimization level \$

Internal compiler data structure overflow, working storage exhausted, or some other non-recoverable problem related to the size of the subprogram. If this error occurs at opt 2, reducing the opt level to 1 may work around the problem. Moving the subprogram being compiled to its own source file may eliminate the problem. If this error occurs while compiling a subprogram of fewer than 2000 statements it should be reported to the compiler maintenance group as a possible compiler problem.

F008 Error limit exceeded

The compiler gives up because too many severe errors were issued; the error limit can be reset on the command line.

F009 Unable to open assembly file

Probably, user does not have write permission for the current working directory.

F010 File write error occurred \$

Probably, file system is full.

S011 Unrecognized command line switch: \$

Refer to PDS reference document for list of allowed compiler switches.

S012 Value required for command line switch: \$

Certain switches require an immediately following value, such as "-opt 2".

S013 Unrecognized value specified for command line switch: \$**S014 Ambiguous command line switch: \$**

Too short an abbreviation was used for one of the switches.

W015 Hexadecimal or octal constant truncated to fit data type**I016 Identifier, \$, truncated to 63 chars**

An identifier may be at most 63 characters in length; characters after the 63st are ignored.

S017 Unable to open include file: \$

File is missing, read protected, or maximum include depth (10) exceeded. Remember that the file name should be enclosed in quotes.

S018 Illegal label \$ \$

Used for label 'field' errors or illegal values. E.g., in fixed source form, the label field (first five characters) of the indicated line contains a non-numeric character.

S019 Illegally placed continuation line

A continuation line does not follow an initial line, or more than 99 continuation lines were specified.

S020 Unrecognized compiler directive

Refer to user's manual for list of allowed compiler directives.

S021 Label field of continuation line is not blank

The first five characters of a continuation line must be blank.

S022 Unexpected end of file - missing END statement**S023 Syntax error - unbalanced \$**

Unbalanced parentheses or brackets.

W024 CHARACTER or Hollerith constant truncated to fit data type

A character or hollerith constant was converted to a data type that was not large enough to contain all of the characters in the constant. This type conversion occurs when the constant is used in an arithmetic expression or is assigned to a non-character variable. The character or hollerith constant is truncated on the right, that is, if 4 characters are needed then the first 4 are used and the remaining characters are discarded.

W025 Illegal character (\$) - ignored

The current line contains a character, possibly non-printing, which is not a legal Fortran character (characters inside of character or Hollerith constants cannot cause this error). As a general rule, all non-printing characters are treated as white space characters (blanks and tabs); no error message is generated when this occurs. If for some reason, a non-printing character is not treated as a white space character, its hex representation is printed in the form dd where each d is a hex digit.

S026 Unmatched quote**S027 Illegal integer constant: \$**

Integer constant is too large for 32 bit word.

S028 Illegal real or double precision constant: \$**S029 Illegal \$ constant: \$**

Illegal hexadecimal, octal, or binary constant. A hexadecimal constant consists of digits 0..9 and letters A..F or a..f; any other character in a hexadecimal constant is illegal. An octal constant consists of digits 0..7; any other digit or character in an octal constant is illegal. A binary constant consists of digits 0 or 1; any other digit or character in a binary constant is illegal.

S030 Explicit shape must be specified for \$**S031 Illegal data type length specifier for \$**

The data type length specifier (e.g. 4 in INTEGER*4) is not a constant expression that is a member of the set of allowed values for this particular data type.

W032 Data type length specifier not allowed for \$

The data type length specifier (e.g. 4 in INTEGER*4) is not allowed in the given syntax (e.g. DIMENSION A(10)*4).

S033 Illegal use of constant \$

A constant was used in an illegal context, such as on the left side of an assignment statement or as the target of a data initialization statement.

S034 Syntax error at or near \$**I035 Predefined intrinsic \$ loses intrinsic property**

An intrinsic name was used in a manner inconsistent with the language definition for that intrinsic. The compiler, based on the context, will treat the name as a variable or an external function.

S036 Illegal implicit character range

First character must alphabetically precede second.

S037 Contradictory data type specified for \$

The indicated identifier appears in more than one type specification statement and different data types are specified for it.

S038 Symbol, \$, has not been explicitly declared

The indicated identifier must be declared in a type statement; this is required when the IMPLICIT NONE statement occurs in the subprogram.

W039 Symbol, \$, appears illegally in a SAVE statement \$

An identifier appearing in a SAVE statement must be a local variable or array.

S040 Illegal common variable \$

Indicated identifier is a dummy variable, is already in a common block, or has previously been defined to be something other than a variable or array.

W041 Illegal use of dummy argument \$

This error can occur in several situations. It can occur if dummy arguments were specified on a PROGRAM statement. It can also occur if a dummy argument name occurs in a DATA, COMMON, SAVE, or EQUIVALENCE statement. A program statement must have an empty argument list.

S042 \$ is a duplicate dummy argument**S043 Illegal attempt to redefine \$ \$**

An attempt was made to define a symbol in a manner inconsistent with an earlier definition of the same symbol. This can happen for a number of reasons. The message attempts to indicate the situation that occurred.

intrinsic - An attempt was made to redefine an intrinsic function. A symbol that represents an intrinsic function may be redefined if that symbol has not been previously verified to be an intrinsic function. For example, the intrinsic `sin` can be defined to be an integer array. If a symbol is verified to be an intrinsic function via the INTRINSIC statement or via an intrinsic function reference then it must be referred to as an intrinsic function for the remainder of the program unit.

symbol - An attempt was made to redefine a symbol that was previously defined. An example of this is to declare a symbol to be a PARAMETER which was previously declared to be a subprogram argument.

S044 Multiple declaration for symbol \$

A redundant declaration of a symbol has occurred. For example, an attempt was made to declare a symbol as an ENTRY when that symbol was previously declared as an ENTRY.

S045 Data type of entry point \$ disagrees with function \$

The current function has entry points with data types inconsistent with the data type of the current function. For example, the function returns type character and an entry point returns type complex.

S046 Data type length specifier in wrong position

The CHARACTER data type specifier has a different position for the length specifier from the other data types. Suppose, we want to declare arrays ARRAYA and ARRAYB to have 8 elements each having an element length of 4 bytes. The difference is that ARRAYA is character and ARRAYB is integer. The declarations would be CHARACTER ARRAYA(8)*4 and INTEGER ARRAYB*4(8).

S047 More than seven dimensions specified for array**S048 Illegal use of '*' in declaration of array \$**

An asterisk may be used only as the upper bound of the last dimension.

S049 Illegal use of '*' in non-subroutine subprogram

The alternate return specifier '*' is legal only in the subroutine statement. Programs, functions, and block data are not allowed to have alternate return specifiers.

S050 Assumed size array, \$, is not a dummy argument**S051 Unrecognized built-in % function**

The allowable built-in functions are %VAL, %REF, %LOC, and %FILL. One was encountered that did not match one of these allowed forms.

S052 Illegal argument to %VAL or %LOC**S053 %REF or %VAL not legal in this context**

The built-in functions %REF and %VAL can only be used as actual parameters in procedure calls.

W054 Implicit character \$ used in a previous implicit statement

An implicit character has been given an implied data type more than once. The implied data type for the implicit character is changed anyway.

W055 Multiple implicit none statements

The IMPLICIT NONE statement can occur only once in a subprogram.

W056 Implicit type declaration

The -Mdcchk switch and an implicit declaration following an IMPLICIT NONE statement will produce a warning message for IMPLICIT statements.

S057 Illegal equivalence of dummy variable, \$

Dummy arguments may not appear in EQUIVALENCE statements.

S058 Equivalenced variables \$ and \$ not in same common block

A common block variable must not be equivalenced with a variable in another common block.

S059 Conflicting equivalence between \$ and \$

The indicated equivalence implies a storage layout inconsistent with other equivalences.

S060 Illegal equivalence of structure variable, \$

STRUCTURE and UNION variables may not appear in EQUIVALENCE statements.

S061 Equivalence of \$ and \$ extends common block backwards**W062 Equivalence forces \$ to be unaligned**

EQUIVALENCE statements have defined an address for the variable which has an alignment not optimal for variables of its data type. This can occur when INTEGER and CHARACTER data are equivalenced, for instance.

I063 Gap in common block \$ before \$**S064 Illegal use of \$ in DATA statement implied DO loop**

The indicated variable is referenced where it is not an active implied DO index variable.

S065 Repeat factor less than zero**S066 Too few data constants in initialization statement****S067 Too many data constants in initialization statement****S068 Numeric initializer for CHARACTER \$ out of range 0 through 255**

A CHARACTER*1 variable or character array element can be initialized to an integer, octal, or hexadecimal constant if that constant is in the range 0 through 255.

S069 Illegal implied DO expression

The only operations allowed within an implied DO expression are integer +, -, *, and /.

S070 Incorrect sequence of statements \$

The statement order is incorrect. For instance, an IMPLICIT NONE statement must precede a specification statement which in turn must precede an executable statement.

S071 Executable statements not allowed in block data**S072 Assignment operation illegal to \$ \$**

The destination of an assignment operation must be a variable, array reference, or vector reference. The assignment operation may be by way of an assignment statement, a data statement, or the index variable of an implied DO-loop. The compiler has determined that the identifier used as the destination is not a storage location. The error message attempts to indicate the type of entity used.

entry point - An assignment to an entry point that was not a function procedure was attempted.

external procedure - An assignment to an external procedure or a Fortran intrinsic name was attempted. If the identifier is the name of an entry point that is not a function, an external procedure.

S073 Intrinsic or predeclared, \$, cannot be passed as an argument**S074 Illegal number or type of arguments to \$ \$**

The indicated symbol is an intrinsic or generic function, or a predeclared subroutine or function, requiring a certain number of arguments of a fixed data type.

S075 Subscript, substring, or argument illegal in this context for \$

This can happen if you try to doubly index an array such as `ra(2)(3)`. This also applies to substring and function references.

S076 Subscripts specified for non-array variable \$**S077 Subscripts omitted from array \$****S078 Wrong number of subscripts specified for \$****S079 Keyword form of argument illegal in this context for \$\$****S080 Subscript for array \$ is out of bounds****S081 Illegal selector \$ \$****S082 Illegal substring expression for variable \$**

Substring expressions must be of type integer and if constant must be greater than zero.

S083 Vector expression used where scalar expression required

A vector expression was used in an illegal context. For example, `iscalar = iarray`, where a scalar is assigned the value of an array. Also, character and record references are not vectorizable.

S084 Illegal use of symbol \$ \$

This message is used for many different errors.

S085 Incorrect number of arguments to statement function \$**S086 Dummy argument to statement function must be a variable****S087 Non-constant expression where constant expression required****S088 Recursive subroutine or function call of \$**

A function may not call itself.

S089 Illegal use of symbol, \$, with character length = *

Symbols of type `CHARACTER(*)` must be dummy variables and must not be used as statement function dummy parameters and statement function names. Also, a dummy variable of type `CHARACTER(*)` cannot be used as a function.

S090 Hollerith constant more than 4 characters

In certain contexts, Hollerith constants may not be more than 4 characters long.

S091 Constant expression of wrong data type**S092 Illegal use of variable length character expression**

A character expression used as an actual argument, or in certain contexts within I/O statements, must not consist of a concatenation involving a passed length character variable.

W093 Type conversion of expression performed

An expression of some data type appears in a context which requires an expression of some other data type. The compiler generates code to convert the expression into the required type.

S094 Variable \$ is of wrong data type \$

The indicated variable is used in a context which requires a variable of some other data type.

S095 Expression has wrong data type

An expression of some data type appears in a context which requires an expression of some other data type.

S096 Illegal complex comparison

The relations .LT., .GT., .GE., and .LE. are not allowed for complex values.

S097 Statement label \$ has been defined more than once

More than one statement with the indicated statement number occurs in the subprogram.

S098 Divide by zero**S099 Illegal use of \$**

Aggregate record references may only appear in aggregate assignment statements, unformatted I/O statements, and as parameters to subprograms. They may not appear, for example, in expressions. Also, records with differing structure types may not be assigned to one another.

S100 Expression cannot be promoted to a vector

An expression was used that required a scalar quantity to be promoted to a vector illegally. For example, the assignment of a character constant string to a character array. Records, too, cannot be promoted to vectors.

S101 Vector operation not allowed on \$

Record and character typed entities may only be referenced as scalar quantities.

S102 Arithmetic IF expression has wrong data type

The parenthetical expression of an arithmetic if statement must be an integer, real, or double precision scalar expression.

S103 Type conversion of subscript expression for \$

The data type of a subscript expression must be integer. If it is not, it is converted.

S104 Illegal control structure \$

This message is issued for a number of errors involving IF-THEN statements, DO loops, and directives. You may see one of the following messages:

```
PGF90-S-0104-Illegal control structure - unterminated PARALLEL directive
```

```
PGF90-S-0104-Illegal control structure - unterminated block IF
```

If the line number specified is the last line (END statement) of the subprogram, the error is probably an unterminated DO loop or IF-THEN statement. If the message contains `unterminated PARALLEL directive`, it is likely you are missing the required `!$omp end parallel` directive.

S105 Unmatched ELSEIF, ELSE or ENDIF statement

An ELSEIF, ELSE, or ENDIF statement cannot be matched with a preceding IF-THEN statement.

S106 DO index variable must be a scalar variable

The DO index variable cannot be an array name, a subscripted variable, a PARAMETER name, a function name, a structure name, etc.

S107 Illegal assigned goto variable \$

S108 Illegal variable, \$, in NAMELIST group \$

A NAMELIST group can only consist of arrays and scalars which are not dummy arguments and pointer-based variables.

I109 Overflow in \$ constant \$, constant truncated at left

A non-decimal (hexadecimal, octal, or binary) constant requiring more than 64-bits produces an overflow. The constant is truncated at left (e.g. '1234567890abcdef1'x will be '234567890abcdef1'x).

I110 <reserved message number>**I111 Underflow of real or double precision constant****I112 Overflow of real or double precision constant****S113 Label \$ is referenced but never defined****S114 Cannot initialize \$****W115 Assignment to DO variable \$ in loop****S116 Illegal use of pointer-based variable \$ \$****S117 Statement not allowed within a \$ definition**

The statement may not appear in a STRUCTURE or derived type definition.

S118 Statement not allowed in DO, IF, or WHERE block**I119 Redundant specification for \$**

Data type of indicated symbol specified more than once.

I120 Label \$ is defined but never referenced**I121 Operation requires logical or integer data types**

An operation in an expression was attempted on data having a data type incompatible with the operation. For example, a logical expression can consist of only logical elements of type integer or logical. Real data would be invalid.

I122 Character string truncated

Character string or Hollerith constant appearing in a DATA statement or PARAMETER statement has been truncated to fit the declared size of the corresponding identifier.

W123 Hollerith length specification too big, reduced

The length specifier field of a hollerith constant specified more characters than were present in the character field of the hollerith constant. The length specifier was reduced to agree with the number of characters present.

S124 Relational expression mixes character with numeric data

A relational expression is used to compare two arithmetic expressions or two character expressions. A character expression cannot be compared to an arithmetic expression.

I125 Dummy procedure \$ not declared EXTERNAL

A dummy argument which is not declared in an EXTERNAL statement is used as the subprogram name in a CALL statement, or is called as a function, and is therefore assumed to be a dummy procedure. This message can result from a failure to declare a dummy array.

I126 Name \$ is not an intrinsic function

I127 Optimization level for \$ changed to opt 1 \$

W128 Integer constant truncated to fit data type: \$

An integer constant will be truncated when assigned to data types smaller than 32-bits, such as a BYTE.

I129 Floating point overflow. Check constants and constant expressions

I130 Floating point underflow. Check constants and constant expressions

I131 Integer overflow. Check floating point expressions cast to integer

I132 Floating pt. invalid oprnd. Check constants and constant expressions

I133 Divide by 0.0. Check constants and constant expressions

S134 Illegal attribute \$ \$

W135 Missing STRUCTURE name field

A STRUCTURE name field is required on the outermost structure.

W136 Field-namelist not allowed

The field-namelist field of the STRUCTURE statement is disallowed on the outermost structure.

W137 Field-namelist is required in nested structures

W138 Multiply defined STRUCTURE member name \$

A member name was used more than once within a structure.

W139 Structure \$ in RECORD statement not defined

A RECORD statement contains a reference to a STRUCTURE that has not yet been defined.

S140 Variable \$ is not a RECORD

S141 RECORD required on left of \$

S142 \$ is not a member of this RECORD

S143 \$ requires initializer

W144 NEED ERROR MESSAGE \$ \$

This is used as a temporary message for compiler development.

W145 %FILL only valid within STRUCTURE block

The %FILL special name was used outside of a STRUCTURE multiline statement. It is only valid when used within a STRUCTURE multiline statement even though it is ignored.

S146 Expression must be character type

S147 Character expression not allowed in this context

S148 Reference to \$ required

An aggregate reference to a record was expected during statement compilation but another data type was found instead.

S149 Record where arithmetic value required

An aggregate record reference was encountered when an arithmetic expression was expected.

S150 Structure, Record, derived type, or member \$ not allowed in this context

A structure, record, or member reference was found in a context which is not supported. For example, the use of structures, records, or members within a data statement is disallowed.

S151 Empty TYPE, STRUCTURE, UNION, or MAP

TYPE - ENDTYPE, STRUCTURE - ENDSTRUCTURE, UNION - ENDUNION MAP - ENDMAP declaration contains no members.

S152 All dimension specifiers must be ':'**S153 Array objects are not conformable \$****S154 DISTRIBUTE target, \$, must be a processor****S155 \$ \$****S156 Number of colons and triplets must be equal in ALIGN \$ with \$****S157 Illegal subscript use of ALIGN dummy \$ - \$****S158 Alternate return not specified in SUBROUTINE or ENTRY**

An alternate return can only be used if alternate return specifiers appeared in the SUBROUTINE or ENTRY statements.

S159 Alternate return illegal in FUNCTION subprogram

An alternate return cannot be used in a FUNCTION.

S160 ENDSTRUCTURE, ENDUNION, or ENDMAP does not match top**S161 Vector subscript must be rank-one array****W162 Not equal test of loop control variable \$ replaced with < or > test.****S163 <reserved message number>****S164 Overlapping data initializations of \$**

An attempt was made to data initialize a variable or array element already initialized.

S165 \$ appeared more than once as a subprogram

A subprogram name appeared more than once in the source file. The message is applicable only when an assembly file is the output of the compiler.

S166 \$ cannot be a common block and a subprogram

A name appeared as a common block name and a subprogram name. The message is applicable only when an assembly file is the output of the compiler.

I167 Inconsistent size of common block \$

A common block occurs in more than one subprogram of a source file and its size is not identical. The maximum size is chosen. The message is applicable only when an assembly file is the output of the compiler.

S168 Incompatible size of common block \$

A common block occurs in more than one subprogram of a source file and is initialized in one subprogram. Its initialized size was found to be less than its size in the other subprogram(s). The message is applicable only when an assembly file is the output of the compiler.

W169 Multiple data initializations of common block \$

A common block is initialized in more than one subprogram of a source file. Only the first set of initializations apply. The message is applicable only when an assembly file is the output of the compiler.

W170 PGI Fortran extension: \$ \$

Use of a nonstandard feature. A description of the feature is provided.

W171 PGI Fortran extension: nonstandard statement type \$**W172 PGI Fortran extension: numeric initialization of CHARACTER \$**

A CHARACTER*1 variable or array element was initialized with a numeric value.

W173 PGI Fortran extension: nonstandard use of data type length specifier**W174 PGI Fortran extension: type declaration contains data initialization****W175 PGI Fortran extension: IMPLICIT range contains nonalpha characters****W176 PGI Fortran extension: nonstandard operator \$****W177 PGI Fortran extension: nonstandard use of keyword argument \$****W178 <reserved message number>****W179 PGI Fortran extension: use of structure field reference \$****W180 PGI Fortran extension: nonstandard form of constant****W181 PGI Fortran extension: & alternate return****W182 PGI Fortran extension: mixed non-character and character elements in COMMON \$****W183 PGI Fortran extension: mixed non-character and character EQUIVALENCE (\$,\$)****W184 Mixed type elements (numeric and/or character types) in COMMON \$****W185 Mixed numeric and/or character type EQUIVALENCE (\$,\$)**

S186 Argument missing for formal argument \$

S187 Too many arguments specified for \$

S188 Argument number \$ to \$: type mismatch

S189 Argument number \$ to \$: association of scalar actual argument to array dummy argument

S190 Argument number \$ to \$: non-conformable arrays

S191 Argument number \$ to \$ cannot be an assumed-size array

S192 Argument number \$ to \$ must be a label

W193 Argument number \$ to \$ does not match INTENT (OUT)

W194 INTENT(IN) argument cannot be defined - \$

S195 Statement may not appear in an INTERFACE block \$

S196 Deferred-shape specifiers are required for \$

S197 Invalid qualifier or qualifier value (/ \$) in OPTIONS statement

An illegal qualifier was found or a value was specified for a qualifier which does not expect a value. In either case, the qualifier for which the error occurred is indicated in the error message.

S198 \$ \$ in ALLOCATE/DEALLOCATE

W199 Unaligned memory reference

A memory reference occurred whose address does not meet its data alignment requirement.

S200 Missing UNIT/FILE specifier

S201 Illegal I/O specifier - \$

S202 Repeated I/O specifier - \$

S203 FORMAT statement has no label

S204 \$ \$

Miscellaneous I/O error.

S205 Illegal specification of scale factor

The integer following + or - has been omitted, or P does not follow the integer value.

S206 Repeat count is zero

S207 Integer constant expected in edit descriptor

S208 Period expected in edit descriptor

S209 Illegal edit descriptor

S210 Exponent width not used in the Ew.dEe or Gw.dEe edit descriptors

S211 Internal I/O not allowed in this I/O statement

S212 Illegal NAMELIST I/O

Namelist I/O cannot be performed with internal, unformatted, formatted, and list-directed I/O. Also, I/O lists must not be present.

S213 \$ is not a NAMELIST group name

S214 Input item is not a variable reference

S215 Assumed sized array name cannot be used as an I/O item or specifier

An assumed size array was used as an item to be read or written or as an I/O specifier (i.e., FMT = array-name). In these contexts the size of the array must be known.

S216 STRUCTURE/UNION cannot be used as an I/O item

S217 ENCODE/DECODE buffer must be a variable, array, or array element

S218 Statement labeled \$ \$

S219 <reserved message number>

S220 Redefining predefined macro \$

S221 #elif after #else

A preprocessor #elif directive was found after a #else directive; only #endif is allowed in this context.

S222 #else after #else

A preprocessor #else directive was found after a #else directive; only #endif is allowed in this context.

S223 #if-directives too deeply nested

Preprocessor #if directive nesting exceeded the maximum allowed (currently 10).

S224 Actual parameters too long for \$

The total length of the parameters in a macro call to the indicated macro exceeded the maximum allowed (currently 2048).

W225 Argument mismatch for \$

The number of arguments supplied in the call to the indicated macro did not agree with the number of parameters in the macro's definition.

F226 Can't find include file \$

The indicated include file could not be opened.

S227 Definition too long for \$

The length of the macro definition of the indicated macro exceeded the maximum allowed (currently 2048).

S228 EOF in comment

The end of a file was encountered while processing a comment.

S229 EOF in macro call to \$

The end of a file was encountered while processing a call to the indicated macro.

S230 EOF in string

The end of a file was encountered while processing a quoted string.

S231 Formal parameters too long for \$

The total length of the parameters in the definition of the indicated macro exceeded the maximum allowed (currently 2048).

S232 Identifier too long

The length of an identifier exceeded the maximum allowed (currently 2048).

S233 <reserved message number>**W234 Illegal directive name**

The sequence of characters following a # sign was not an identifier.

W235 Illegal macro name

A macro name was not an identifier.

S236 Illegal number \$

The indicated number contained a syntax error.

F237 Line too long

The input source line length exceeded the maximum allowed (currently 2048).

W238 Missing #endif

End of file was encountered before a required #endif directive was found.

W239 Missing argument list for \$

A call of the indicated macro had no argument list.

S240 Number too long

The length of a number exceeded the maximum allowed (currently 2048).

W241 Redefinition of symbol \$

The indicated macro name was redefined.

I242 Redundant definition for symbol \$

A definition for the indicated macro name was found that was the same as a previous definition.

F243 String too long

The length of a quoted string exceeded the maximum allowed (currently 2048).

S244 Syntax error in #define, formal \$ not identifier

A formal parameter that was not an identifier was used in a macro definition.

W245 Syntax error in #define, missing blank after name or arglist

There was no space or tab between a macro name or argument list and the macro's definition.

S246 Syntax error in #if

A syntax error was found while parsing the expression following a #if or #elif directive.

S247 Syntax error in #include

The #include directive was not correctly formed.

W248 Syntax error in #line

A #line directive was not correctly formed.

W249 Syntax error in #module

A #module directive was not correctly formed.

W250 Syntax error in #undef

A #undef directive was not correctly formed.

W251 Token after #ifdef must be identifier

The #ifdef directive was not followed by an identifier.

W252 Token after #ifndef must be identifier

The #ifndef directive was not followed by an identifier.

S253 Too many actual parameters to \$

The number of actual arguments to the indicated macro exceeded the maximum allowed (currently 31).

S254 Too many formal parameters to \$

The number of formal arguments to the indicated macro exceeded the maximum allowed (currently 31).

F255 Too much pushback

The preprocessor ran out of space while processing a macro expansion. The macro may be recursive.

W256 Undefined directive \$

The identifier following a # was not a directive name.

F257 POS value must be positive.

A value for POS ≤ 0 was encountered. Negative and 0 values are illegal for a position in a file..

S257 EOF in #include directive

End of file was encountered while processing a #include directive.

S258 Unmatched #elif

A #elif directive was encountered with no preceding #if or #elif directive.

S259 Unmatched #else

A #else directive was encountered with no preceding #if or #elif directive.

S260 Unmatched #endif

A #endif directive was encountered with no preceding #if, #ifdef, or #ifndef directive.

S261 Include files nested too deeply

The nesting depth of #include directives exceeded the maximum (currently 20).

S262 Unterminated macro definition for \$

A newline was encountered in the formal parameter list for the indicated macro.

S263 Unterminated string or character constant

A newline with no preceding backslash was found in a quoted string.

I264 Possible nested comment

The characters /* were found within a comment.

S265 <reserved message number>

S266 <reserved message number>

S267 <reserved message number>

W268 Cannot inline subprogram; common block mismatch

W269 Cannot inline subprogram; argument type mismatch

This message may be Severe if the compilation has gone too far to undo the inlining process.

F270 Missing -exlib option

W271 Can't inline \$ - wrong number of arguments

I272 Argument of inlined function not used

S273 Inline library not specified on command line (-inlib switch)

F274 Unable to access file \$/TOC

S275 Unable to open file \$ while extracting or inlining

F276 Assignment to constant actual parameter in inlined subprogram

I277 Inlining of function \$ may result in recursion

S278 <reserved message number>

W279 Possible use of \$ before definition in \$

The optimizer has detected the possibility that a variable is used before it has been assigned a value. The names of the variable and the function in which the use occurred are listed. The line number, if specified, is the line number of the basic block containing the use of the variable.

W280 Syntax error in directive \$

Messages 280-300 reserved for directives. handling

W281 Directive ignored - \$ \$

S300 Too few data constants in initialization of derived type \$

S301 \$ must be TEMPLATE or PROCESSOR

S302 Unmatched END\$ statement

S303 END statement for \$ required in an interface block

S304 EXIT/CYCLE statement must appear in a DO/DOWHILE loop\$\$

S305 \$ cannot be named, \$

S306 \$ names more than one construct

S307 \$ must have the construct name \$

S308 DO may not terminate at an EXIT, CYCLE, RETURN, STOP, GOTO, or arithmetic IF

S309 Incorrect name, \$, specified in END statement

S310 \$ \$

Generic message for MODULE errors.

W311 Non-replicated mapping for \$ array, \$, ignored

W312 Array \$ should be declared SEQUENCE

W313 Subprogram \$ called within INDEPENDENT loop not PURE

E314 IPA: actual argument \$ is a label, but dummy argument \$ is not an asterisk

The call passes a label to the subprogram; the corresponding dummy argument in the subprogram should be an asterisk to declare this as the alternate return.

I315 IPA: routine \$, \$ constant dummy arguments

This many dummy arguments are being replaced by constants due to interprocedural analysis.

I316 IPA: routine \$, \$ INTENT(IN) dummy arguments

This many dummy arguments are being marked as INTENT(IN) due to interprocedural analysis.

I317 IPA: routine \$, \$ array alignments propagated

This many array alignments were propagated by interprocedural analysis.

I318 IPA: routine \$, \$ distribution formats propagated

This many array distribution formats were propagated by interprocedural analysis.

I319 IPA: routine \$, \$ distribution targets propagated

This many array distribution targets were propagated by interprocedural analysis.

I320 IPA: routine \$, \$ common blocks optimized

This many mapped common blocks were optimized by interprocedural analysis.

I321 IPA: routine \$, \$ common blocks not optimized

This many mapped common blocks were not optimized by interprocedural analysis, either because they were declared differently in different routines, or they did not appear in the main program.

I322 IPA: analyzing main program \$

Interprocedural analysis is building the call graph and propagating information with the named main program.

I323 IPA: collecting information for \$

Interprocedural analysis is saving information for the current subprogram for subsequent analysis and propagation.

W324 IPA file \$ appears to be out of date

W325 IPA file \$ is for wrong subprogram: \$

W326 Unable to open file \$ to propagate IPA information to \$

I327 IPA: \$ subprograms analyzed

I328 IPA: \$ dummy arguments replaced by constants

I329 IPA: \$ INTENT(IN) dummy arguments should be INTENT(INOUT)

I330 IPA: \$ dummy arguments changed to INTENT(IN)

I331 IPA: \$ inherited array alignments replaced

I332 IPA: \$ transcriptive distribution formats replaced

I333 IPA: \$ transcriptive distribution targets replaced

I334 IPA: \$ descriptive/prescriptive array alignments verified

I335 IPA: \$ descriptive/prescriptive distribution formats verified

I336 IPA: \$ descriptive/prescriptive distribution targets verified

I337 IPA: \$ common blocks optimized

I338 IPA: \$ common blocks not optimized

S339 Bad IPA contents file: \$

S340 Bad IPA file format: \$

S341 Unable to create file \$ while analyzing IPA information

S342 Unable to open file \$ while analyzing IPA information

S343 Unable to open IPA contents file \$

S344 Unable to create file \$ while collecting IPA information

F345 Internal error in \$: table overflow
Analysis failed due to a table overflowing its maximum size.

W346 Subprogram \$ appears twice
The subprogram appears twice in the same source file; IPA will ignore the first appearance.

F347 Missing -ipalib option
Interprocedural analysis, enabled with the `-ipacollect`, `-ipaanalyze`, or `-ipapropagate` options, requires the `-ipalib` option to specify the library directory.

W348 Common /\$/ \$ has different distribution target
The array was declared in a common block with a different distribution target in another subprogram.

W349 Common /\$/ \$ has different distribution format
The array was declared in a common block with a different distribution format in another subprogram.

W350 Common /\$/ \$ has different alignment
The array was declared in a common block with a different alignment in another subprogram.

W351 Wrong number of arguments passed to \$
The subroutine or function statement for the given subprogram has a different number of dummy arguments than appear in the call.

W352 Wrong number of arguments passed to \$ when bound to \$

The subroutine or function statement for the given subprogram has a different number of dummy arguments than appear in the call to the EXTERNAL name given.

W353 Subprogram \$ is missing

A call to a subroutine or function with this name appears, but it could not be found or analyzed.

I354 Subprogram \$ is not called

No calls to the given subroutine or function appear anywhere in the program.

W355 Missing argument in call to \$

A nonoptional argument is missing in a call to the given subprogram.

I356 Array section analysis incomplete

Interprocedural analysis for array section arguments is incomplete; some information may not be available for optimization.

I357 Expression analysis incomplete

Interprocedural analysis for expression arguments is incomplete; some information may not be available for optimization.

W358 Dummy argument \$ is EXTERNAL, but actual is not subprogram

The call statement passes a scalar or array to a dummy argument that is declared EXTERNAL.

W359 SUBROUTINE \$ passed to FUNCTION dummy argument \$

The call statement passes a subroutine name to a dummy argument that is used as a function.

W360 FUNCTION \$ passed to FUNCTION dummy argument \$ with different result type

The call statement passes a function argument to a function dummy argument, but the dummy has a different result type.

W361 FUNCTION \$ passed to SUBROUTINE dummy argument \$

The call statement passes a function name to a dummy argument that is used as a subroutine.

W362 Argument \$ has a different type than dummy argument \$

The type of the actual argument is different than the type of the corresponding dummy argument.

W363 Dummy argument \$ is a POINTER but actual argument \$ is not

The dummy argument is a pointer, so the actual argument must be also.

W364 Array or array expression passed to scalar dummy argument \$

The actual argument is an array, but the dummy argument is a scalar variable.

W365 Scalar or scalar expression passed to array dummy argument \$

The actual argument is a scalar variable, but the dummy argument is an array.

F366 Internal error: interprocedural analysis fails

An internal error occurred during interprocedural analysis; please report this to the compiler maintenance group. If user errors were reported when collecting IPA information or during IPA analysis, correcting them may avoid this error.

I367 Array \$ bounds cannot be matched to formal argument

Passing a nonsequential array to a sequential dummy argument may require copying the array to sequential storage. The most common cause is passing an ALLOCATABLE array or array expression to a dummy argument that is declared with explicit bounds. Declaring the dummy argument as assumed shape, with bounds (:,:,:), will remove this warning.

W368 Array-valued expression passed to scalar dummy argument \$

The actual argument is an array-valued expression, but the dummy argument is a scalar variable.

W369 Dummy argument \$ has different rank than actual argument

The actual argument is an array or array-valued expression with a different rank than the dummy argument.

W370 Dummy argument \$ has different shape than actual argument

The actual argument is an array or array-valued expression with a different shape than the dummy argument; this may require copying the actual argument into sequential storage.

W371 Dummy argument \$ is INTENT(IN) but may be modified

The dummy argument was declared as INTENT(IN), but analysis has found that the argument may be modified; the INTENT(IN) declaration should be changed.

W372 Cannot propagate alignment from \$ to \$

The most common cause is when passing an array with an inherited alignment to a dummy argument with non-inherited alignment.

I373 Cannot propagate distribution format from \$ to \$

The most common cause is when passing an array with a transcriptive distribution format to a dummy argument with prescriptive or descriptive distribution format.

I374 Cannot propagate distribution target from \$ to \$

The most common cause is when passing an array with a transcriptive distribution target to a dummy argument with prescriptive or descriptive distribution target.

I375 Distribution format mismatch between \$ and \$

Usually this arises when the actual and dummy arguments are distributed in different dimensions.

I376 Alignment stride mismatch between \$ and \$

This may arise when the actual argument has a different stride in its alignment to its template than does the dummy argument.

I377 Alignment offset mismatch between \$ and \$

This may arise when the actual argument has a different offset in its alignment to its template than does the dummy argument.

I378 Distribution target mismatch between \$ and \$

This may arise when the actual and dummy arguments have different distribution target sizes.

I379 Alignment of \$ is too complex

The alignment specification of the array is too complex for interprocedural analysis to verify or propagate; the program will work correctly, but without the benefit of IPA.

I380 Distribution format of \$ is too complex

The distribution format specification of the array is too complex for interprocedural analysis to verify or propagate; the program will work correctly, but without the benefit of IPA.

I381 Distribution target of \$ is too complex

The distribution target specification of the array is too complex for interprocedural analysis to verify or propagate; the program will work correctly, but without the benefit of IPA.

I382 IPA: \$ subprograms analyzed

Interprocedural analysis succeeded in finding and analyzing this many subprograms in the whole program.

I383 IPA: \$ dummy arguments replaced by constants

Interprocedural analysis has found this many dummy arguments in the whole program that can be replaced by constants.

I384 IPA: \$ dummy arguments changed to INTENT(IN)

Interprocedural analysis has found this many dummy arguments in the whole program that are not modified and can be declared as INTENT(IN).

W385 IPA: \$ INTENT(IN) dummy arguments should be INTENT(INOUT)

Interprocedural analysis has found this many dummy arguments in the whole program that were declared as INTENT(IN) but should be INTENT(INOUT).

I386 IPA: \$ array alignments propagated

Interprocedural analysis has found this many array dummy arguments that could have the inherited array alignment replaced by a descriptive alignment.

I387 IPA: \$ array alignments verified

Interprocedural analysis has verified that the prescriptive or descriptive alignments of this many array dummy arguments match the alignments of the actual argument.

I388 IPA: \$ array distribution formats propagated

Interprocedural analysis has found this many array dummy arguments that could have the transcriptive distribution format replaced by a descriptive format.

I389 IPA: \$ array distribution formats verified

Interprocedural analysis has verified that the prescriptive or descriptive distribution formats of this many array dummy arguments match the formats of the actual argument.

I390 IPA: \$ array distribution targets propagated

Interprocedural analysis has found this many array dummy arguments that could have the transcriptive distribution target replaced by a descriptive target.

I391 IPA: \$ array distribution targets verified

Interprocedural analysis has verified that the prescriptive or descriptive distribution targets of this many array dummy arguments match the targets of the actual argument.

I392 IPA: \$ common blocks optimized

Interprocedural analysis has found this many common blocks that could be optimized.

I393 IPA: \$ common blocks not optimized

Interprocedural analysis has found this many common blocks that could not be optimized, either because the common block was not declared in the main program, or because it was declared differently in different subprograms.

I394 IPA: \$ replaced by constant value

The dummy argument was replaced by a constant as per interprocedural analysis.

I395 IPA: \$ changed to INTENT(IN)

The dummy argument was changed to INTENT(IN) as per interprocedural analysis.

I396 IPA: array alignment propagated to \$

The template alignment for the dummy argument was changed as per interprocedural analysis.

I397 IPA: distribution format propagated to \$

The distribution format for the dummy argument was changed as per interprocedural analysis.

I398 IPA: distribution target propagated to \$

The distribution target for the dummy argument was changed as per interprocedural analysis.

I399 IPA: common block \$ not optimized

The given common block was not optimized by interprocedural analysis either because it was not declared in the main program, or because it was declared differently in different subprograms.

E400 IPA: dummy argument \$ is an asterisk, but actual argument is not a label

The subprogram expects an alternate return label for this argument.

E401 Actual argument \$ is a subprogram, but Dummy argument \$ is not declared EXTERNAL

The call statement passes a function or subroutine name to a dummy argument that is a scalar variable or array.

E402 Actual argument \$ is illegal**E403 Actual argument \$ and formal argument \$ have different ranks**

The actual and formal array arguments differ in rank, which is allowed only if both arrays are declared with the HPF SEQUENCE attribute.

E404 Sequential array section of \$ in argument \$ is not contiguous

When passing an array section to a formal argument that has the HPF SEQUENCE attribute, the actual argument must be a whole array with the HPF SEQUENCE attribute, or an array section of such an array where the section is a contiguous sequence of elements.

E405 Array expression argument \$ may not be passed to sequential dummy argument \$

When the dummy argument has the HPF SEQUENCE attribute, the actual argument must be a whole array with the HPF SEQUENCE attribute or a contiguous array section of such an array, unless an INTERFACE block is used.

E406 Actual argument \$ and formal argument \$ have different character lengths

The actual and formal array character arguments have different character lengths, which is allowed only if both character arrays are declared with the HPF SEQUENCE attribute, unless an INTERFACE block is used.

W407 Argument \$ has a different character length than dummy argument \$

The character length of the actual argument is different than the length specified for the corresponding dummy argument.

W408 Specified main program \$ is not a PROGRAM

The main program specified on the command line is a subroutine, function, or block data subprogram.

W409 More than one main program in IPA directory: \$ and \$

There is more than one main program analyzed in the IPA directory shown. The first one found is used.

W410 No main program found; IPA analysis fails.

The main program must appear in the IPA directory for analysis to proceed.

W411 Formal argument \$ is DYNAMIC but actual argument is an expression**W412 Formal argument \$ is DYNAMIC but actual argument \$ is not****I413 Formal argument \$ has two reaching distributions and may be a candidate for cloning****I414 \$ and \$ may be aliased and one of them is assigned**

Interprocedural analysis has determined that two formal arguments may be aliased because the same variable is passed in both argument positions; or one formal argument and a global or COMMON variable may be aliased, because the global or COMMON variable is passed as an actual argument. If either alias is assigned in the subroutine, unexpected results may occur; this message alerts the user that this situation is disallowed by the Fortran standard.

F415 IPA fails: incorrect IPA file

Interprocedural analysis saves its information in special IPA files in the specified IPA directory. One of these files has been renamed or corrupted. This can arise when there are two files with the same prefix, such as `a.hpF` and `a.f90`.

E416 Argument \$ has the SEQUENCE attribute, but the dummy parameter \$ does not

When an actual argument is an array with the SEQUENCE attribute, the dummy parameter must have the SEQUENCE attribute or an INTERFACE block must be used.

E417 Interface block for \$ is a SUBROUTINE but should be a FUNCTION**E418 Interface block for \$ is a FUNCTION but should be a SUBROUTINE****E419 Interface block for \$ is a FUNCTION has wrong result type****W420 Earlier \$ directive overrides \$ directive**

W421 \$ directive can only appear in a function or subroutine

E422 Nonconstant DIM= argument is not supported

E423 Constant DIM= argument is out of range

E424 Equivalence using substring or vector triplets is not allowed

E425 A record is not allowed in this context

E426 WORD type cannot be converted

E427 Interface block for \$ has wrong number of arguments

E428 Interface block for \$ should have \$

E429 Interface block for \$ should not have \$

E430 Interface block for \$ has wrong \$

W431 Program is too large for Interprocedural Analysis to complete

W432 Illegal type conversion \$

E433 Subprogram \$ called within INDEPENDENT loop not LOCAL

W434 Incorrect home array specification ignored

S435 Array declared with zero size

An array was declared with a zero or negative dimension bound, as 'real a(-1)', or an upper bound less than the lower bound, as 'real a(4:2)'.

W436 Independent loop not parallelized\$

W437 Type \$ will be mapped to \$

Where DOUBLE PRECISION is not supported, it is mapped to REAL, and similarly for COMPLEX(16) or COMPLEX*32.

E438 \$ \$ not supported on this platform

This construct is not supported by the compiler for this target.

S439 An internal subprogram cannot be passed as argument - \$

S440 Defined assignment statements may not appear in WHERE statement or WHERE block

S441 \$ may not appear in a FORALL block

E442 Adjustable-length character type not supported on this host - \$ \$

S443 EQUIVALENCE of derived types not supported on this host - \$

S444 Derived type in EQUIVALENCE statement must have SEQUENCE attribute - \$

A variable or array with derived type appears in an EQUIVALENCE statement. The derived type must have the SEQUENCE attribute, but does not.

E445 Array bounds must be integer \$ \$

The expressions in the array bounds must be integer.

S446 Argument number \$ to \$: rank mismatch

The number of dimensions in the array or array expression does not match the number of dimensions in the dummy argument.

S447 Argument number \$ to \$ must be a subroutine or function name**S448 Argument number \$ to \$ must be a subroutine name****S449 Argument number \$ to \$ must be a function name****S450 Argument number \$ to \$: kind mismatch****S451 Arrays of derived type with a distributed member are not supported****S452 Assumed length character, \$, is not a dummy argument****S453 Derived type variable with pointer member not allowed in IO - \$ \$****S454 Subprogram \$ is not a module procedure**

Only names of module procedures declared in this module or accessed through USE association can appear in a MODULE PROCEDURE statement.

S455 A derived type array section cannot appear with a member array section - \$

A reference like A(:)%B(:), where 'A' is a derived type array and 'B' is a member array, is not allowed; a section subscript may appear after 'A' or after 'B', but not both.

S456 Unimplemented for data type for MATMUL**S457 Illegal expression in initialization****S458 Argument to NULL() must be a pointer****S459 Target of NULL() assignment must be a pointer****S460 ELEMENTAL procedures cannot be RECURSIVE****S461 Dummy arguments of ELEMENTAL procedures must be scalar****S462 Arguments and return values of ELEMENTAL procedures cannot have the POINTER attribute****S463 Arguments of ELEMENTAL procedures cannot be procedures****S464 An ELEMENTAL procedure cannot be passed as argument - \$**

Fortran Run-time Error Messages

This section presents the error messages generated by the run-time system. The run-time system displays error messages on standard output.

Message Format

The messages are numbered but have no severity indicators because they all terminate program execution.

Message List

Here are the run-time error messages:

201 illegal value for specifier

An improper specifier value has been passed to an I/O run-time routine. Example: within an OPEN statement, form='unknown'.

202 conflicting specifiers

Conflicting specifiers have been passed to an I/O run-time routine. Example: within an OPEN statement, form='unformatted', blank='null'.

203 record length must be specified

A recl specifier required for an I/O run-time routine has not been passed. Example: within an OPEN statement, access='direct' has been passed, but the record length has not been specified (recl=specifier).

204 illegal use of a readonly file

Self explanatory. Check file and directory modes for readonly status.

205 'SCRATCH' and 'SAVE'/'KEEP' both specified

In an OPEN statement, a file disposition conflict has occurred. Example: within an OPEN statement, status='scratch' and dispose='keep' have been passed.

206 attempt to open a named file as 'SCRATCH'

207 file is already connected to another unit

208 'NEW' specified for file that already exists

209 'OLD' specified for file that does not exist

210 dynamic memory allocation failed

Memory allocation operations occur only in conjunction with namelist I/O. The most probable cause of fixed buffer overflow is exceeding the maximum number of simultaneously open file units.

211 invalid file name

212 invalid unit number

A file unit number less than or equal to zero has been specified.

215 formatted/unformatted file conflict

Formatted/unformatted file operation conflict.

217 attempt to read past end of file

- 219 attempt to read/write past end of record**
For direct access, the record to be read/written exceeds the specified record length.
- 220 write after last internal record**
- 221 syntax error in format string**
A run-time encoded format contains a lexical or syntax error.
- 222 unbalanced parentheses in format string**
- 223 illegal P or T edit descriptor - value missing**
- 224 illegal Hollerith or character string in format**
An unknown token type has been found in a format encoded at run-time.
- 225 lexical error -- unknown token type**
- 226 unrecognized edit descriptor letter in format**
An unexpected Fortran edit descriptor (FED) was found in a run-time format item.
- 228 end of file reached without finding group**
- 229 end of file reached while processing group**
- 230 scale factor out of range -128 to 127**
Fortran P edit descriptor scale factor not within range of -128 to 127.
- 231 error on data conversion**
- 233 too many constants to initialize group item**
- 234 invalid edit descriptor**
An invalid edit descriptor has been found in a format statement.
- 235 edit descriptor does not match item type**
Data types specified by I/O list item and corresponding edit descriptor conflict.
- 236 formatted record longer than 2000 characters**
- 237 quad precision type unsupported**
- 238 tab value out of range**
A tab value of less than one has been specified.
- 239 entity name is not member of group**
- 240 no initial left parenthesis in format string**
- 241 unexpected end of format string**
- 242 illegal operation on direct access file**
- 243 format parentheses nesting depth too great**
- 244 syntax error - entity name expected**
- 245 syntax error within group definition**

246 infinite format scan for edit descriptor
248 illegal subscript or substring specification
249 error in format - illegal E, F, G or D descriptor
250 error in format - number missing after '.', '-', or '+'
251 illegal character in format string
252 operation attempted after end of file
253 attempt to read non-existent record (direct access)
254 illegal repeat count in format
