1 Overview

The NVIDIA® Messaging Accelerator (VMA) library accelerates latency-sensitive and throughput-demanding TCP and UDP socket-based applications by offloading traffic from the user-space directly to the network interface card (NIC) or Host Channel Adapter (HCA), without going through the kernel and the standard IP stack (kernel-bypass).

VMA leverages the following benefits:
- Implements the legacy POSIX socket interface
- Increases:
  - Throughput
  - Packets per Second (PPS)
  - Requests per Second (RPS)
- Reduces:
  - Network latency
  - The magnitude of network latency spikes
  - Context switches and interrupts
  - Network congestion
  - Data copying and moving in unicast and multicast applications
- Improves CPU utilization
- Compatible with Ethernet

VMA can work on top of MLNX_OFED driver stack and on a lighter driver stack, MLNX_EN.
2 Intended Audience

- Market data professionals
- Messaging specialists
- Software engineers and architects
- Systems administrators tasked with installing/uninstalling/maintaining VMA
- ISV partners who want to test/integrate their traffic-consuming/producing applications with VMA

2.1 Document Revision History

For the list of changes made to this document, refer to User Manual Revision History.
3 Release Notes

<table>
<thead>
<tr>
<th>Revision</th>

3.1.3 Certified Applications

The VMA library has been successfully tested and is certified to work with the applications listed in the following table.

<table>
<thead>
<tr>
<th>Application</th>
<th>Company / Source</th>
<th>Type</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>netperf</td>
<td>Open Source</td>
<td>Bandwidth and Latency Benchmarking</td>
<td>Version 2.6.0</td>
</tr>
<tr>
<td>NetPIPE</td>
<td>Open Source</td>
<td>Network Protocol Independent Performance Evaluator</td>
<td>Version 3.7.2</td>
</tr>
<tr>
<td>UMS (formerly LBM)</td>
<td>Informatica</td>
<td>Message Middleware Infrastructures</td>
<td>Version 6.7</td>
</tr>
</tbody>
</table>

3.2 Changes and New Features

3.2.1 Changes and New Features in this version

<table>
<thead>
<tr>
<th>Revision</th>
<th>Feature/Category</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.8.60</td>
<td>VMA Installation</td>
<td>New (Beta) method for VMA installation - See <a href="#">Installing VMA as DOCA Profile</a></td>
</tr>
<tr>
<td>9.8.60</td>
<td>Bug Fixes</td>
<td>See <a href="#">Bug Fixes in this Version</a> section.</td>
</tr>
</tbody>
</table>

3.2.2 Deprecated Features and Support

- As of VMA v9.0.2, VMA will no longer be backward compatible with MLNX_OFED versions earlier than v5.0-1.0.0.0
- Multi Packet Receive Queue beta functionality is removed as of VMA v9.3.1
- RDMA experimental verbs library (mlnx_lib)
- VMA v9.3.1 and up do not enforce the disable_raw_qp_enforcement option; use the CAP_NET_RAW option instead
- IPoIB is no longer supported with MLNX_OFED v5.1 and above

### 3.2.2.1 Important Notes

⚠️ We recommend using libnl3 as it is the latest version and includes fixes related to libnl1.

⚠️ Bonding Active-Backup (mode 1) is supported with limitations shown in Known Issues section.

### 3.3 Bug Fixes in this Version

For the list of older bug fixes, see Bug Fixes History.

<table>
<thead>
<tr>
<th>Internal Ref. Number</th>
<th>Details</th>
</tr>
</thead>
</table>
| 3749310              | **Description:** Compared to the kernel, the VMA is slower at sending the expected TCP keepAlive probes.  
**Keywords:** keepalive  
**Discovered in Version:** 9.8.51  
**Fixed in Version:** 9.8.60 |
| 3749337              | **Description:** VMA corresponds differently from the kernel when setting a TCP keepAlive timer to -1  
**Keywords:** keepalive  
**Discovered in Version:** 9.8.51  
**Fixed in Version:** 9.8.60 |

### 3.4 Known Issues

The following is a list of general existing limitations and known issues of the various components of VMA.

<table>
<thead>
<tr>
<th>Internal Reference Number</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>3876349</td>
<td><strong>Description:</strong> There is a risk of TX data corruption when over 16 application threads are involved in the following conditions: over 16 threads must be handling network sockets, the XLIO_RING_ALLOCATION_LOGIC_TX setting equals either 20 or 30, and there is a high traffic rate of packets smaller than 205 bytes.</td>
</tr>
<tr>
<td>Internal Reference Number</td>
<td>Details</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>
</tr>
</tbody>
</table>
|                           | **Workaround:** Either increase the number of BlueFlame registers with MLX5_TOTAL_UUARS env variable or disable BlueFlame doorbell method with MLX5_SHUT_UP_BF=1. Disabling BlueFlame will lead to a latency degradation.  
**Keywords:** multithreading, high concurrency, data corruption  
**Discovered In Version:** 9.8.60 |
| 3068120                   | **Description:** Multipath routing is not supported. A warning is printed if such a route is configured in the system. Note that traffic that is routed via a multipath route may be resent.  
**Workaround:** Covert multipath routes to a regular route with a single next hop.  
**Keywords:** ECMP; multipath routing  
**Discovered In Version:** 9.6.4 |
| 2371415                   | **Description:** In case the switch replicates a UDP packet for both ports, application will get a duplicated packet on a bonding interface.  
**Workaround:** N/A  
**Keywords:** RoCE LAG; Bonding  
**Discovered In Version:** 9.2.2 |
| 2394023                   | **Description:** Active-backup fail_over_mac = 1 mode is not be supported on bonding interface.  
**Workaround:** N/A  
**Keywords:** Bonding  
**Discovered In Version:** 9.2.2 |
| 2393571                   | **Description:** Detaching/attaching slaves on bond interface during runtime is not supported.  
**Workaround:** N/A  
**Keywords:** Bonding  
**Discovered In Version:** 9.2.2 |
| 1554637                   | **Description:** VMA offloads a NetVSC device (Windows Hyper-V network driver) only if SR-IOV is enabled upon application initialization.  
**Workaround:** N/A  
**Keywords:** Windows Hypervisor, NetVSC  
**Discovered In Version:** 8.7.5 |
| 1542628                   | **Description:** Device memory programming is not supported on VMs that lack Blue Flame support.  
**Workaround:** N/A  
**Keywords:** MEMIC, Device Memory, Virtual Machine, Blue flame  
**Discovered In Version:** 8.7.5 |
<table>
<thead>
<tr>
<th>Internal Reference Number</th>
<th>Details</th>
</tr>
</thead>
</table>
| **1262610** | **Description:** When working with Linux guest over Windows Hypervisor, and exceeding the maximum amount of flow steering rules supported by the VM, the following error message will appear:

```
VMA ERROR: rfs[0x32ea410]:273:create_ibv_flow() Create of QP flow ID (tag: 0) failed with flow dst: 5.5.7.689: src: 0.0.0.0, proto:UDP (errno=12 - Cannot allocate memory)
VMA ERROR: ring_simple[0x329a50]:555:attach_flow() attach_flow failed!
```

As a result, TCP Receive Flow will not be supported, and UDP Receive Flow will not be offloaded.

**Workaround:** Reduce the amount of supported VMs for the device in the Hypervisor to increase the total flow steering rules amount for each VM.

**Keywords:** Windows Hypervisor, flow steering limit

**Discovered in Version:** 8.5.7

| **1201675** | **Description:** When a non-privileged user uses VMA with RHEL inbox to perform networking operations (i.e. allocate IB resources) VMA crashes with a segmentation fault.

**Workaround:** Use VMA with root privileges on the RHEL inbox driver.

**Keywords:** RHEL inbox driver, segmentation fault

**Discovered in Version:** 8.4.10

| **965237** | **Description:** The following sockets APIs are directed to the OS and are not offloaded by VMA:
- `int socketpair(int domain, int type, int protocol, int sv[2]);`
- `int dup(int oldfd);`
- `int dup2(int oldfd, int newfd);`

**Workaround:** N/A

**Keywords:** sockets, socketpair, dup, dup2

**Discovered in Version:** 8.4.8

| **965227** | **Description:** Multicast (MC) loopback within a process is not supported by VMA:
- If an application process opens 2 (or more) sockets on the same MC group they will not get each other's traffic. **MC loopback between different VMA processes always work.**
- Both sockets will receive all ingress traffic coming from the wire

**Workaround:** N/A

**Keywords:** Multicast, Loopback

| **965227** | **Description:** Multicast (MC) loopback within a process is not supported by VMA:
- If an application process opens 2 (or more) sockets on the same MC group they will not get each other's traffic.

**Workaround:** N/A

**Keywords:** Multicast, Loopback
<table>
<thead>
<tr>
<th>Internal Reference Number</th>
<th>Details</th>
</tr>
</thead>
</table>
| 965227                    | **Description**: MC loopback between VMA and the OS limitation.  
  • The OS will reject loopback traffic coming from the NIC  
  • MC traffic from the OS to VMA is functional  
  **Workaround**: N/A  
  **Keywords**: Multicast, Loopback |
| 965227                    | **Description**: MC loopback Tx is currently disabled and setsockopt (IP_MULTICAST_LOOP) is not supported.  
  **Workaround**: N/A  
  **Keywords**: Multicast, Loopback |
| 919301                    | **Description**: VMA supports bonding in the following modes: 
  • For active-passive (mode=1), use either fail_over_mac=0 or fail_over_mac=1.  
  • For active-active (mode=4), use fail_over_mac=0.  
  • For VLAN over bond, use fail_over_mac=0 for traffic to be offloaded  
  **Workaround**: N/A  
  **Keywords**: High Availability (HA) |
| 1011005                   | **Description**: VMA SELECT option supports up to 200 sockets in TCP.  
  **Workaround**: Use ePoll that supports up to 6000 sockets.  
  **Keywords**: SockPerf |
| 977899                    | **Description**: An unsuccessful trial to connect to a local interface, is reported by VMA as Connection timeout rather that Connection refused.  
  **Workaround**: N/A  
  **Keywords**: Verification |
| 1019085                   | **Description**: Poll is limited with the amount of sockets.  
  **Workaround**: Use ePoll for large amount of sockets (tested up to 6000)  
  **Keywords**: Poll, ePoll |
| 2394023                  | **Description**: VLAN on the bond interface does not function properly when bonding is configured with fail_over_mac=1 due to a kernel bug.  
  **Workaround**: Set the fail_over_mac=0  
  **Keywords**: VLAN and High Availability (HA) |
|                          | **Description**: RX UDP UC and MC traffic in Ethernet with fragmented packages (message size is larger than MTU) is not offloaded by VMA and will pass through the Kernel network stack. There might be performance degradation.  
  **Workaround**: N/A  
  **Keywords**: Issues with UDP fragmented traffic reassembly |
|                          | **Description**: The following VMA_PANIC will be displayed when there are not enough open files defined on the server:  
  VMA PANIC : si[fd=1023][Si:sockinfo() failed to create internal epoll (ret=-1 Too many open files)] |
<table>
<thead>
<tr>
<th>Internal Reference Number</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Workaround:</strong> Verify that the number of max open FDs (File Descriptors) in the system (ulimit -n) is twice as number of needed sockets. VMA internal logic requires one additional FD per offloaded socket.</td>
<td></td>
</tr>
<tr>
<td><strong>Keywords:</strong> VMA_PANIC while opening large number of sockets</td>
<td></td>
</tr>
<tr>
<td><strong>Description:</strong> In MLNX_OFED versions earlier than v4.0-2.0.0.0 and VMA v8.2.10, socket API is only supported in the child process if the parent process has not called any socket routines prior to calling fork. In MLNX_OFED versions 4.0-1.6.1.0, VMA 8.2.10 and later the above restriction no longer exists however the child process cannot use any of the parent’s socket resources.</td>
<td></td>
</tr>
<tr>
<td><strong>Workaround:</strong> VMA supports fork() if VMA_FORK=1 (is enabled) and the Mellanox-supported stack OFED 4.0-1.6.1.0 or later is used. MLNX_OFED support for fork is for kernels supporting the MADV_DONTFORK flag for madvise() (2.6.17 and later), provided that the application does not use threads. The Posix system() call is supported.</td>
<td></td>
</tr>
<tr>
<td><strong>Keywords:</strong> There is limited support for fork().</td>
<td></td>
</tr>
<tr>
<td><strong>Description:</strong> Applications written in Java use IPv6 by default which is not supported by VMA and may lead to VMA not offloading packets</td>
<td></td>
</tr>
<tr>
<td><strong>Workaround:</strong> To change Java to work with IPv4, instruct the application to use “Java -Djava.net.preferIPv4Stack=true”</td>
<td></td>
</tr>
<tr>
<td><strong>Keywords:</strong> Java applications using IPv6 stack</td>
<td></td>
</tr>
<tr>
<td><strong>Description:</strong> When a VMA-enabled application is running, there are several cases when it does not exit as expected pressing CTRL-C.</td>
<td></td>
</tr>
<tr>
<td><strong>Workaround:</strong> Enable SIGINT handling in VMA, by using:</td>
<td></td>
</tr>
<tr>
<td>![](#export VMA_HANDLE_SIGINTR=1)</td>
<td></td>
</tr>
<tr>
<td><strong>Keywords:</strong> The VMA application does not exit when you press CTRL-C.</td>
<td></td>
</tr>
<tr>
<td><strong>Description:</strong> VMA does not support network interface or route changes during runtime</td>
<td></td>
</tr>
<tr>
<td><strong>Workaround:</strong> N/A</td>
<td></td>
</tr>
<tr>
<td><strong>Keywords:</strong> Dynamic route or IP changes</td>
<td></td>
</tr>
<tr>
<td><strong>Description:</strong> The send rate is higher than the receive rate. Therefore when running one sockperf server with one sockperf client there will be packets loss.</td>
<td></td>
</tr>
<tr>
<td>Internal Reference Number</td>
<td>Details</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------</td>

4 Introduction to VMA

4.1 VMA Overview

NVIDIA® Messaging Accelerator (VMA) library is a network-traffic offload, dynamically-linked userspace Linux library which serves to transparently enhance the performance of socket-based networking-heavy applications over an Ethernet network. VMA has been designed for latency-sensitive and throughput-demanding, unicast, and multicast applications. VMA can be used to accelerate producer applications and consumer applications and enhance application performance by orders of magnitude without requiring any modification to the application code.

The VMA library accelerates TCP and UDP socket applications, by offloading traffic from the userspace directly to the network interface card (NIC) or Host Channel Adapter (HCA), without going through the kernel and the standard IP stack (kernel-bypass). VMA increases overall traffic packet rate, reduces latency, and improves CPU utilization.

4.2 Basic Features

The VMA library utilizes the direct hardware access and advanced polling techniques of RDMA-capable network cards. Utilizing Ethernet’s direct hardware access enables the VMA kernel bypass, which causes the VMA library to bypass the kernel’s network stack for all IP network traffic transmit and receive socket API calls. Thus, applications using the VMA library gain many benefits, including:

- Reduced context switches and interrupts, which result in:
  - Lower latencies
  - Improved CPU utilization
- Minimal buffer copies between user data and hardware - VMA needs only a single copy to transfer a unicast or multicast offloaded packet between hardware and the application’s data buffers.

4.3 Target Applications

Good application candidates for VMA include, but are not limited to:

- Fast transaction-based network applications requiring a high rate of request-response type operations over TCP or UDP unicast, such as a Market Data Order Gateway application working with an exchange.
- Market-data feed-handler software that produces and consumes multicast data feeds, such as Wombat WDF and Reuters RMDS, or any home-grown feed handlers.
- Any other applications that make heavy use of multicast or unicast that require any combination of the following:
  - Higher Packets per Second (PPS) rates than with kernel
  - Lower data distribution latency
  - Lower CPU utilization by the multicast consuming/producing application in order to support further application scalability
4.4 Advanced VMA Features

The VMA library provides several significant advantages:

- The underlying wire protocol used for the unicast and multicast solution is standard TCP and UDP IPv4, which is interoperable with any TCP/UDP/IP networking stack. Thus, the opposite side of the communication can be any machine with any OS, and can be located on an Ethernet network.

  - VMA uses a standard protocol that enables an application to use the VMA for asymmetric acceleration purposes. A “TCP server side” only application, a “multicast consuming” only or “multicast publishing” only application can leverage this, while remaining compatible with Ethernet peers.

- Kernel bypass for unicast and multicast transmit and receive operations. This delivers much lower CPU overhead since TCP/IP stack overhead is not incurred.
- Reduced number of context switches. All VMA software is implemented in user space in the user application’s context. This allows the server to process a significantly higher packet rate than would otherwise be possible.
- Minimal buffer copies. Data is transferred from the hardware (NIC/HCA) straight to the application buffer in user space, with only a single intermediate user space buffer and zero kernel IO buffers.
- Fewer hardware interrupts for received/transmitted packets.
- Fewer queue congestion problems witnessed in standard TCP/IP applications.
- Supports legacy socket applications - no need for application code rewrite.
- Maximizes Messages per second (MPS) rates.
- Minimizes message latency.
- Reduces latency spikes (outliers).
- Lowers the CPU usage required to handle traffic.
5 VMA Library Architecture

5.1 Top-Level

The VMA library is a dynamically linked user-space library. Use of the VMA library does not require any code changes or recompiling of user applications. Instead, it is dynamically loaded via the Linux OS environment variable, LD_PRELOAD. However, it is possible to load VMA library dynamically without using the LD_PRELOAD parameter, which requires minor application modifications. Using VMA without code modification is described in Running VMA.

When a user application transmits TCP and UDP, unicast and multicast IPv4 data, or listens for such network traffic data, the VMA library:

- Intercepts the socket receive and send calls made to the stream socket or datagram socket address families.
- Implements the underlying work in user space (instead of allowing the buffers to pass on to the standard OS network kernel libraries).

VMA implements native RDMA verbs API. The native RDMA verbs have been extended into the Ethernet RDMA-capable NICs, enabling the packets to pass directly between the user application and the Ethernet NIC, bypassing the kernel and its TCP/UDP handling network stack.

You can implement the code in native RDMA verbs API, without making any changes to your applications. The VMA library does all the heavy lifting under the hood, while transparently presenting the same standard socket API to the application, thus redirecting the data flow.

The VMA library operates in a standard networking stack fashion to serve multiple network interfaces.

The VMA library behaves according to the way the application calls the bind, connect, and setsockopt directives and the administrator sets the route lookup to determine the interface to be used for the socket traffic. The library knows whether data is passing to or from an Ethernet NIC. If the data is passing to/from a supported HCA or Ethernet NIC, the VMA library does the bypass work. If the data is passing to/from an unsupported HCA or Ethernet NIC, the VMA library passes the call to the usual kernel libraries responsible for handling network traffic. Thus, the same application can listen in on multiple HCAs or Ethernet NICs, without requiring any configuration changes for the hybrid environment.

5.2 VMA Internal Thread

The VMA library has an internal thread which is responsible for performing general operations in order to maintain a high level of performance. These operations are performed in the context of a separate thread to that of the main application.

The main activities performed by the internal thread are:

- Poll the CQ if the application does not do so to avoid packet drops
- Synchronize the card clock with the system clock
- Handle any application housekeeping TCP connections (which should not impact its data path performance). For example: sending acknowledgements, retransmissions etc...
- Handle the final closing of TCP sockets
- Update VMA statistics tool data
- Update epoll file descriptor contexts for available non-offloaded data
- Handle bond management

There are several parameters by which the user can set the characteristics of the internal thread. See section VMA Configuration Parameters for a detailed description.

## 5.3 Socket Types

The following Internet socket types are supported:

- Datagram sockets, also known as connectionless sockets, which use User Datagram Protocol (UDP)
- Stream sockets, also known as connection-oriented sockets, which use Transmission Control Protocol (TCP)
6 VMA Installation

- Installing VMA
- Running VMA
- VMA Installation Options
- Uninstalling VMA
- Upgrading libvma.conf
- Port Type Management / VPI Cards Configuration
- Basic Performance Tuning

6.1 Installing VMA

Before you begin, verify you are using a supported operating system and a supported CPU architecture for your operating system. See supported combinations listed in System Requirements and Interoperability.

The current VMA version can work on top of both MLNX_OFED driver stack that supports Ethernet and on a lighter driver stack, MLNX_EN that supports only Ethernet.

The VMA library is delivered as a user-space library, and is called libvma.so.X.Y.Z.

VMA can be installed using one of the following methods:
- As part of NVIDIA® drivers (described on this page)
- Manually (see Installing the VMA Packages)
- Building the sources (see Building VMA From Sources)
- In RHEL 7.x Inbox (see Installing VMA in RHEL 7.x Inbox)
- Beta - As part of DOCA (see Installing VMA as DOCA profile)

6.1.1 Installing VMA Binary as Part of NVIDIA® Drivers

VMA is a part of the NVIDIA® drivers (MLNX_OFED/MLNX_EN) and it depends on the latest drivers, firmware, libraries, and kernel modules in the package. This installation assures VMA's correct functionality. The installation package has multiple supported distributions for RHEL, Ubuntu, and others. Pay attention to selecting the suitable distribution for your operating system.

This option suits user who want to install a new VMA version or upgrade to the latest VMA version by overriding the previous one.

6.1.2 NVIDIA® MLNX_OFED Driver for Linux

1. Download the latest MLNX_OFED driver from here.
2. Install the VMA packages.

```bash
./mlnxofedinstall --vma
```

3. Verify the installation completed successfully.

```
/etc/infiniband/info
```
6.1.3 NVIDIA® MLNX_EN Driver for Linux

1. Download the latest MLNX_EN driver from [here](#).
2. Install the VMA packages.

   ```
   ./install --vma
   ```
3. Verify the installation completed successfully.

   ```
   $ cat /etc/infiniband/info
   #!/bin/bash
   echo prefix=/usr
   echo Kernel=3.10.0-514.el7.x86_64
   echo
   echo
   ```

6.1.4 Starting the Drivers

1. Start the relevant driver (MLNX_OFED/MLNX_EN):

   ```
   /etc/init.d/openibd restart
   ```
   or

   ```
   systemctl restart openibd.service
   ```
2. Verify that the supported version of firmware is installed.

   ```
   ibv_devinfo
   ```

   **⚠️** To configure NVIDIA® ConnectX® adapter card ports to work with the desired transport, please refer to the section [Port Type Management/VPI Cards Configuration](#).

6.2 Running VMA

This section shows how to run a simple network benchmarking test and compare the kernel network stack results to VMA.

Before running a user application, you must set the library `libvma.so` into the environment variable `LD_PRELOAD`. For further information, please refer to the VMA User Manual.

Example:

```
$ LD_PRELOAD=libvma.so sockperf server -i 11.4.3.3
```
As a result, a VMA header message should precede your running application.

The output will always show:
- The VMA version
- The application’s name (in the above example: Cmd Line: sockperf sr)

The appearance of the VMA header indicates that the VMA library is loaded with your application.

6.2.1 Running VMA using non-root Permission

1. Check if the LD can find the libvma library.

```bash
ld -lvma -verbose
```

2. Set the UID bit to enforce user ownership.

```bash
sudo chmod u+s /usr/lib64/libvma*
```

```bash
sudo chmod u+s /sbin/sysctl
```

3. Grant **CAP_NET_RAW** privileges to the application.

```bash
sudo setcap cap_net_raw,cap_net_admin+ep /usr/bin/sockperf
```

4. Launch the application under no root.

```bash
LD_PRELOAD=libvma.so sockperf sr --tcp -i 10.0.0.4 -p 12345
LD_PRELOAD=libvma.so sockperf pp --tcp -i 10.0.0.4 -p 12345 -t10
```

6.2.2 Benchmarking Example

6.2.2.1 Prerequisites
- Install **sockperf** - a tool for network performance measurement
  - This can be done by either
    - Downloading and building from source from: [https://github.com/Mellanox/sockperf](https://github.com/Mellanox/sockperf)
    - Using

```bash
yum install: yum install sockperf
```

- Two machines, one serves as the server and the second as a client
  - Management interfaces configured with an IP that machines can ping each other
• Physical installation of an NVIDIA® NIC in your machines
  • Your system must recognize the NVIDIA® NIC. To verify it recognizes it, run:

```bash
lspci | grep Mellanox
```

Output example:

```bash
$ lspci | grep Mellanox
82:05.0 Ethernet controller: Mellanox Technologies MT28800 Family [ConnectX-5 Ex]  
82:08.1 Ethernet controller: Mellanox Technologies MT28800 Family [ConnectX-5 Ex]
```

6.2.2.2 Kernel Performance

6.2.2.2.1 Kernel Performance Server Side

On the first machine run:

```bash
$ sockperf server -i 11.4.3.3
```

Server side example output:

```bash
sockperf: [SERVER] listen on:sockperf: == version #3.7-no.git ==
sockperf: [SERVER] listen on:
[ 0 ] ID = 11.4.3.3  PORT = 11111 # UDP
sockperf: Warmup stage (sending a few dummy messages)...  
sockperf: [tid 124545] using recvfrom() to block on socket(s)
```

6.2.2.2.2 Kernel Performance Client Side

On the second machine run:

```bash
$ sockperf ping-pong -t 4 -i 11.4.3.3
```

Client-side example output:

```bash
sockperf: == version #3.7-no.git ==
sockperf[CLIENT] send on:sockperf: using recvfrom() to block on socket(s)
sockperf: [0] ID = 11.4.3.3  PORT = 11111 # UDP
sockperf: Warmup stage (sending a few dummy messages)...  
sockperf: Starting test...  
sockperf: Test end (interrupted by timer)
sockperf: Test ended
sockperf: [Total Run] RunTime=4.000 sec; Warm up time=400 msec; SentMessages=307425; ReceivedMessages=307424
sockperf: [Valid Duration] RunTime=3.550 sec; SentMessages=272899; ReceivedMessages=272899
sockperf: == avg-lat= 6.488 (std-dev=0.396)  
sockperf: # dropped messages = 0; # duplicated messages = 0; # out-of-order messages = 0
sockperf: Summary: Latency is 6.488 usec
sockperf: Total 272899 observations; each percentile contains 2728.99 observations
sockperf: ---> <MAX> observation = 20.484
sockperf: ---> percentile 99.999 = 17.732
sockperf: ---> percentile 99.999 = 9.364
sockperf: ---> percentile 99.900 = 8.491
sockperf: ---> percentile 99.000 = 7.963
sockperf: ---> percentile 90.000 = 6.975
sockperf: ---> percentile 75.000 = 6.831
sockperf: ---> percentile 50.000 = 6.307
sockperf: ---> percentile 25.000 = 6.212
sockperf: ---> <MIN> observation = 5.887
```
6.2.2.3 VMA Latency

Check the VMA performance by running sockperf and using the "VMA_SPEC=latency" environment variable.

6.2.2.3.1 VMA Performance Server Side

On the first machine run:

```
$ LD_PRELOAD=libvma.so VMA_SPEC=latency sockperf server -i 11.4.3.3
```

Server-side example output:

```
VMA INFO: VMA_VERSION: X.Y.Z-R Release built on MM DD YYYY HH:mm:ss

```
6.2.2.4 Comparing Results

VMA is showing over 614.3% performance improvement comparing to kernel

Average latency:
- Using Kernel 6.488 usec
- Using VMA 1.056 usec

Percentile latencies:

</tbody>
</table>

In order to tune your system and get best performance see section Basic Performance Tuning.

6.2.2.5 Libvma-debug.so

libvma.so is limited to DEBUG log level. In case it is required to run VMA with detailed logging higher than DEBUG level - use a library called libvma-debug.so that comes with OFED installation.
Before running your application, set the library libvma-debug.so into the environment variable LD_PRELOAD (instead of libvma.so).

Example:

```bash
$ LD_PRELOAD=libvma-debug.so sockperf server -i 11.4.3.3
```

**libvma-debug.so is located in the same library path as libvma.so under your distribution’s OS.**

For example in RHEL7.x x86_64, the libvma.so is located in /usr/lib64/libvma-debug.so.

NOTE: If you need to compile VMA with a log level higher than DEBUG run “configure” with the following parameter:

```
./configure --enable-opt-log=none
```

See section [Building VMA from Sources](#).

### 6.3 VMA Installation Options

#### 6.3.1 Installing VMA Binary Manually

VMA can be installed from a dedicated VMA RPM or a Debian package. In this case, please make sure that the MLXN Driver is already installed and that MLNX Driver and VMA versions match so that VMA functions correctly.

This option is suitable for users who receive an OEM VMA version, or a Fast Update Release VMA version which is newer than the installed VMA version.

#### 6.3.1.1 Installing the VMA Packages

This section addresses both RPM and DEB (Ubuntu OS) installations.

VMA includes the following packages which should be saved on your local drive:

- The libvma package contains the binary library shared object file (.so), configuration and documentation files
- The libvma-utils package contains utilities such as vma_stats to monitor vma traffic and statistics
- The libvma-devel package contains VMA’s extended API header files, for extra functionality not provided by the socket API

Before you begin, please verify the following prerequisites:

- Check whether VMA is installed:
  For RPM packages, run:
For DEB packages, run:

```
# apt-get remove libvma
```

**6.3.1.1.1 Installing the VMA Binary Package**

1. Go to the location where the libvma package was saved.
2. Run the command below to start installation:
   - For RPM packages:
     
     ```
     # rpm -i libvma-X.Y.Z-R.<arch>.rpm
     ```
   
   - For DEB packages:
     
     ```
     # dpkg -i libvma_X.Y.Z-R_<arch>.deb
     ```

During the installation process the:
- VMA library is copied to standard library location (e.g. `/usr/lib64/libvma.so`). In addition VMA debug library is copied under the same location (e.g. `/usr/lib64/libvma-debug.so`)
- README.txt and version information (VMA_VERSION) are installed at `/usr/share/doc/libvma-X.Y.Z/
- VMA installs its configuration file, `libvma.conf`, to the following location: `/etc/libvma.conf`
- The `vmad` service utility is copied into `/sbin`
- The script `vma` is installed under `/etc/init.d/`. This script can be used to load and unload the VMA service utility.

**6.3.1.1.2 Install the VMA utils Package**

1. Go to the location where the utils package was saved.
2. Run the command below to start installation:
   - For RPM packages:
     
     ```
     # rpm -i libvma-utils-X.Y.Z-R.<arch>.rpm
     ```
• For DEB packages:

#dpkg -i libvma-utils_X.Y.Z-R_<arch>.deb

During the installation process the VMA monitoring utility is installed at /usr/bin/vma_stats.

6.3.1.1.3 Installing the VMA devel Package
1. Go to the location where the devel package was saved.
2. Run the command below to start installation:
   • For RPM packages:

#rpm -i libvma-devel-X.Y.Z-R.<arch>.rpm

• For DEB packages:

#dpkg -i libvma-dev_X.Y.Z-R_<arch>.deb

During the installation process the VMA extra header file is installed at /usr/include/mellanox/vma_extra.h.

6.3.1.2 Verifying VMA Installation

For further information, please refer to Running VMA.

6.3.2 Building VMA From Sources

VMA as an open source enables users to try the code, inspect and modify. This option assumes that VMA (binary package) is already installed on top of NVIDIA® driver, and functions correctly (as explained in Installing the VMA Binary Package). Users can download the VMA sources from libvma GitHub and build a new VMA version. This option is suitable for users who wish to implement custom VMA modifications.

Please visit the libvma wiki page for various “how-to” issues.

For building VMA from sources, please visit the following page: https://github.com/Mellanox/libvma/wiki/Build-Instruction

For adding high debug log level to VMA compile it with:

./configure --enable-opt-log=none <other configure parameters>

For libvma configuration file please visit: https://github.com/Mellanox/libvma/wiki/VMA_Configuration_FILE.

6.3.2.1 Verifying VMA Compilation

The compiled VMA library is located under:

<path-to-vma-sources-root-tree>/src/vma/.libs/libvma.so
When running a user application, you must set the compiled library into the env variable LD_PRELOAD.

Example:

```
#LD_PRELOAD=/path-to-vma-sources-root-tree/src/vma/.libs/libvma.so sockperf ping-pong -t 5 -i 224.22.22.22
```

As indicated in section Running VMA, the appearance of the VMA header verifies that the compiled VMA library is loaded with your application.

Remark: it is recommended to keep the original libvma.so under the distribution’s original location (e.g. /usr/lib64/libvma.so) and not to override it with the newly compiled libvma.so.

### 6.3.3 Installing VMA in RHEL 7.x Inbox

⚠️ Please note, VMA can be installed in RHEL 7.2 and above Inbox Drivers.

RHEL 7.x distribution contains RoCE drivers version which can be retrieved by running “yum install”. The NVIDIA® drivers contain a code that was tested and integrated into the Linux upstream. However, this code may be either more or less advanced than MLNX_OFED version 4.0.x.x.x or MLNX-EN v3.4.x.x.x. In this case, you can:

This option is suitable for users who do not wish to change their exiting NVIDIA® driver that comes with RHEL 7.x installation.

RHEL 7.2 with Inbox drivers, please visit: [https://github.com/Mellanox/libvma/wiki/VMA-over-RHEL-7.x-with-inbox-driver](https://github.com/Mellanox/libvma/wiki/VMA-over-RHEL-7.x-with-inbox-driver).

For running VMA over RHEL 7.3 or later with Inbox drivers, execute:

```
yum install libvma
```

For libvma configuration file please visit: [https://github.com/Mellanox/libvma/wiki/VMA_Configuration_File](https://github.com/Mellanox/libvma/wiki/VMA_Configuration_File).

For information on how to uninstall VMA in RHEL 7.x Inbox, please refer to [VMA in RHEL 7.x Inbox Uninstallation](#).

⚠️ By default “yum install libvma” will install one of past VMA versions. In order to run with latest VMA version, you can compile libvma directly from GitHub.. For further information, refer to [Verifying VMA Compilation](#).

### 6.3.4 Installing VMA as DOCA Profile

⚠️ This feature is at beta level.

VMA can be installed from a dedicated VMA DOCA profile. In this case, please make sure to follow the [NVIDIA DOCA Installation Guide for Linux - NVIDIA Docs](#).
For VMA we have a dedicated DOCA profile “doca-vma”, the profile will install vma and all its dependencies.
To be able to use VMA there is no need to install any other doca profile except “doca-vma”.
Please follow the instructions for installing “doca-all” but replace it with “doca-vma”, for example:

```
sudo yum install -y doca-vma
```

### 6.4 Uninstalling VMA

#### 6.4.1 Automatic VMA Uninstallation

If you are about to install a new NVIDIA® driver version, the old VMA version will be automatically uninstalled as part of this process (followed by a new VMA version installation). Please refer to *Installing VMA Binary as Part of NVIDIA Drivers* for installing NVIDIA® drivers command details.

If you are about to uninstall the NVIDIA® Driver, VMA will be automatically uninstalled as part of this process.

#### 6.4.2 Manual VMA Uninstallation

If you are about to manually uninstall VMA packages, please run the following:

- For RPM packages:

  ```
  #rpm -e libvma-utils
  #rpm -e libvma-devel
  #rpm -e libvma
  ```

- For DEB packages:

  ```
  #dpkg -r libvma-utils
  #dpkg -r libvma-dev
  #dpkg -r libvma
  ```

When you uninstall VMA, the *libvma.conf* configuration file is saved with the existing configuration. The path of the saved path is displayed immediately after the uninstallation is complete.

#### 6.4.3 VMA in RHEL 7.x Inbox Uninstallation

VMA under RHEL 7.x is built from sources and is not installed as package. Therefore if VMA is not needed, delete the compiled libvma.so (or the entire libvma sources) and the configuration file (e.g. `/etc/libvma.conf`).

Note: Uninstalling RoCE drivers’ package using “yum remove” will neither delete the compiled VMA library nor the configuration file.

To uninstall VMA, run:

```
rpm -e libvma
```
6.5 Upgrading libvma.conf

When you upgrade VMA (through automatic or manual installation), the *libvma.conf* configuration file is handled as follows:

- If the existing configuration file has been modified since it was installed and is different from the upgraded RPM or DEB, the modified version will be left in place, and the version from the new RPM or DEB will be installed with a new suffix.
- If the existing configuration file has not been modified since it was installed, it will automatically be replaced by the version from the upgraded RPM or DEB.
- If the existing configuration file has been edited on disk, but is not actually different from the upgraded RPM or DEB, the edited version will be left in place; the version from the new RPM or DEB will not be installed.

6.6 Port Type Management / VPI Cards Configuration

NVIDIA® ConnectX®-5 ports can be individually configured to work as Ethernet ports. If you wish to change the port type, use the mlxconfig script after the driver is loaded.

For further information on how to set the port type, please refer to the MFT User Manual at [https://docs.nvidia.com/networking/category/mft](https://docs.nvidia.com/networking/category/mft).

6.7 Basic Performance Tuning

Please see the Tuning Guide and VMA Performance Tuning Guide for detailed instructions on how to optimally tune your machines for VMA performance.

6.7.1 VMA Tuning Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_SPEC</td>
<td>Optimized performance can easily be measured by VMA predefined specification</td>
<td>LD_PPRELOAD=libvma.so VMA_SPEC=latency sockperf ping-pong -t 10 -i 11.4.3.1</td>
</tr>
<tr>
<td></td>
<td>profile for latency:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Latency profile spec - optimized latency on all use cases. System is</td>
<td></td>
</tr>
<tr>
<td></td>
<td>tuned to keep balance between Kernel and VMA.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>▶️ It may limit the maximum bandwidth.</td>
<td></td>
</tr>
</tbody>
</table>
### 6.7.2 Binding VMA to the Closest NUMA

1. Check which NUMA is related to your interface.

```bash
cat /sys/class/net/<interface_name>/device/numa_node
```

Example:

```
[root@r-host142 ~]# cat /sys/class/net/ens5/device/numa_node
1
```

The output above shows that your device is installed next to NUMA 1.

2. Check which CPU is related to the specific NUMA.

```
[root@r-host144 ~]# lscpu
NUMA node0 CPU(s): 0-13,28-41
NUMA node1 CPU(s): 14-27,42-55
```

The output above shows that:

- CPUs 0-13 & 28-41 are related to NUMA 0
- CPUs 14-27 & 42-55 are related to NUMA 1

Since we want to use NUMA 1, one of the following CPUs should be used: 14-27 & 42-55

3. Use the "taskset" command to run the VMA process on a specific CPU.

   - Server side:

```bash
LD_PRELOAD=libvma.so taskset -c 15 sockperf sr -i 17.209.13.142
```

   - Client side:

```bash
VMA_RX_POLL=-1 LD_PRELOAD=libvma.so taskset -c 15 sockperf pp -i 17.209.13.142 -t 5
```

---

**Parameter** | **Description** | **Example**
---|---|---
VMA_RX_POL L | For blocking sockets only. It controls the number of times the ready packets can be polled on the RX path before they go to sleep (wait for interrupt in blocked mode). The recommended value for best latency is -1 (unlimited).
- For best latency, use -1 for infinite polling
- For low CPU usage use 1 for single poll
- Default value is 100000 | **Server:**
VMA_RX_POL L=-1 LD_PRELOAD=libvma.so taskset -c 15 sockperf sr -i 17.209.13.142

**Client:**
VMA_RX_POL L=-1 LD_PRELOAD=libvma.so taskset -c 15 sockperf pp -i 17.209.13.142 -t 5

VMA_INTERN AL_THREAD_AFFINITY | Controls which CPU core(s) the VMA internal thread is serviced on. The recommended configuration is to run VMA internal thread on a different core than the application but on the same NUMA node. | **Server:**
VMA_INTERNAL_THREAD_AFFINITY=14 VMA_RX_POL L=-1 LD_PRELOAD=libvma.so taskset -c 15 sockperf sr -i 17.209.13.142

**Client:**
VMA_INTERNAL_THREAD_AFFINITY=14 VMA_RX_POL L=-1 LD_PRELOAD=libvma.so taskset -c 15 sockperf pp -i 17.209.13.142 -t 5
In this example, we use CPU 15 that belongs to NUMA 1. You can also use "numactl - -hardware".

### 6.7.3 Configuring the BIOS

Each machine has its own BIOS parameters. It is important to implement any server manufacturer and Linux distribution tuning recommendations for lowest latency.

When configuring the BIOS, please pay attention to the following:

1. Enable Max performance mode.
2. Enable Turbo mode.
3. Power modes - disable C-states and P-states, do not let the CPU sleep on idle.
4. Hyperthreading - there is no right answer if you should have it ON or OFF.
   - ON means more CPU to handle kernel tasks, so the amortized cost will be smaller for each CPU
   - OFF means do not share cache with other CPUs, so cache utilization is better
   If all of your system jitter is under control, it is recommended to turn is OFF, if not keep it ON.
5. Disable SMI interrupts.
   - Look for "Processor Power and Utilization Monitoring" and "Memory Pre-Failure Notification" SMIs.
   - The OS is not aware of these interrupts, so the only way you might be able to notice them is by reading the CPU msr register.

Please make sure to carefully read your vendor BIOS tuning guide as the configuration options differ per vendor.
7 VMA Configuration

You can control the behavior of VMA by configuring:

- The `libvma.conf` file
- VMA configuration parameters, which are Linux OS environment variables
- VMA extra API

7.1 Configuring libvma.conf

The installation process creates a default configuration file, `/etc/libvma.conf`, in which you can define and change the following settings:

- The target applications or processes to which the configured control settings apply. By default, VMA control settings apply to all applications.
- The transport protocol to be used for the created sockets.
- The IP addresses and ports in which you want to offload.

By default, the configuration file allows VMA to offload everything except for the DNS server-side protocol (UDP, port 53) which will be handled by the OS.

In the `libvma.conf` file:

- You can define different VMA control statements for different processes in a single configuration file. Control statements are always applied to the preceding target process statement in the configuration file.
- Comments start with `#` and cause the entire line after it to be ignored.
- Any beginning whitespace is skipped.
- Any line that is empty is skipped.
- It is recommended to add comments when making configuration changes.

The following sections describe configuration options in `libvma.conf`. For a sample `libvma.conf` file, see Example of VMA Configuration.

7.1.1 Configuring Target Application or Process

The target process statement specifies the process to which all control statements that appear between this statement and the next target process statement apply.

Each statement specifies a matching rule that all its sub-expressions must evaluate as true (logical and) to apply.

If not provided (default), the statement matches all programs.

The format of the target process statement is:

```
application-id <program-name|*> <user-defined-id|> *
```
### 7.1.2 Configuring Socket Transport Control

Use socket control statements to specify when libvma will offload AF_INET/SOCK_STREAM or AF_INET/SOCK_DGRAM sockets (currently SOCK_RAW is not supported).

Each control statement specifies a matching rule that all its sub-expressions must evaluate as true (logical and) to apply. Statements are evaluated in order of definition according to "first-match".

Socket control statements use the following format:

```plaintext
use <transport> <role> <address>*:<port range>*
```

Where:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| **transport** | Define the mode of transport:  
- vma - VMA should be used.  
- os - the socket should be handled by the OS network stack. In this mode, the sockets are not offloaded. The default is vma. |
| **role** | Specify one of the following roles:  
- tcp_server - for listen sockets. Accepted sockets follow listen sockets. Defined by local_ip:local_port.  
- tcp_client - for connected sockets. Defined by remote_ip:remote_port:local_ip:local_port  
- udp_sender - for TX flows. Defined by remote_ip:remote_port  
- udp_receiver - for RX flows. Defined by local_ip:local_port  
- udp_connect - for UDP connected sockets. Defined by remote_ip:remote_port:local_ip:local_port |
| **address** | You can specify the local address the server is bind to or the remote server address the client connects to.  
The syntax for address matching is:  
- <IPv4 address>/[/<prefix_length>]*  
- IPv4 address - [0-9].[0-9]+\.[0-9]+\.[0-9]+ each sub number < 255  
- prefix_length - [0-9]+ and with value <= 32. A prefix_length of 24 # matches the subnet mask 255.255.255.0. A prefix_length of 32 requires matching of the exact IP. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>port range</td>
<td>Define the port range as:</td>
</tr>
<tr>
<td></td>
<td>start-port[-end-port]</td>
</tr>
<tr>
<td></td>
<td>Port range: 0-65536</td>
</tr>
</tbody>
</table>

### 7.1.3 Example of VMA Configuration

To set the following:

- Apply the rules to program `tcp_lat` with ID B1
- Use VMA by TCP clients connecting to machines that belong to subnet 192.168.1.*
- Use OS when TCP server listens to port 5001 of any machine

In *libvma.conf*, configure:

```bash
application-id tcp-lat B1
use vma tcp_client 192.168.1.0/24:*:*:
use os tcp_server *:5001
use os udp_connect *:53
```

You must also set the VMA parameter:

```bash
VMA_APPLICATION_ID=B1
```

### 7.2 VMA Configuration Parameters

VMA configuration parameters are Linux OS environment variables that are controlled with system environment variables.

It is recommended that you set these parameters prior to loading the application with VMA. You can set the parameters in a system file, which can be run manually or automatically.

All the parameters have defaults that can be modified.

On default startup, the VMA library prints the VMA version information, as well as the configuration parameters being used and their values to stderr.

VMA always logs the values of the following parameters, even when they are equal to the default value:

- VMA_TRACELEVEL
- VMA_LOG_FILE

For all other parameters, VMA logs the parameter values only when they are not equal to the default value.

The VMA version information, parameters, and values are subject to change.
### 7.2.1 Configuration Parameters Values

The following table lists the VMA configuration parameters and their possible values.

<table>
<thead>
<tr>
<th>VMA Configuration Parameter</th>
<th>Description and Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VMA_TRACELEVEL</strong></td>
<td></td>
</tr>
<tr>
<td>PANIC = 0</td>
<td>Panic level logging. This trace level causes fatal behavior and halts the application, typically caused by memory allocation problems. PANIC level is rarely used.</td>
</tr>
<tr>
<td>ERROR = 1</td>
<td>Runtime errors in VMA. Typically, this trace level assists you to identify internal logic errors, such as errors from underlying OS or InfiniBand verb calls, and internal double mapping/unmapping of objects.</td>
</tr>
<tr>
<td>WARN = WARNING = 2</td>
<td>Runtime warning that does not disrupt the application workflow. A warning may indicate problems in the setup or in the overall setup configuration. For example, address resolution failures (due to an incorrect routing setup configuration), corrupted IP packets in the receive path, or unsupported functions requested by the user application.</td>
</tr>
<tr>
<td>INFO = INFORMATION = 3</td>
<td>General information passed to the user of the application. This trace level includes configuration logging or general information to assist you with better use of the VMA library.</td>
</tr>
<tr>
<td>DETAILS</td>
<td>Greater general information passed to the user of the application. This trace level includes printing of all environment variables of VMA at start up.</td>
</tr>
<tr>
<td>VMA Configuration Parameter</td>
<td>Description and Examples</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>DEBUG = 4</td>
<td>High-level insight to the operations performed in VMA. In this logging level all socket API calls are logged, and internal high-level control channels log their activity.</td>
</tr>
<tr>
<td>FINE = FUNC = 5</td>
<td>Low-level runtime logging of activity. This logging level includes basic Tx and Rx logging in the fast path. Note that using this setting lowers application performance. We recommend that you use this level with the VMA_LOG_FILE parameter.</td>
</tr>
<tr>
<td>FINER = FUNC_ALL = 6</td>
<td>Very low-level runtime logging of activity. This logging level drastically lowers application performance. We recommend that you use this level with the VMA_LOG_FILE parameter.</td>
</tr>
<tr>
<td>VMA_LOG_DETAILS</td>
<td>Provides additional logging details on each log line. 0 = Basic log line 1 = With ThreadId 2 = With ProcessId and ThreadId 3 = With Time, ProcessId, and ThreadId (Time is the amount of milliseconds from the start of the process) Default: 0 For VMA_TRACELEVEL &gt;= 4, this value defaults to 2.</td>
</tr>
<tr>
<td>VMA_LOG_FILE</td>
<td>Redirects all VMA logging to a specific user-defined file. This is very useful when raising the VMA_TRACELEVEL. The VMA replaces a single '%d' appearing in the log file name with the pid of the process loaded with VMA. This can help when running multiple instances of VMA, each with its own log file name. Example: VMA_LOG_FILE=/tmp/vma_log.txt</td>
</tr>
<tr>
<td>VMA_CONFIG_FILE</td>
<td>Sets the full path to the VMA configuration file. Example: VMA_CONFIG_FILE=/tmp/libvma.conf Default: /etc/libvma.conf</td>
</tr>
<tr>
<td>LOG_COLORS</td>
<td>Uses a color scheme when logging; red for errors and warnings, and dim for very low level debugs. VMA_LOG_COLORS is automatically disabled when logging is done directly to a non-terminal device (for example, when VMA_LOG_FILE is configured). Default: 1 (Enabled)</td>
</tr>
<tr>
<td>VMA_CPU_USAGE_STATS</td>
<td>Calculates the VMA CPU usage during polling hardware loops. This information is available through VMA stats utility. Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA_APPLICATION_ID</td>
<td>Specifies a group of rules from libvma.conf for VMA to apply. Example: VMA_APPLICATION_ID=iperf_server Default: VMA_DEFAULT_APPLICATION_ID (match only the '*' group rule)</td>
</tr>
<tr>
<td>VMA_HANDLE_SIGINTR</td>
<td>When enabled, the VMA handler is called when an interrupt signal is sent to the process. VMA also calls the application’s handler, if it exists. Range: 0 to 1 Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA_HANDLE_SIGSEGV</td>
<td>When enabled, a print backtrace is performed, if a segmentation fault occurs. Range: 0 to 1 Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA Configuration Parameter</td>
<td>Description and Examples</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>VMA_STATS_FD_NUM</td>
<td>Maximum number of sockets monitored by the VMA statistics mechanism.</td>
</tr>
<tr>
<td></td>
<td>Range: 0 to 1024</td>
</tr>
<tr>
<td></td>
<td>Default: 100</td>
</tr>
<tr>
<td>VMA_STATS_FILE</td>
<td>Redirects socket statistics to a specific user-defined file.</td>
</tr>
<tr>
<td></td>
<td>VMA dumps each socket's statistics into a file when closing the socket.</td>
</tr>
<tr>
<td></td>
<td>Example: VMA_STATS_FILE=/tmp/stats</td>
</tr>
<tr>
<td>VMA_STATS_SHMEM_DIR</td>
<td>Sets the directory path for VMA to create the shared memory files for vma_stats.</td>
</tr>
<tr>
<td></td>
<td>If this value is set to an empty string: “”, no shared memory files are created.</td>
</tr>
<tr>
<td></td>
<td>Default: /tmp/</td>
</tr>
<tr>
<td>VMA_VMAD_NOTIFY_DIR</td>
<td>Sets the directory path for VMA to write files used by vmad.</td>
</tr>
<tr>
<td></td>
<td>Default value is /tmp/vma</td>
</tr>
<tr>
<td></td>
<td>Note: when used vmad must be run with --notify-dir directing the same folder.</td>
</tr>
<tr>
<td>VMA_TCP_MAX_SYN_RATE</td>
<td>Limits the number of TCP SYN packets that VMA handles per second for each listen socket.</td>
</tr>
<tr>
<td></td>
<td>Example: by setting this value to 10, the maximal number of TCP connection accepted by VMA per second for each listen socket will be 10.</td>
</tr>
<tr>
<td></td>
<td>Set this value to 0 for VMA to handle an unlimited number of TCP SYN packets per second for each listen socket.</td>
</tr>
<tr>
<td></td>
<td>Value range is 0 to 100000.</td>
</tr>
<tr>
<td></td>
<td>Default value is 0 (no limit)</td>
</tr>
<tr>
<td>VMA_TX_SEGS_TCP</td>
<td>Number of TCP LWIP segments allocation for each VMA process.</td>
</tr>
<tr>
<td></td>
<td>Default: 100000</td>
</tr>
<tr>
<td>VMA_TX_BUFS</td>
<td>Number of global Tx data buffer elements allocation.</td>
</tr>
<tr>
<td></td>
<td>Default: 200000</td>
</tr>
<tr>
<td>VMA_TX_WRE</td>
<td>Number of Work Request Elements allocated in all transmit QP's.</td>
</tr>
<tr>
<td></td>
<td>The number of QP's can change according to the number of network offloaded interfaces.</td>
</tr>
<tr>
<td></td>
<td>Default: 3000</td>
</tr>
<tr>
<td></td>
<td>The size of the Tx buffers is determined by the VMA_MTU parameter value (see below).</td>
</tr>
<tr>
<td></td>
<td>If this value is raised, the packet rate peaking can be better sustained; however, this increases memory usage. A smaller number of data buffers gives a smaller memory footprint, but may not sustain peaks in the data rate.</td>
</tr>
<tr>
<td>VMA_TX_WRE BATCHING</td>
<td>Controls the number of aggregated Work Requests Elements before receiving a completion signal (CQ entry) from the hardware.</td>
</tr>
<tr>
<td></td>
<td>Previously this number was hard coded as 64.</td>
</tr>
<tr>
<td></td>
<td>The new update allows a better control of the jitter encountered in the Tx completion handling.</td>
</tr>
<tr>
<td></td>
<td>Valid value range: 1-64</td>
</tr>
<tr>
<td></td>
<td>Default: 64</td>
</tr>
<tr>
<td>VMA_TX_MAX_INLINE</td>
<td>Max send inline data set for QP.</td>
</tr>
<tr>
<td></td>
<td>Data copied into the INLINE space is at least 32 bytes of headers and the rest can be user datagram payload.</td>
</tr>
<tr>
<td></td>
<td>VMA_TX_MAX_INLINE=0 disables INLINEing on the TX transmit path.</td>
</tr>
<tr>
<td></td>
<td>In older releases this parameter was called VMA_MAX_INLINE.</td>
</tr>
<tr>
<td></td>
<td>Default: 220</td>
</tr>
<tr>
<td>VMA Configuration Parameter</td>
<td>Description and Examples</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>VMA_TX_MC_LOOPBACK</td>
<td>Sets the initial value used internally by the VMA to control multicast loopback packet behavior during transmission. An application that calls setsockopt() with IP_MULTICAST_LOOP overwrites the initial value set by this parameter. Range: 0 - Disabled, 1 - Enabled Default: 1</td>
</tr>
<tr>
<td>VMA_TX_NONBLOCKED_EAGAIN</td>
<td>Returns value 'OK' on all send operations that are performed on a non-blocked udp socket. This is the OS default behavior. The datagram sent is silently dropped inside the VMA or the network stack. When set to Enabled (set to 1), VMA returns with error EAGAIN if it was unable to accomplish the send operation, and the datagram was dropped. In both cases, a dropped Tx statistical counter is incremented. Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA_TX_PREFETCH_BYTES</td>
<td>Accelerates an offloaded send operation by optimizing the cache. Different values give an optimized send rate on different machines. We recommend that you adjust this parameter to your specific hardware. Range: 0 to MTU size Disable with a value of 0 Default: 256 bytes</td>
</tr>
<tr>
<td>VMA_RX_BUFS</td>
<td>The number of Rx data buffer elements allocated for the processes. These data buffers are used by all QPs on all HCAs, as determined by the VMA_QP_LOGIC. Default: 200000</td>
</tr>
<tr>
<td>VMA_RX_WRE</td>
<td>The number of Work Request Elements allocated in all received QPs. Default: 16000</td>
</tr>
<tr>
<td>VMA_RX_WRE_BATCHING</td>
<td>Number of Work Request Elements and RX buffers to batch before recycling. Batching decreases the latency mean, but might increase latency STD. Valid value range: 1-1024 Default: 64</td>
</tr>
<tr>
<td>VMA_RX_BYTES_MIN</td>
<td>The minimum value in bytes used per socket by the VMA when applications call to setsockopt(SO_RCVBUF). If the application tries to set a smaller value than configured in VMA_RX_BYTES_MIN, VMA forces this minimum limit value on the socket. VMA offloaded sockets receive the maximum amount of ready bytes. If the application does not drain sockets and the byte limit is reached, newly received datagrams are dropped. The application's socket usage of current, max, dropped bytes and packet counters, can be monitored using vma_stats. Default: 65536</td>
</tr>
<tr>

<td>Description and Examples</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------</td>
</tr>
</tbody>
</table>
| **VMA_RX_POLL**             | The number of times to unsuccessfully poll an Rx for VMA packets before going to sleep. Range: -1, 0 ... 100,000,000 Default: 100,000 This value can be reduced to lower the load on the CPU. However, the price paid for this is that the Rx latency is expected to increase. Recommended values:  
  • 10000 - when CPU usage is not critical and Rx path latency is critical.  
  • 0 - when CPU usage is critical and Rx path latency is not critical.  
  • -1 - causes infinite polling. Once the VMA has gone to sleep, if it is in blocked mode, it waits for an interrupt; if it is in non-blocked mode, it returns -1. This Rx polling is performed when the application is working with direct blocked calls to read(), recv(), recvfrom(), and recvmsg(). When the Rx path has successful poll hits, the latency improves dramatically. However, this causes increased CPU utilization. For more information, see [Debugging, Troubleshooting, and Monitoring](#). |
| **VMA_RX_POLL_INIT**        | VMA maps all UDP sockets as potential Offloaded-capable. Only after ADD_MEMBERSHIP is set, the offload starts working and the CQ polling starts VMA. This parameter controls the polling count during this transition phase where the socket is a UDP unicast socket and no multicast addresses were added to it. Once the first ADD_MEMBERSHIP is called, the VMA_RX_POLL (above) takes effect. Value range is similar to the VMA_RX_POLL (above). Default: 0 |
| **VMA_RX_UDP_POLL_OS_RATIO**| Defines the ratio between VMA CQ poll and OS FD poll. This will result in a single poll of the not-offloaded sockets every VMA_RX_UDP_POLL_OS_RATIO offloaded socket (CQ) polls. No matter if the CQ poll was a hit or miss. No matter if the socket is blocking or non-blocking. When disabled, only offloaded sockets are polled. This parameter replaces the two old parameters:  
  • VMA_RX_POLL_OS_RATIO and  
  • VMA_RX_SKIP_OS  
  Disable with 0 Default: 10 |

<tbody>
<tr>
<td><strong>VMA_HW_TS_CONVERSION</strong></td>
<td>Defines timestamp conversion method.</td>
</tr>
<tr>
<td></td>
<td>The value of <strong>VMA_HW_TS_CONVERSION</strong> is determined by all devices, that is, if the hardware of one device does not support the conversion, then it will be disabled for the other devices. Currently only UDP RX flow is supported.</td>
</tr>
<tr>
<td></td>
<td>Options = [0, 1, 2, 3, 4]:</td>
</tr>
<tr>
<td></td>
<td>• 0 - Disabled</td>
</tr>
<tr>
<td></td>
<td>• 1 - Raw-HW time</td>
</tr>
<tr>
<td></td>
<td>Only convert the timestamp to seconds.nano_seconds time units (or disable if hardware does not supports).</td>
</tr>
<tr>
<td></td>
<td>• 2 - Best possible - Raw-HW or system time. Sync to system time, then Raw hardware time. Disable if none of them are supported by hardware.</td>
</tr>
<tr>
<td></td>
<td>• 3 - Sync to system time. Convert the timestamp to seconds.nano_seconds time units. Comparable to UDP receive software timestamp. Disable if hardware does not supports.</td>
</tr>
<tr>
<td></td>
<td>• 4 - PTP Sync</td>
</tr>
<tr>
<td></td>
<td>Convert the timestamp to seconds.nano_seconds time units. In case it is not supported - will apply option 3 (or disable if hardware does not supports).</td>
</tr>
<tr>
<td></td>
<td>Default value: 3 (Sync to system time)</td>
</tr>
<tr>
<td><strong>VMA_RX_POLL_YIELD</strong></td>
<td>When an application is running with multiple threads on a limited number of cores, there is a need for each thread polling inside VMA (read, ready, recv, and recvfrom) to yield the CPU to another polling thread so as not to starve them from processing incoming packets. Default: 0 (Disabled)</td>
</tr>
<tr>
<td><strong>VMA_RX_PREFETCH_BYTES</strong></td>
<td>The size of the receive buffer to prefetch into the cache while processing ingress packets. The default is a single cache line of 64 bytes which should be at least 32 bytes to cover the IPoIB+IP+UDP headers and a small part of the user payload. Increasing this size can help improve performance for larger user payloads. Range: 32 bytes to MTU size Default: 256 bytes</td>
</tr>
<tr>
<td><strong>VMA_RX_CQ_DRAIN_RATE_NSEC</strong></td>
<td>Socket’s receive path CQ drain logic rate control. When disabled (default), the socket’s receive path attempts to return a ready packet from the socket’s receive ready packet queue. If the ready receive packet queue is empty, the socket checks the CQ for ready completions for processing. When enabled, even if the socket’s receive ready packet queue is not empty, this parameter checks the CQ for ready completions for processing. This CQ polling rate is controlled in nanosecond resolution to prevent CPU consumption due to over CQ polling. This enables improved ‘real-time’ monitoring of the socket ready packet queue. Recommended value is 100-5000 (nsec) Default: 0 (Disabled)</td>
</tr>
<tr>
<td><strong>VMA_RX_POLL_ON_TX_TCP</strong></td>
<td>Enables TCP RX polling during TXP TX operation for faster TCP ACK reception Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA Configuration Parameter</td>
<td>Description and Examples</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>VMA_GRO_STREAMS_MAX</td>
<td>Controls the number of TCP streams to perform GRO (generic receive offload) simultaneously. Disable GRO with a value of 0. Default: 32</td>
</tr>
<tr>
<td>VMA_TCP_3T_RULES</td>
<td>Uses only 3 tuple rules for TCP, instead of using 5 tuple rules. This can improve performance for a server with a listen socket which accepts many connections from the same source IP. Enable with a value of 1. Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA_UDP_3T_RULES</td>
<td>This parameter is relevant in case the application uses connected UDP sockets. 3 tuple rules are used in hardware flow steering rule when the parameter is enabled, and in 5 tuple flow steering rule when it is disabled. Enabling this option can reduce hardware flow steering resources. However, when it is disabled, the application might see benefits in latency and cycles per packet. Default: 1 (Enable)</td>
</tr>
<tr>
<td>VMA_ETH_MC_L2_ONLY_RULES</td>
<td>Uses only L2 rules for Ethernet Multicast. All loopback traffic will be handled by VMA instead of OS. Enable with a value of 1. Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA_SELECT_POLL</td>
<td>The duration in micro-seconds (usec) in which to poll the hardware on Rx path before blocking for an interrupt (when waiting and also when calling select(), poll(), or epoll_wait()). Range: -1, 0 ... 100,000,000 Default: 100,000 When the selected path has successfully received poll hits, the latency improves dramatically. However, this comes at the expense of CPU utilization. For more information, see Debugging, Troubleshooting, and Monitoring.</td>
</tr>
<tr>
<td>VMA_SELECT_POLL_OS_RATIO</td>
<td>This enables polling the OS file descriptors while the user thread calls select(), poll(), or epoll_wait(), and VMA is busy in the offloaded socket polling loop. This results in a single poll of the non-offloaded sockets every VMA_SELECT_POLL_RATIOS offloaded socket (CQ) polls. When disabled, only offloaded sockets are polled. (See VMA_SELECT_POLL for more information.) Disable with 0 Default: 10</td>
</tr>
<tr>
<td>VMA_SELECT_SKIP_OS</td>
<td>In select(), poll(), or epoll_wait() forces the VMA to check the non-offloaded sockets even though an offloaded socket has a ready packet that was found while polling. Range: 0 ... 10,000 Default: 4</td>
</tr>
<tr>
<td>VMA_CQ_POLL_BATCH_MAX</td>
<td>The maximum size of the array while polling the CQs in the VMA. Default: 16</td>
</tr>
<tr>
<td>VMA_PROGRESS_ENGINE_INTERVAL</td>
<td>Internal VMA thread safety which checks that the CQ is drained at least once every N milliseconds. This mechanism allows VMA to progress the TCP stack even when the application does not access its socket (so it does not provide a context to VMA). If the CQ was already drained by the application receive socket API calls, this thread goes back to sleep without any processing. Disable with 0 Default: 10 milliseconds</td>
</tr>
<tr>
<td>VMA Configuration Parameter</td>
<td>Description and Examples</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>VMA_PROGRESS_ENGINE_WCE_MAX</td>
<td>Each time the VMA's internal thread starts its CQ draining, it stops when it reaches this maximum value. The application is not limited by this value in the number of CQ elements that it can ProcessId from calling any of the receive path socket APIs. Default: 2048</td>
</tr>
<tr>
<td>VMA_CQ_MODERATION_ENABLE</td>
<td>Enable CQ interrupt moderation. Default: 1 (Enabled)</td>
</tr>
<tr>
<td>VMA_CQ_MODERATION_COUNT</td>
<td>Number of packets to hold before generating interrupt. Default: 48</td>
</tr>
<tr>
<td>VMA_CQ_MODERATION_PERIOD_USEC</td>
<td>Period in microseconds for holding the packet before generating interrupt. Default: 50</td>
</tr>
<tr>
<td>VMA_CQ_AIM_MAX_COUNT</td>
<td>Maximum count value to use in the adaptive interrupt moderation algorithm. Default: 560</td>
</tr>
<tr>
<td>VMA_CQ_AIM_MAX_PERIOD_USEC</td>
<td>Maximum period value to use in the adaptive interrupt moderation algorithm. Default: 250</td>
</tr>
<tr>
<td>VMA_CQ_AIM_INTERVAL_MSEC</td>
<td>Frequency of interrupt moderation adaptation. Interval in milliseconds between adaptation attempts. Use value of 0 to disable adaptive interrupt moderation. Default: 250</td>
</tr>
<tr>
<td>VMA_CQ_AIM_INTERRUPTS_RATE_PER_SEC</td>
<td>Desired interrupts rate per second for each ring (CQ). The count and period parameters for CQ moderation will change automatically to achieve the desired interrupt rate for the current traffic rate. Default: 5000</td>
</tr>
<tr>
<td>VMA_CQ_KEEP_QP_FULL</td>
<td>If disabled (default), the CQ does not try to compensate for each poll on the receive path. It uses a “debt” to remember how many WRE are missing from each QP, so that it can fill it when buffers become available. If enabled, CQ tries to compensate QP for each polled receive completion. If there is a shortage of buffers, it reposts a recently completed buffer. This causes a packet drop, and is monitored in vma_stats. Default: 1 (Enabled)</td>
</tr>
<tr>
<td>VMA_QP_COMPENSATION_LEVEL</td>
<td>The number of spare receive buffer CQ holds that can be allowed for filling up QP while full receive buffers are being processed inside VMA. Default: 256 buffers</td>
</tr>
</tbody>
</table>
| VMA_OFFLOADED SOCKETS     | Creates all sockets as offloaded/not-offloaded by default.  
• 1 is used for offloaded  
• 0 is used for not-offloaded  
Default: 1 (Enabled) |
<p>| VMA_TIMER_RESOLUTION_MSEC | Control VMA internal thread wakeup timer resolution (in milliseconds). Default: 10 (milliseconds) |</p>
<table>
<thead>
<tr>
<th>VMA Configuration Parameter</th>
<th>Description and Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_TCP_TIMER_RESOLUTION_MSEC</td>
<td>Controls VMA internal TCP timer resolution (fast timer) (in milliseconds). Minimum value is the internal thread wakeup timer resolution (VMA_TIMER_RESOLUTION_MSEC). Default: 100 (milliseconds)</td>
</tr>
<tr>
<td>VMA_TCP_CTL_THREAD</td>
<td>Does all TCP control flows in the internal thread. This feature should be disabled if using blocking poll/select (epoll is OK). Use value of 0 to disable Use value of 1 to wake up the thread when there is work to be done Use value of 2 to wait for thread timer to expire Default: 0 (disabled)</td>
</tr>
<tr>
<td>VMA_TCP_TIMESTAMP_OPTION</td>
<td>Currently, LWIP is not supporting RTTM and PAWS mechanisms. See RFC1323 for info. Use value of 0 to disable (enabling causing a slight performance degradation of ~50-100 nano sec per half round trip) Use value of 1 for enable. Use value of 2 for OS follow up. Default: 0 (disabled)</td>
</tr>
<tr>
<td>VMA_TCP_NODELAY</td>
<td>If set, it disables the Nagle algorithm option for each TCP socket during initialization. Meaning that TCP segments are always sent as soon as possible, even if there is only a small amount of data. For more information on TCP_NODELAY flag refer to TCP manual page. Valid Values are: 0 to disable. 1 to enable (default)</td>
</tr>
<tr>
<td>VMA_TCP_QUICKACK</td>
<td>If set, it disables the delayed acknowledge ability. Meaning that TCP will respond after every packet. For more information on TCP_QUICKACK flag refer to TCP manual page. Valid Values are: 0 to disable. 1 to enable (default)</td>
</tr>
<tr>
<td>VMA_EXCEPTION_HANDLING</td>
<td>Handles missing support or error cases in Socket API or functionality by VMA. It quickly identifies VMA unsupported Socket API or features. Use value of -1 to handle DEBUG severity Use value of 0 to log DEBUG message and try recovering via Kernel network stack (un-offloading the socket) Use value of 1 to log ERROR message and try recovering via Kernel network stack (un-offloading the socket) Use value of 2 to log ERROR message and return API respectful error code Use value of 3 to log ERROR message and abort application (throw vma_error exception). Default: -1</td>
</tr>
<tr>
<td>VMA_AVOID_SYS_CALLS_ON_TCP_FD</td>
<td>For TCP fd, avoid system calls for the supported options of: ioctl, fcntl, getsockopt, setsockopt. Non-supported options will go to OS. To activate, use VMA_AVOID_SYS_CALLS_ON_TCP_FD=1. Default: 0 (disabled)</td>
</tr>
<tr>
<td>VMA Configuration Parameter</td>
<td>Description and Examples</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **VMA_THREAD_MODE**             | By default VMA is ready for multi-threaded applications, meaning it is thread-safe. If the user application is single threaded, use this configuration parameter to help eliminate VMA locks and improve performance. Values:  
• 0 - Single-threaded application  
• 1 - Multi-threaded application with spin lock  
• 2 - Multi-threaded application with mutex lock  
• 3 - Multi-threaded application with more threads than cores using spin lock  
Default: 1 (Multi with spin lock) |
| **VMA_BUFFER_BATCHING_MODE**    | Enables batching of returning Rx buffers and pulling Tx buffers per socket.  
• If the value is 0, then VMA will not use buffer batching  
• If the value is 1, then VMA will use buffer batching and will try to periodically reclaim unused buffers  
• If the value is 2, then VMA will use buffer batching with no reclaim  
Default: 1                                                                                                           |
| **VMA_MEM_ALLOC_TYPE**          | This replaces the VMA_HUGETBL parameter logic. VMA will try to allocate data buffers as configured:  
• 0 - "ANON" - using malloc  
• 1 - "CONTIG" - using contiguous pages  
• 2 - "HUGEPAGES" - using huge pages.  
OFED will also try to allocate QP & CQ memory accordingly:  
• 0 - "ANON" - default - use current pages ANON small ones.  
• "HUGE" - force huge pages  
• "CONTIG" - force contig pages  
• 1 - "PREFER_CONTIG" - try contig fallback to ANON small pages.  
• "PREFER_HUGE" - try huge fallback to ANON small pages.  
• 2 - "ALL" - try huge fallback to contig if failed fallback to ANON small pages.  
To override OFED use: (MLX_QP_ALLOC_TYPE, MLX_CQ_ALLOC_TYPE).  
Default: 1 (Contiguous pages) |
| **VMA_FORK**                    | Controls VMA fork support. Setting this flag on will cause VMA to call `ibv_fork_init()` function. `ibv_fork_init()` initializes `libibverbs`'s data structures to handle fork() function calls correctly and avoid data corruption.  
If `ibv_fork_init()` is not called or returns a non-zero status, then `libibverbs` data structures are not fork()-safe and the effect of an application calling `fork()` is undefined.  
`ibv_fork_init()` works on Linux kernels 2.6.17 and later, which support the MADV_DONTFORK flag for `madvise()`.  
You should use an OFED stack version that supports `fork()` with huge pages (MLNX_OFED 1.5.3 to 3.2 and 4.0-2.0.0.0 and later). VMA allocates huge pages (VMA_HUGETBL) by default.  
For limitations of using `fork()` with VMA, please refer to the Release Notes.  
Default: 1 (Enabled)               |
<table>
<thead>
<tr>
<th>VMA Configuration Parameter</th>
<th>Description and Examples</th>
</tr>
</thead>
</table>
| VMA_MTU                    | Size of each Rx and Tx data buffer (Maximum Transfer Unit). This value sets the fragmentation size of the packets sent by the VMA library.  
- If VMA_MTU is 0, then for each interface VMA will follow the actual MTU  
- If VMA_MTU is greater than 0, then this MTU value is applicable to all interfaces regardless of their actual MTU  
Default: 0 (following interface actual MTU) |
| VMA_MSS                    | Defines the max TCP payload size that can be sent without IP fragmentation. Value of 0 will set VMA's TCP MSS to be aligned with VMA_MTU configuration (leaving 40 bytes of room for IP + TCP headers; “TCP MSS = VMA_MTU - 40”). Other VMA_MSS values will force VMA's TCP MSS to that specific value. Default: 0 (following VMA_MTU) |
| VMA_CLOSE_ON_DUP2          | When this parameter is enabled, VMA handles the duplicated file descriptor (oldfd), as if it is closed (clear internal data structures) and only then forwards the call to the OS. This is, in effect, a very rudimentary dup2 support. It supports only the case where dup2 is used to close file descriptors. Default: 1 (Enabled) |
| VMA_INTERNAL_THREAD_AFFINITY | Controls which CPU core(s) the VMA internal thread is serviced on. The CPU set should be provided as either a hexadecimal value that represents a bitmask or as a comma delimited list of values (ranges are ok). Both the bitmask and comma delimited list methods are identical to what is supported by the taskset command. See the man page on taskset for additional information. The -1 value disables the Internal Thread Affinity setting by VMA.  
Bitmask examples: 0x00000001 – Run on processor 0  
0x00000007 – Run on processors 1,2, and 3  
Comma delimited examples: 0,4,8 – Run on processors 0,4, and 8  
0,1,7-10 – Run on processors 0,1,7,8,9 and 10  
Default: -1. |
<p>| VMA_INTERNAL_THREAD_CPUSET | Selects a CPUSET for VMA internal thread (For further information, see man page of cpuset). The value is either the path to the CPUSET (for example: /dev/cpuset/my_set), or an empty string to run it on the same CPUSET the process runs on. |
| VMA_INTERNAL THREAD ARM CQ  | Wakes up the internal thread for each packet that the CQ receives. Polls and processes the packet and brings it to the socket layer. This can minimize latency for a busy application that is not available to receive the packet when it arrives. However, this might decrease performance for high pps rate applications. Default: 0 (Disabled) |</p>
<table>
<thead>
<tr>
<th>VMA Configuration Parameter</th>
<th>Description and Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_INTERNAL_THREAD_TCP TIMER HANDLING</td>
<td>Selects the internal thread policy when handling TCP timers. Use value of 0 for deferred handling. The internal thread will not handle TCP timers upon timer expiration (once every 100ms) in order to let application threads handling it first. Use value of 1 for immediate handling. The internal thread will try locking and handling TCP timers upon timer expiration (once every 100ms). Application threads may be blocked till internal thread finishes handling TCP timers. Default value is 0 (deferred handling).</td>
</tr>
<tr>
<td>VMA_WAIT_AFTER_JOIN_MSEC</td>
<td>This parameter indicates the time of delay the first packet is send after receiving the multicast JOINED event from the SM. This is helpful to overcome loss of first few packets of an outgoing stream due to SM lengthy handling of MFT configuration on the switch chips. Default: 0 (milli-sec)</td>
</tr>
<tr>
<td>VMA_NEIGH_UC_ARP_QUATA</td>
<td>VMA will send UC ARP in case neigh state is NUD_STALE. If that neigh state is still NUD_STALE VMA will try VMA_NEIGH_UC_ARP_QUATA retries to send UC ARP again and then will send BC ARP. Default: 3</td>
</tr>
<tr>
<td>VMA_NEIGH_UC_ARP_DELAY_MSEC</td>
<td>This parameter indicates number of msec to wait between every UC ARP. Default: 10000</td>
</tr>
<tr>
<td>VMA_NEIGH_NUM_ERR_RETRIES</td>
<td>Indicates number of retries to restart NEIGH state machine if NEIGH receives ERROR event. Default: 1</td>
</tr>
<tr>
<td>VMA_BF</td>
<td>Enables/disables BlueFlame usage of the card. Default: 1 (Enabled)</td>
</tr>
<tr>
<td>VMA_SOCKETXTREME</td>
<td>When this parameter is enabled, VMA operates in SocketXtreme mode. SocketXtreme mode brings down latency, eliminating copy operations and increasing throughput, thus allowing applications to further utilize true kernel bypass architecture. An application should use a socket extension API named SocketXtreme. Default: 0 (Disabled)</td>
</tr>
<tr>
<td>VMA_TRIGGER_DUMMY_SEND_GETSOCKNAME</td>
<td>This parameter triggers dummy packet sent from getsockname() to warm up the caches. For more information see section &quot;Dummy Send&quot; to Improve Low Message Rate Latency. Default: 0 (Disable)</td>
</tr>
</tbody>
</table>
## VMA Configuration Parameter

<table>
<thead>
<tr>
<th>VMA Configuration Parameter</th>
<th>Description and Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_SPEC</td>
<td>VMA_SPEC sets all the required configuration parameters of VMA. Usually, no additional configuration is required.</td>
</tr>
</tbody>
</table>

VMA predefined specification profile for latency:
- latency - Latency profile spec - optimized latency on all use cases. System is tuned to keep balance between Kernel and VMA.

- multi_ring_latency - Multi ring latency spec - optimized for use cases that are keen on latency where two applications communicate using send-only and receive-only TCP sockets

Example: VMA_SPEC=latency
Example: VMA_SPEC=multi_ring_latency

### 7.2.2 Beta Level Features Configuration Parameters

The following table lists configuration parameters and their possible values for new VMA Beta level features. The parameters below are disabled by default.

These VMA features are still experimental and subject to changes. They can help improve performance of multithread applications.

We recommend altering these parameters in a controlled environment until reaching the best performance tuning.

<table>
<thead>
<tr>
<th>VMA Configuration Parameter</th>
<th>Description and Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_RING_ALLOCATION_LOGIC_TX</td>
<td>Ring allocation logic is used to separate the traffic into different rings. By default, all sockets use the same ring for both RX and TX over the same interface. For different interfaces, different rings are used, even when specifying the logic to be per socket or thread. Using different rings is useful when tuning for a multi-threaded application and aiming for HW resource separation.</td>
</tr>
<tr>
<td>VMA_RING_ALLOCATION_LOGIC_RX</td>
<td></td>
</tr>
</tbody>
</table>

This feature might decrease performance for applications which their main processing loop is based on select() and/or poll().

The logic options are:
- 0 - Ring per interface
- 1 - Ring per IP address (using IP address)
- 10 - Ring per socket (using socket ID as separator)
- 20 - Ring per thread (using the ID of the thread in which the socket was created)
- 30 - Ring per core (using CPU ID)
- 31 - Ring per core - attach threads: attach each thread to a CPU core

Default: 0
### VMA Configuration Parameter

<table>
<thead>
<tr>
<th>Description and Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VMA_RING_MIGRATION_RATIO_TX</strong>&lt;br&gt;<strong>VMA_RING_MIGRATION_RATIO_RX</strong></td>
</tr>
</tbody>
</table>

| **VMA_RING_LIMIT_PER_INTERFACE** | Limits the number of rings that can be allocated per interface. For example, in ring allocation per socket logic, if the number of sockets using the same interface is larger than the limit, several sockets will share the same ring. Use a value of 0 for an unlimited number of rings. Default: 0 (no limit) |

| **VMA_RING_DEV_MEM_TX** | VMA can use the on-device-memory to store the egress packet if it does not fit into the BF inline buffer. This improves application egress latency by reducing the PCI transactions. Using VMA_RING_DEV_MEM_TX, enables the user to set the amount of the on-device-memory buffer allocated for each TX ring. The total size of the on-device-memory is limited to 256k for a single port HCA and to 128k for dual port HCA. Default value is 0 |

| **VMA_TCP_CC_ALGO** | TCP congestion control algorithm. The default algorithm coming with LWIP is a variation of Reno/New-Reno. The new Cubic algorithm was adapted from FreeBsd implementation. Use value of 0 for LWIP algorithm. Use value of 1 for the Cubic algorithm. Use value of 2 in order to disable the congestion algorithm. Default: 0 (LWIP) |

---

### 7.3 Loading VMA Dynamically

VMA can be loaded using Dynamically Loaded (DL) libraries. These libraries are not automatically loaded at program link time or start-up as with LD_PRELOAD. Instead, there is an API for opening a library, looking up symbols, handling errors, and closing the library.

The example below demonstrates how to load socket() function. Similarly, users should load all other network-related functions as declared in `sock-redirect.h`:

```c
#include <stdlib.h>
#include <stdio.h>
#include <dlfcn.h>
#include <arpa/inet.h>
#include <sys/socket.h>
```
typedef int (*socket_fptr_t)(int __domain, int __type, int __protocol);
int main(int argc, const char** argv) {
    void* lib_handle;
    socket_fptr_t vma_socket;
    int fd;
    lib_handle = dlopen("libvma.so", RTLD_LAZY);
    if (!lib_handle) {
        printf("FAILED to load libvma.so\n");
        exit(1);
    }
    vma_socket = (socket_fptr_t)dlsym(lib_handle, "socket");
    if (vma_socket == NULL) {
        printf("FAILED to load socket\n");
        exit(1);
    }
    fd = vma_socket(AF_INET, SOCK_DGRAM, IPPROTO_UDP);
    if (fd < 0) {
        printf("FAILED open socket\n");
        exit(1);
    }
    printf("socket creation succeeded fd = %d\n", fd);
    close(fd);
    dlclose(lib_handle);
    return 0;
}

For more information, please refer to dlopen man page.

For a complete example that includes all the necessary functions, see sockperf’s vma-redirect.h and vma-redirect.cpp files.
8 Advanced Features

8.1 Packet Pacing

Packets transmitted over an offloaded socket may be rate-limited, thus, allowing granular rate control over the software defined flows. A rate-limited flow is allowed to transmit a few packets (burst) before its transmission rate is evaluated, and next packet is scheduled for transmission accordingly.

⚠️ This is a simple form of Packet Pacing supporting basic functionalities. For advanced Packing Pacing support and wide-range specification, please refer to Rivermax library.

8.1.1 Prerequisites

- MLNX_OFED version 4.1-x.x.x.x and above
- VMA supports packet pacing with NVIDIA® ConnectX®-5 devices.

If you have MLNX_OFED installed, you can verify whether your NIC supports packet pacing by running:

```
ibv_devinfo -v
```

Check the supported pace range under the section `packet_pacing_caps` (this range is in Kbit per second).

```
packet_pacing_caps:
gp_rate_limit_min:             1kbp/s
gp_rate_limit_max:             100000000kbp/s
```

8.1.2 Usage

Ø To apply Packet Pacing to a socket:

1. Run VMA with `VMA_RING_ALLOCATION_LOGIC_TX=10`.
2. Set the `SO_MAX_PACING_RATE` option for the socket:

```
uint32_t val = [rate in bytes per second];
setsockopt(fd, SOL_SOCKET, SO_MAX_PACING_RATE, &val, sizeof(val));
```

Notes:

- VMA converts the setsockopt value from bytes per second to Kbit per second.
- It is possible that the socket may be used over multiple NICs, some of which support Packet Pacing and some do not. Hence, setting the `SO_MAX_PACING_RATE` socket option does not guarantee that Packet Pacing will be applied.

In case of a failure when setting the packet pacing an error log will be printed to screen and no pacing will be done.
8.2 Precision Time Protocol (PTP)

VMA supports hardware timestamping for UDP-RX flow (only) with Precision Time Protocol (PTP).

When using VMA on a server running a PTP daemon, VMA can periodically query the kernel to obtain updated time conversion parameters which it uses in conjunction with the hardware time-stamp it receives from the NIC to provide synchronized time.

8.2.1 Prerequisites

- Support devices: HCA clock available (NVIDIA® ConnectX®-4 and above)
- Set VMA_HW_TS_CONVERSION environment variable to 4

8.2.2 Usage

1. Set the SO_TIMESTAMPING option for the socket with value SOF_TIMESTAMPING_RX_HARDWARE:

   ```c
   uint8_t val = SOF_TIMESTAMPING_RX_HARDWARE
   setsockopt(fd, SOL_SOCKET, SO_TIMESTAMPING, &val, sizeof(val));
   ```

2. Set VMA environment parameter VMA_HW_TS_CONVERSION to 4.

Example:

Use the Linux kernel (v4.11) timestamping example found in the kernel source at: tools/testing/selftests/networking/timestamping/timestamping.c.

Server

```bash
$ sudo LD_PRELOAD=libvma.so VMA_HW_TS_CONVERSION=4 ./timestamping <iface> SOF_TIMESTAMPING_RAW_HARDWARE
SOF_TIMESTAMPING_RX_HARDWARE
```

Client

```bash
$ LD_PRELOAD=libvma.so sockperf tp -i <server-ip> -t 3600 -p 6666 --mps 10
```

8.3 On-Device Memory

On-Device Memory is supported in ConnectX-5 adapter cards and above.

Each PCI transaction between the system’s RAM and NIC starts at ~300 nsec (and increasing depended on buffer size). Application egress latency can be improved by reducing as many PCI transition as possible on the send path.

Today, VMA achieves these goals by copying the WQE into the doorbell, and for small packets (<190 Bytes payload) VMA can inline the packet into the WQE and reduce the data gather PCI transition as well. For data sizes above 190 bytes, an additional PCI gather cycle by the NIC is required to pull the data buffer for egress.

VMA uses the on-device-memory to store the egress packet if it does not fit into the BF inline buffer. The on-device-memory is a resource managed by VMA and it is transparent to the user. The total
size of the on-device-memory is limited to 256k for a single port HCA and to 128k for dual port HCA. Using VMA_RING_DEV_MEM_TX, the user can set the amount of on-device-memory buffer allocated for each TX ring.

8.3.1 Prerequisites
- Driver: MLNX_OFED version 4.1-1.0.3.0.1 and above
- NIC: NVIDIA® ConnectX®-5 and above.
- Protocol: Ethernet.
- Set VMA_RING_DEV_MEM_TX environment variable to best suit the application's requirements

8.3.2 Verifying On-Device Memory Capability in the Hardware
To verify “On Device Memory” capability in the hardware, run VMA with DEBUG trace level:

```
VMA_TRACELEVEL=DEBUG LD_PRELOAD=<path to libvma.so> <command line>
```

Look in the printout for a positive value of on-device-memory bytes.

For example:
```
Pid: 30089 Tid: 30089 VMA DEBUG: ibch\[0xed61d0\]: print_val() mlx5_5: port(s): 1 vendor: 4121 fw: 16.23.0258
max_qp_wr: 32768 on_device_memory: 131072
```

To show and monitor On-Device Memory statistics, run vma_stats tool.

```
vma_stats -p <pid> -v 3
```

For example:
```
RING_ETH=[0]
Tx Offload: 858831 / 3402876 [kilobytes/packets]
Rx Offload: 865251 / 3402874 [kilobytes/packets]
Dev Mem Alloc: 16384
Dev Mem Stats: 735074 / 1784935 / 0 [kilobytes/packets/oob]
```

8.4 TCP_QUICKACK Threshold

⚠️ In order to enable TCP_QUICKACK threshold, the user should modify
TCP_QUICKACK_THRESHOLD parameter in the lwip/opt.h file and recompile VMA.

While TCP_QUICKACK option is enabled, TCP acknowledgments are sent immediately, rather than being delayed in accordance to a normal TCP receive operation. However, sending the TCP acknowledge delays the incoming packet processing to after the acknowledgement has been completed which can affect performance.

TCP_QUICKACK threshold enables the user to disable the quick acknowledgement for payloads that are larger than the threshold. The threshold is effective only when TCP_QUICKACK is enabled, using setsockopt() or using VMA_TCP_QUICKACK parameter. TCP_QUICKACK threshold is disabled by default.
8.5 Linux Guest over Windows Hypervisor

Network virtual service client (NetVSC) exposes a virtualized view of the physical network adapter on the guest operating system. NetVSC can be configured to connect to a Virtual Function (VF) of a physical network adapter that supports an SR-IOV interface.

VMA is able to offload the traffic of the NetVSC using the SR-IOV interface, only if the SR-IOV interface is available during the application initialization.

While the SR-IOV interface is detached, VMA is able to redirect/forward ingress/egress packets to/from the NetVSC - this is done using a dedicated TAP device for each NetVSC, in addition to traffic control rules.

VMA can detect plugin and plugout events during runtime and route the traffic according to the events’ type.

8.5.1 Prerequisites
- HCAs: NVIDIA® ConnectX®-5
- Operating systems:
  - Ubuntu 16.04, kernel 4.15.0-1015-azure
  - Ubuntu 18.04, kernel 4.15.0-1015-azure
  - RHEL 7.5, kernel 3.10.0-862.9.1.el7
- MLNX_OFED/Inbox driver: 4.5-x.x.x.x and above
- WinOF: v5.60 and above, WinOF-2: v2.10 and above
- Protocol: Ethernet
- Root/Net cap admin permissions
- VMA daemon enabled

8.5.2 VMA Daemon Design

VMA daemon is responsible for managing all traffic control logic of all VMA processes, including qdisc, u32 table hashing, adding filters, removing filters, removing filters when the application crashes.

For VMA daemon usage instructions, refer to the Installing the VMA Binary Package section in the Installation Guide.

For VMA daemon troubleshooting, see the Troubleshooting section.

8.5.3 TAP Statistics

To show and monitor TAP statistics, run the vma_stats tool:

```
vma_stats -p <pid> -v 3
```

Example:

```
RING_TAP=[0]
Master: D25964260
Tx Offload: 4463 / 67209 [kilobytes/packets]
```

58
Rx Offload: 5977 / 90013 [kilobytes/packets]
Rx Buffers: 256
VF Plugouts: 1
Tap fd: 21
Tap Device: td34f15

RING_ETH[1]
Master: 0x29e4260
Rx Offload: 5977 / 90013 [kilobytes/packets]
Rx Offload: 7527 / 113349 [kilobytes/packets]
Retransmissions: 1

Output analysis:
- RING_TAP[0] and RING_ETH[1] have the same bond master 0x29e4260
- 4463 Kbytes/67209 packets were sent from the TAP device
- 5977 Kbytes/90013 packets were received from the TAP device
- Plugout event occurred once
- TAP device fd number was 21, TAP name was td34f15
9 Using sockperf with VMA

Sockperf is VMA's sample application for testing latency and throughput over a socket API. The precompiled sockperf binary is located in /usr/bin/sockperf.

For detailed instructions on how to optimally tune your machines for VMA performance, please see the Tuning Guide and VMA Performance Tuning Guide.

To run a sockperf UDP test:

- To run the server, use:
  
  ```
  LD_PRELOAD=libvma.so sockperf sr -i <server ip>
  ```

- To run the client, use:
  
  ```
  LD_PRELOAD=libvma.so sockperf <sockperf test> -i <server ip>
  ```

Where:

- `<server ip>` is the IP address of the server
- `<sockperf test>` is the test you want to run, for example, `pp` for the ping-pong test, `tp` for the throughput test, and so on. (Use sockperf -h to display a list of all available tests.)

To run a sockperf TCP test:

- To run the server, use:
  
  ```
  LD_PRELOAD=libvma.so sockperf sr -i <server ip> --tcp
  ```

- To run the client, use:
  
  ```
  LD_PRELOAD=libvma.so sockperf <sockperf test> -i <server ip> --tcp
  ```

9.1 Example - Running sockperf Ping-pong Test

For optimal performance, please refer to Basic Performance Tuning.

1. Run sockperf server on Host A:

   ```
   LD_PRELOAD=libvma.so sockperf sr
   ```

2. Run sockperf client on Host B:

   ```
   LD_PRELOAD=libvma.so sockperf pp -i <server ip>
   ```
10 VMA Extra API

10.1 Overview of the VMA Extra API

The information in this chapter is intended for application developers who want to use VMA’s Extra API to maximize performance with VMA:

- To further lower latencies
- To increase throughput
- To gain additional CPU cycles for the application logic
- To better control VMA offload capabilities

All socket applications are limited to the given Socket API interface functions. The VMA Extra API enables VMA to open a new set of functions which allow the application developer to add code which utilizes zero copy receive function calls and low-level packet filtering by inspecting the incoming packet headers or packet payload at a very early stage in the processing.

VMA is designed as a dynamically-linked user-space library. As such, the VMA Extra API has been designed to allow the user to dynamically load VMA and to detect at runtime if the additional functionality described here is available or not. The application is still able to run over the general socket library without VMA loaded as it did previously, or can use an application flag to decide which API to use: Socket API or VMA Extra API.

The VMA Extra APIs are provided as a header with the VMA binary rpm. The application developer needs to include this header file in his application code.

After installing the VMA rpm on the target host, the VMA Extra APIs header file is located in the following link:

```c
#include "/usr/include/mellanox/vma_extra.h"
```

The vma_extra.h provides detailed information about the various functions and structures, and instructions on how to use them.

An example using the VMA Extra API can be seen in the udp_lat source code:

- Follow the ‘--vmarxfiltercb’ flag for the packet filter logic
- Follow the ‘--vmazcopyread’ flag for the zero copy recvfrom logic

A specific example for using the TCP zero copy extra API can be seen under extra_api_tests/tcp_zcopy_cb.

10.2 Using VMA Extra API

During runtime, use the vma_get_api() function to check if VMA is loaded in your application, and if the VMA Extra API is accessible.

If the function returns with NULL, either VMA is not loaded with the application, or the VMA Extra API is not compatible with the header function used for compiling your application. NULL will be the typical return value when running the application on native OS without VMA loaded.

Any non-NULL return value is a vma_api_t type structure pointer that holds pointers to the specific VMA Extra API function calls which are needed for the application to use.
It is recommended to call vma_get_api() once on startup, and to use the returned pointer throughout the life of the process.

There is no need to ‘release’ this pointer in any way.

10.3 Control Off-load Capabilities During Run-Time

10.3.1 Adding libvma.conf Rules During Run-Time

Adds a libvma.conf rule to the top of the list. This rule will not apply to existing sockets which already considered the conf rules. (around connect/listen/send/recv ..)

Syntax:

```c
int (*add_conf_rule)(char *config_line);
```

Return value:

- 0 on success
- error code on failure

Where:

- config_line
  - Description - new rule to add to the top of the list (highest priority)
  - Value - a char buffer with the exact format as defined in libvma.conf, and should end with '\0'

10.3.2 Creating Sockets as Offloaded or Not-Offloaded

Creates sockets on pthread tid as off-loaded/not-off-loaded. This does not affect existing sockets. Offloaded sockets are still subject to libvma.conf rules.

Usually combined with the VMA_OFFLOADED_SOCKETS parameter.

Syntax:

```c
int (*thread_offload)(int offload, pthread_t tid);
```

Return value:

- 0 on success
- error code on failure

Where:

- offload
  - Description - Offload property
  - Value - 1 for offloaded, 0 for not-offloaded
- tid
  - Description - thread ID
10.4 Packet Filtering

The packet filter logic gives the application developer the capability to inspect a received packet. You can then decide, on the fly, to keep or drop the received packet at this stage in processing.

The user’s application packet filtering callback is defined by the prototype:

```c
typedef vma_recv_callback_retval_t (*vma_recv_callback_t) (int fd, size_t sz_iov, struct iovec iov[], struct vma_info_t* vma_info, void *context);
```

This callback function should be registered with VMA by calling the VMA Extra API function `register_recv_callback()`. It can be unregistered by setting a NULL function pointer.

VMA calls the callback to notify of new incoming packets after the internal IP & UDP/TCP header processing, and before they are queued in the socket’s receive queue.

The context of the callback is always that of one of the user’s application threads that called one of the following socket APIs: `select()`, `poll()`, `epoll_wait()`, `recv()`, `recvfrom()`, `recvmsg()`, `read()`, or `readv()`.

### Packet Filtering Callback Function

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd</td>
<td>File descriptor of the socket to which this packet refers.</td>
</tr>
<tr>
<td>iov</td>
<td>iovec structure array pointer holding the packet received, data buffer pointers, and the size of each buffer.</td>
</tr>
<tr>
<td>iov_sz</td>
<td>Size of the iov array.</td>
</tr>
<tr>
<td>vma_info</td>
<td>Additional information on the packet and socket.</td>
</tr>
<tr>
<td>context</td>
<td>User-defined value provided during callback registration for each socket.</td>
</tr>
</tbody>
</table>

⚠️ The application can call all the Socket APIs from within the callback context.

Packet loss might occur depending on the application's behavior in the callback context. A very quick non-blocked callback behavior is not expected to induce packet loss.

Parameters the “iov” and “vma_info” are only valid until the callback context is returned to VMA. You should copy these structures for later use, if working with zero copy logic.

10.4.1 Zero Copy recvfrom()

Zero-copy recvfrom implementation. This function attempts to receive a packet without doing data copy.

Syntax:

```c
int (*recvfrom_zcopy)(int s, void *buf, size_t len, int *flags, struct sockaddr *from, socklen_t *fromlen);
```
Where:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>Socket file descriptor</td>
<td></td>
</tr>
<tr>
<td>buf</td>
<td>Buffer to fill with received data or pointers to data (see below).</td>
<td></td>
</tr>
<tr>
<td>flags</td>
<td>Pointer to flags (see below).</td>
<td>MSG_VMA_ZCOPY_FORCE</td>
</tr>
<tr>
<td>from</td>
<td>If not NULL, is set to the source address (same as recvfrom)</td>
<td></td>
</tr>
<tr>
<td>fromlen</td>
<td>If not NULL, is set to the source address size (same as recvfrom).</td>
<td></td>
</tr>
</tbody>
</table>

The flags parameter can contain the usual flags to recvmsg(), and also the MSG_VMA_ZCOPY_FORCE flag. If the latter is not set, the function reverts to data copy (i.e., zero-copy cannot be performed). If zero-copy is performed, the flag MSG_VMA_ZCOPY is set upon exit.

If zero copy is performed (MSG_VMA_ZCOPY flag is returned), the buffer is filled with a vma_packets_t structure holding as much fragments as ‘len’ allows. The total size of all fragments is returned. Otherwise, the buffer is filled with actual data, and its size is returned (same as recvfrom()).

If the return value is positive, data copy has been performed. If the return value is zero, no data has been received.

### 10.4.2 Freeing Zero Copied Packet Buffers

Frees a packet received by "recvfrom_zcopy()" or held by "receive callback".

**Syntax:**

```c
int (*free_packets)(int s, struct vma_packet_t *pkts, size_t count);
```

**Where:**

- s - socket from which the packet was received
- pkts - array of packet identifiers
- count - number of packets in the array

**Return value:**

- 0 on success, -1 on failure
- errno is set to:
  - EINVAL - not a VMA offloaded socket
  - ENOENT - the packet was not received from ‘s’

**Example:**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tx total byte</td>
<td>The number of transmit bytes (from InfiniBand-to-Ethernet) associated with a TFM rule; has a log counter n.</td>
</tr>
<tr>
<td></td>
<td>The above example shows the number of bytes sent from Infiniband to Ethernet (one way) or sent between InfiniBand and Ethernet and matching the two TFM rules with log counter #1.</td>
</tr>
<tr>
<td>rx total pack</td>
<td>The number of receive packets (from Ethernet to InfiniBand) associated with a TFM rule; has a log counter n.</td>
</tr>
<tr>
<td>rx total byte</td>
<td>The number of receive bytes (from Ethernet to InfiniBand) associated with a TFM rule; has a log counter n.</td>
</tr>
</tbody>
</table>

### 10.5 Dump fd Statistics using VMA Logger

Dumps statistics for fd number using log_level log level.

**Syntax:**

```c
int (*dump_fd_stats) (int fd, int log_level);
```

**Parameters:**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fd</td>
<td>fd to dump, 0 for all open fds.</td>
</tr>
</tbody>
</table>
| log_level   | log_level dumping level corresponding vlog_levels_t enum (vlogger.h):
|             | VLOG_NONE = -1
|             | VLOG_PANIC = 0
|             | VLOG_ERROR = 1
|             | VLOG_WARNING = 2
|             | VLOG_INFO = 3
|             | VLOG_DETAILS = 4
|             | VLOG_DEBUG = 5
|             | VLOG_FUNC = VLOG_FINE = 6
|             | VLOG_FUNC_ALL = VLOG_FINER = 7
|             | VLOG_ALL = 8

For output example see section Monitoring - the vma_stats Utility. Return values: 0 on success, -1 on failure
10.6 "Dummy Send" to Improve Low Message Rate Latency

The “Dummy Send” feature gives the application developer the capability to send dummy packets in order to warm up the CPU caches on VMA send path, hence minimizing any cache misses and improving latency. The dummy packets reaches the hardware NIC and then is dropped.

The application developer is responsible for sending the dummy packets by setting the VMA_SND_FLAGS_DUMMY bit in the flags parameter of send(), sendto(), sendmsg(), and sendmmsg() sockets API.

Parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_SND_FLAGS_DUMMY</td>
<td>Indicates a dummy packet</td>
</tr>
</tbody>
</table>

Same as the original APIs for offloaded sockets. Otherwise, -1 is returned and errno is set to EINVAL. Return values:

Usage example:

```c
void dummyWait(Timer waitDuration, Timer dummySendCycleDuration) {
    Timer now = Timer::now();
    Timer endTime = now + waitDuration;
    Timer nextDummySendTime = now + dummySendCycleDuration;
    for (; now < endTime; now = Timer::now()) {
        if (now >= nextDummySendTime) {
            send(fd, buf, len, VMA_SND_FLAGS_DUMMY);
            nextDummySendTime += dummySendCycleDuration;
        }
    }
}
```

This sample code consistently sends dummy packets every `DummysendCycleDuration` using the VMA extra API while the total time does not exceed `waitDuration`.

It is recommended not to send more than 50k dummy packets per second.

10.6.1 Verifying “Dummy Send” capability in HW

“Dummy Send” feature is supported in hardware starting from ConnectX-4 NIC.

In order to verify “Dummy Send” capability in the hardware, run VMA with DEBUG trace level.

```
VMA_TRACELEVEL=DEBUG LD_PRELOAD=path to libvma.so <command line>
```

Look in the printout for “HW Dummy send support for QP = [0|1]”.

For example:

```
Pid: 3832 Tid: 3832 VMA DEBUG: qge[0x2097310]:121:configure() Creating QP of transport type 'ETH' on ibv device 'mlx5_0 [0x201e460] on port 1 Pid: 3832 Tid: 3832 VMA DEBUG: qge[0x2097310]:137:configure() HW Dummy send support for QP = 1 Pid: 3832 Tid: 3832 VMA DEBUG: cqm[0x203a460]:269: cq_mgr() Created CQ as Tx with fd[25] and of size 3000 elements (ibv_cq_hndl=0x20a0000)
```
10.6.2 “Dummy Packets” Statistics

Run `vma_stats` tool to view the total amount of dummy-packets sent.

```
vma_stats -p <pid> -v 3
```

The number of dummy messages sent will appear under the relevant fd. For example:

```
====================================================== Fd=[20] - UDP, Blocked, MC Loop Enabled - Local Address = [0 .0.0.0:56732] Tx Offload: 128 / 9413 / 0 / 0 [kilobytes/packets/drops/errors] Tx Dummy messages : 87798 Rx Offload: 128 / 9413 / 0 / 0 [kilobytes/packets/eagains/errors] Rx byte: cur b / max 14 / dropped 0 / limit 212992 Rx pkt : cur 0 / max 1 / dropped 0 / limit 1411 (100.00%) [miss/hit]
======================================================
```

10.7 SocketXtreme

⚠️ Starting from VMA v8.5.x, `VMA_POLL` parameter is renamed to `SocketXtreme`.

The API introduced for this capability allows an application to remove the overhead of socket API from the receive flow data path, while keeping the well-known socket API for the control interface. Using such functionality the application has almost direct access to VMA’s HW ring object and it is possible to implement a design which does not call socket APIs such as `select()`, `poll()`, `epoll_wait()`, `recv()`, `recvfrom()`, `recvmsg()`, `read()`, or `readv()`.

The structures and constants are defined as shown below.

**VMA Specific Events**

```c
typedef enum { VMA_SOCKETXTREME_PACKET = (1ULL << 32), VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED = (1ULL << 33) } vma_socketxtreme_events_t;
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMA_SOCKETXTREME_PACKET</td>
<td>New packet is available</td>
</tr>
<tr>
<td>VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED</td>
<td>New connection is auto accepted by server</td>
</tr>
</tbody>
</table>

10.7.1 VMA Buffer

```c
struct vma_buff_t { struct vma_buff_t* next; void* payload; uint16_t len; };
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>next</td>
<td>Next buffer (for last buffer next == NULL)</td>
</tr>
<tr>
<td>payload</td>
<td>Point to data</td>
</tr>
<tr>
<td>len</td>
<td>Data length</td>
</tr>
</tbody>
</table>
struct vma_packet_desc_t { size_t num_bufs; uint16_t total_len; struct vma_buff_t* buff_lst; };

VMA Packet

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>total_len</td>
<td>Total data length</td>
</tr>
<tr>
<td>buff_lst</td>
<td>List of packet’s buffers</td>
</tr>
<tr>
<td>len</td>
<td>Data length</td>
</tr>
</tbody>
</table>

struct vma_completion_t { struct vma_packet_desc_t packet; uint64_t events; uint64_t user_data; struct sockaddr_in src; int listen_fd; };

10.7.2 Polling for VMA Completions

Syntax:

```c
int (*socketxtreme_poll)(int fd, struct vma_completion_t* completions, unsigned int ncompletions, int flags);
```

Where:
- fd - file descriptor
- completions - array of completion elements
- ncompletions - number of elements in passed array
- flags - flags to control behavior (set zero)

Return values: Returns the number of ready completions during success. A negative value is returned in case of failure.

Description: This function polls the `fd` for VMA completions and returns maximum `ncompletions` - ready completions via the `completions` array. The `fd` represents a ring file descriptor. VMA completions are indicated for incoming packets and/or for other events. If VMA_SOCKETXTREME_PACKET flag is enabled in the vma_completion_t.events field the completion
points to the incoming packet descriptor that can be accessed via the vma_completion_t.packet field. Packet descriptor points to the VMA buffers that contain data scattered by HW, so the data is delivered to the application with zero copy. Notice: after the application is finished with the returned packets and their buffers it must free them using free_vma_packets()/free_vma_buff() functions. If VMA_SOCKETXTREME_PACKET flag is disabled vma_completion_t.packet field is reserved. In addition to packet arrival event (indicated by VMA_SOCKETXTREME_PACKET flag) VMA also reports VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED event and standard epoll events via the vma_completion_t.events field. VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED event is reported when new connection is accepted by the server. When working with socketxtreme_poll() new connections are accepted automatically and accept (listen_socket) must not be called. VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED event is reported for the new connected/child socket (vma_completion_t.user_data refers to child socket) and EPOLLIN event is not generated for the listen socket. For events other than packet arrival and new connection acceptance vma_completion_t.events bitmask composed using standard epoll API events types. Notice: the same completion can report multiple events, for example VMA_SOCKETXTREME_PACKET flag can be enabled together with EPOLLOUT event, etc.

10.7.3 Getting Number of Attached Rings

Syntax:

```c
int (*get_socket_rings_num)(int fd);
```

Where:

- `fd` - file descriptor

Return values: Returns the number of rings during success. A negative value is returned in case of failure.

Description: Returns the number of rings that are associated with the socket.

10.7.4 Getting Ring FD

Syntax:

```c
int (*get_socket_rings_fds)(int fd, int *ring_fds, int ring_fds_sz);
```

Where:

- `fd` - file descriptor
- `ring_fds` - int array of ring fds
- `ring_fds_sz` - size of the array

Return values: Returns the number populated array entries during success. A negative value is returned in case of failure.

Description: Returns FDs of the rings that are associated with the socket.

10.7.5 Free VMA Packets

Syntax:
int (*socketxtreme_free_vma_packets)(struct vma_packet_desc_t *packets, int num);

Where:
- packets - packets to be freed
- num - number of packets in passed array

Return values: Returns zero value during success. A negative value is returned in case failure.

Description: Frees packets received by socketxtreme_poll().

For each packet in the `packets` array this function updates the receive queue size and the advertised TCP window size, if needed, for the socket that received the packet and frees VMA buffer list that is associated with the packet. Notice: for each buffer in the buffer list VMA decreases buffer's ref count and only buffers with ref count zero are deallocated. An application can call socketxtreme_ref_vma_buf() to increase the buffer reference count in order to hold the buffer even after socketxtreme_free_vma_packets() has been called. Also, the application is responsible to free buffers that could not be deallocated during socketxtreme_free_vma_packets() due to non-zero reference count. This is done by calling the socketxtreme_free_vma_buff() function.

### 10.7.6 Decrement VMA Buffer Reference Counter

Syntax:

```c
int (*socketxtreme_free_vma_buff)(struct vma_buff_t *buff);
```

Return values: Returns the buffer's reference count after the change (zero value means that the buffer has been deallocated). A negative value is returned in case of failure.

Description: Decrement the reference counter of a buffer received by socketxtreme_poll(). This function decrements the buff reference count. When buff's reference count reaches zero, it is deallocated.

### 10.7.7 Increment VMA Buffer Reference Counter

Syntax:

```c
int (*socketxtreme_ref_vma_buff)(struct vma_buff_t *buff);
```

Where:
- buff - buffer to be managed

Return values: Returns buffer's reference count after the change. A negative value is returned in case of failure.

Description: Increment the reference counter of a buffer received by socketxtreme_poll(). This function increments the reference count of the buffer. This function should be used in order to hold the buffer even after a call to socketxtreme_free_vma_packets(). When the buffer is no longer required it should be freed via socketxtreme_free_vma_buff().
10.7.8 Usage Example

Sockperf benchmark supports socketxtreme mode. Its source code can be used as a reference of socketxtreme API usage.

The following sample implements server side logic based on the API described above.

In this example, the application just waits for connection requests and accepts new connections.

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unistd.h>
#include <errno.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <arpa/inet.h>
#include <mellanox/vma_extra.h>

int main(int argc, char** argv)
{
    int rc = 0;
    int fd = -1;
    struct sockaddr_in addr;
    static struct vma_api_t _vma_api = NULL;
    static int _vma_ring_fd = -1;
    char *strdev = (argc > 1 ? argv[1] : NULL);
    char *straddr = (argc > 2 ? argv[2] : NULL);
    char *strport = (argc > 3 ? argv[3] : NULL);
    if (!strdev || !straddr || !strport) {
        printf("Wrong options\n");
        exit(1);
    }
    printf("Dev: %s\nAddress: %s\nPort:%s\n", strdev, straddr, strport);
    /* Get VMA extra API reference */
    _vma_api = vma_get_api();
    if (_vma_api == NULL) {
        printf("VMA Extra API not found\n");
        exit(1);
    }
    fd = socket(AF_INET, SOCK_STREAM, IPPROTO_IP);
    rc = setsockopt(fd, SOL_SOCKET, SO_BINDTODEVICE,
                    (void*)strdev, strlen(strdev));
    if (rc < 0) {
        printf("setsockopt() failed %d : %s\n", errno, strerror(errno));
        exit(1);
    }
    bzero(&addr, sizeof(addr));
    addr.sin_family = AF_INET;
    addr.sin_addr.s_addr = inet_addr(straddr);
    addr.sin_port = htons(atoi(strport));
    rc = bind(fd, (struct sockaddr *)&addr, sizeof(addr));
    if (rc < 0) {
        printf("bind() failed : %s\n", strerror(errno));
        exit(1);
    }
    /* RX ring is available after bind() */
    _vma_api->get_socket_rings_fds(fd, &_vma_ring_fd, 1);
    if (_vma_ring_fd == -1){
        printf("Failed to return the ring fd\n");
        exit(1);
    }
    listen(fd, 5);
    printf("Waiting on: fd=%d\n", fd);
    while (0 == rc) {
        struct vma_completion_t vma_comps;
        rc = _vma_api->socketxtreme_poll(_vma_ring_fd, &vma_comps, 1, 0);
        if (rc > 0) {
            printf("socketxtreme_poll: rc=%d event=0x%lx user_data=%ld\n", rc,
                    vma_comps.events, vma_comps.user_data);
            rc = _vma_api->socket_xtreme_new_connectionaccepted(
                &vma_comps.events & VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED,
                printf("Accepted connection: fd=%d\n", (int)vma_comps.user_data);
            if (vma_comps.user_data & VMA_SOCKETXTREME_NEW_CONNECTION_ACCEPTED) {
                printf("Accepted\n");
                close(fd);
                fprintf(stderr, "socket closed\n");
            }
        }
    }
    return 0;
}
```
10.7.9 Installation

For instructions on how to install SocketXtreme, please refer to section Installing VMA with SocketXtreme.

10.7.10 Limitations

No support for:

- Multi-thread
- ConnectX-3/ConnectX-3 Pro HCAs
- MLNX_OFED version lower than v3.4

User should keep in mind the differences in flow between the standard socket API and that based on the polling completions model.

- SocketXtreme mode is used with non-blocking connect() call only
- Do not use accept() because socketxtreme_poll() provides special event as VMA_socketxtreme_NEW_CONNECTION_ACCEPTED to track connection request
- Mixed receive methods (recv/recvfrom/recmsg/epoll_wait with socketXtreme) can cause the user to receive out-of-order packets. UDP is an unreliable protocol, hence working with mixed receive methods are allowed yet not recommended. Whereas TCP is a reliable protocol, hence mixed receive methods are not allowed. socketxtreme_poll() is able to notify about any received data using the event VMA_socketxtreme_PACKET.
11 Monitoring, Debugging, and Troubleshooting

11.1 Monitoring - the vma_stats Utility

Networking applications open various types of sockets.

The VMA library holds the following counters:

- Per socket state and performance counters
- Internal performance counters which accumulate information for select(), poll() and epoll_wait() usage by the whole application. An additional performance counter logs the CPU usage of VMA during select(), poll(), or epoll_wait() calls. VMA calculates this counter only if VMA_CPU_USAGE_STATS parameter is enabled, otherwise this counter is not in use and displays the default value as zero.
- VMA internal CQ performance counters
- VMA internal RING performance counters
- VMA internal Buffer Pool performance counters

Use the included vma_stats utility to view the per-socket information and performance counters during runtime.

Note: For TCP connections, vma_stats shows only offloaded traffic, and not "os traffic."

Usage:

```
#vma_stats [-p pid] [-k directory] [-v view] [-d details] [-i interval]
```

The following table lists the basic and additional vma_stats utility options.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>-p, --pid</td>
<td>&lt;pid&gt;</td>
<td>Shows VMA statistics for a process with pid: &lt;pid&gt;.</td>
</tr>
<tr>
<td>-k, --directory</td>
<td>&lt;directory&gt;</td>
<td>Sets shared memory directory path to &lt;directory&gt;</td>
</tr>
<tr>
<td>-n, --name</td>
<td>&lt;application&gt;</td>
<td>Shows VMA statistics for application: &lt;application&gt;</td>
</tr>
<tr>
<td>-f, --find_pid</td>
<td></td>
<td>Finds PID and shows statistics for the VMA instance running (default).</td>
</tr>
<tr>
<td>-F, --forbid_clean</td>
<td></td>
<td>When you set this flag to inactive, shared objects (files) are not removed.</td>
</tr>
<tr>
<td>-i, --interval</td>
<td>&lt;n&gt;</td>
<td>Prints a report every &lt;n&gt; seconds. Default: 1 sec</td>
</tr>
<tr>
<td>-c, --cycles</td>
<td>&lt;n&gt;</td>
<td>Do &lt;n&gt; report print cycles and exit, use 0 value for infinite. Default: 0</td>
</tr>
<tr>
<td>Parameter Name</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>-v, --view</td>
<td>Shows the runtime basic performance counters (default). 2. Shows extra performance counters. 3. Shows additional application runtime configuration information. 4. Shows multicast group membership information. Shows netstat like view of all sockets.</td>
<td></td>
</tr>
<tr>
<td>-d, --details</td>
<td>Show totals (default). Show deltas.</td>
<td></td>
</tr>
<tr>
<td>-S, --fd_dump</td>
<td>Dumps statistics for fd number &lt;fd&gt; using log level &lt;level&gt;. Use 0 value for all open fds.</td>
<td></td>
</tr>
<tr>
<td>-z, --zero</td>
<td>Zero counters.</td>
<td></td>
</tr>
<tr>
<td>-l, --log_level</td>
<td>Sets the VMA log level to &lt;level&gt; (1 &lt;= level &lt;= 7).</td>
<td></td>
</tr>
<tr>
<td>-D, --details_level</td>
<td>Sets the VMA log detail level to &lt;level&gt; (0 &lt;= level &lt;= 3).</td>
<td></td>
</tr>
<tr>
<td>-s, --sockets</td>
<td>Logs only sockets that match &lt;list&gt; or &lt;range&gt; format: 4-16 or 1,9 (or combination).</td>
<td></td>
</tr>
<tr>
<td>-V, --version</td>
<td>Prints the version number.</td>
<td></td>
</tr>
<tr>
<td>-h, --help</td>
<td>Prints a help message.</td>
<td></td>
</tr>
</tbody>
</table>

### 11.1.1 Examples

The following sections contain examples of the vma_stats utility.

#### 11.1.1.1 Example 1

#### 11.1.1.1.1 Description

The following example demonstrates basic use of the vma_stats utility.

#### 11.1.1.1.2 Command Line

```bash
vma_stats -p <pid>
```

⚠️ If there is only a single process running over VMA, it is not necessary to use the -p option, since vma_stats will automatically recognize the process.

#### 11.1.1.1.3 Output

If no process with a suitable pid is running over the VMA, the output is:
vmastat: Failed to identify process...

If an appropriate process was found, the output is:

```
<table>
<thead>
<tr>
<th>fd</th>
<th>total offloaded</th>
<th>total os</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>140479898</td>
<td>274374</td>
</tr>
</tbody>
</table>
```

**11.1.1.1.4 Output Analysis**

- A single socket with user fd=14 was created
- Received 140479898 packets, 274374 Kilobytes via the socket
- Transmitted 140479898 packets, 274374 Kilobytes via the socket
- All the traffic was offloaded. No packets were transmitted or received via the OS.
- There were no missed Rx polls (see VMA_RX_POLL). This implies that the receiving thread did not enter a blocked state, and therefore there was no context switch to hurt latency.
- There are no transmission or reception errors on this socket

**11.1.1.2 Example 2**

**11.1.1.2.1 Description**

vma_stats presents not only cumulative statistics, but also enables you to view deltas of VMA counter updates. This example demonstrates the use of the “deltas” mode.

**11.1.1.2.2 Command Line**

```
#vma_stats -p <pid> -d
```

**11.1.1.2.3 Output**

```
<table>
<thead>
<tr>
<th>fd</th>
<th>total offloaded</th>
<th>total os</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>15186</td>
<td>0</td>
</tr>
<tr>
<td>19</td>
<td>15186</td>
<td>0</td>
</tr>
<tr>
<td>23</td>
<td>15185</td>
<td>0</td>
</tr>
</tbody>
</table>
```

**11.1.1.2.4 Output Analysis**

- Three sockets were created (fds: 15, 19, and 23)
- Received 15186 packets, 29 Kilobytes during the last second via fds: 15 and 19
- Transmitted 15186 packets, 29 Kbytes during the last second via fds: 15 and 19
- Not all the traffic was offloaded, as fd 23: 15185 packets, 22 KBytes were transmitted and received via the OS. This means that fd 23 was used for unicast traffic.
- No transmission or reception errors were detected on any socket
- The application used select for I/O multiplexing
• 45557 packets were placed in socket ready queues (over the course of the last second): 30372 of them offloaded (15186 via fd 15 and 15186 via fd 19), and 15185 were received via the OS (through fd 23)
• There were no missed Select polls (see VMA_SELECT_POLL). This implies that the receiving thread did not enter a blocked state. Thus, there was no context switch to hurt latency.
• The CPU usage in the select call is 70%

You can use this information to calculate the division of CPU usage between VMA and the application. For example when the CPU usage is 100%, 70% is used by VMA for polling the hardware, and the remaining 30% is used for processing the data by the application.

11.1.1.3 Example 3

11.1.1.3.1 Description

This example presents the most detailed vma_stats output.

11.1.1.3.2 Command Line

```
#vma_stats -p <pid> -v 3 -d 2
```

11.1.1.3.3 Output

```
=================================================================
FID=[14]
- Blocked, MC Loop Enabled
- Bound IF = [0.0.0.0:11111]

```

11.1.1.3.4 Output Analysis

• A single socket with user fd=14 was created
• The socket is a member of multicast group: 224.7.7.7
• Received 786133 packets, 1128530 Kilobytes via the socket during the last second
• No transmitted data
• All the traffic was offloaded. No packets were transmitted or received via the OS
• There were almost no missed Rx polls (see VMA_RX_POLL)
• There were no transmission or reception errors on this socket
• The sockets receive buffer size is 16777216 Bytes
• There were no dropped packets caused by the socket receive buffer limit (see VMA_RX_BYTES_MIN)
• Currently, one packet of 1470 Bytes is located in the socket receive queue
• The maximum number of packets ever located, simultaneously, in the sockets receive queue is 16
• No packets were dropped by the CQ
• No packets in the CQ ready queue (packets which were drained from the CQ and are waiting to be processed by the upper layers)
• The maximum number of packets drained from the CQ during a single drain cycle is 511 (see VMA_CQ_DRAIN_WCE_MAX)
• The RING_ETH received 786133 packets during this period
• The RING_ETH received 1192953 kilo bytes during this period. This includes headers bytes.
• 786137 interrupts were requested by the ring during this period
• 78613 interrupts were intercepted by the ring during this period
• The moderation engine was set to trigger an interrupt for every 10 packets and with maximum time of 181 usecs
• There were no retransmissions
• The current available buffers in the RX pool is 168000
• The current available buffers in the TX pool is 199488
• There were no buffer requests that failed (no buffer errors)

11.1.1.4 Example 4

11.1.1.4.1 Description

This example demonstrates how you can get multicast group membership information via vma_stats.

11.1.1.4.2 Command Line

```
vma_stats -p <pid> -v 4
```

11.1.1.4.3 Output

```
VMA Group Membership Information
Group                fd number
-------------------------------
[224.4.1.3]               15
[224.4.1.2]               19
```

11.1.1.5 Example 5

11.1.1.5.1 Description

This is an example of the “netstat like” view of vma_stats (-v 5).
11.1.1.5.2 Output

<table>
<thead>
<tr>
<th>Proto</th>
<th>Offloaded</th>
<th>Local Address</th>
<th>Foreign Address</th>
<th>State</th>
<th>Inode</th>
<th>PID</th>
</tr>
</thead>
<tbody>
<tr>
<td>udp</td>
<td>Yes</td>
<td>0.0.0.0:44522</td>
<td>0.0.0.0:*</td>
<td>LISTEN</td>
<td>733679757</td>
<td>1576</td>
</tr>
<tr>
<td>tcp</td>
<td>Yes</td>
<td>0.0.0.0:11111</td>
<td>0.0.0.0:*</td>
<td>LISTEN</td>
<td>733679919</td>
<td>1618</td>
</tr>
</tbody>
</table>

11.1.1.5.3 Output Analysis
- Two processes are running VMA
- PID 1576 has one UDP socket bounded to all interfaces on port 44522
- PID 1618 has one TCP listener socket bounded to all interfaces on port 11111

11.1.1.6 Example 6

11.1.1.6.1 Description
This is an example of a log of socket performance counters along with an explanation of the results (using VMA_STATS_FILE parameter).

11.1.1.6.2 Output

VMA: [fd=10] Tx Offload: 455 / 233020 / 0 [kilobytes/packets/errors]
VMA: [fd=10] Tx OS info: 0 / 0 / 0 [kilobytes/packets/errors]
VMA: [fd=10] Rx Offload: 455 / 233020 / 0 [kilobytes/packets/errors]
VMA: [fd=10] Rx OS info: 0 / 0 / 0 [kilobytes/packets/errors]
VMA: [fd=10] Rx byte: max 200 / dropped 0 (0.0%) / limit 2000000
VMA: [fd=10] Rx pkt : max 1 / dropped 0 (0.0%)  
VMA: [fd=10] Rx poll: 0 / 233020 (100.0%) [miss/hit]

11.1.1.6.3 Output Analysis
- No transmission or reception errors occurred on this socket (user fd=10).
- All the traffic was offloaded. No packets were transmitted or received via the OS.
- There were practically no missed Rx polls (see VMA_RX_POLL and VMA_SELECT_POLL). This implies that the receiving thread did not enter a blocked state. Thus, there was no context switch to hurt latency.
- There were no dropped packets caused by the socket receive buffer limit (see VMA_RX_BYTES_MIN). A single socket with user fd=14 was created.

11.1.1.7 Example 7

11.1.1.7.1 Description
This is an example of vma_stats fd dump utility of established TCP socket using log level = info.

11.1.1.7.2 Command Line

```bash
#vma_stats --fd_dump 17 info
```
11.1.1.7.3 Output

VMA INFO: ============ --- ============

11.1.1.7.4 Output Analysis

- Fd 17 is a descriptor of established TCP socket (22.0.0.4:58795 -> 22.0.0.3:6666)
- Fd 17 is offloaded by VMA
- The current usage of the receive buffer is 0 bytes, while the max possible is 87380
- The connection (PCB) flags are TF_WND_SCALE and TF_NODELAY (PCB0x140)
- Window scaling is enabled, receive and send scales equal 7
- Congestion windows equal 1662014
- Unsented queue is empty
- There is a single packet of 14 bytes in the unacked queue (seqno 12678066)
- The last acknowledgment sequence number is 12678066

Additional information about the values can be found in the VMA's wiki page.

11.2 Debugging

11.2.1 VMA Logs

Use the VMA logs in order to trace VMA operations. VMA logs can be controlled by the VMA_TRACELEVEL variable. This variable's default value is 3, meaning that the only logs obtained are those with severity of PANIC, ERROR, and WARNING.

You can increase the VMA_TRACELEVEL variable value up to 6 (as described in VMA Configuration Parameters) to see more information about each thread's operation. Use the VMA_LOG_DETAILS=3 to
add a time stamp to each log line. This can help to check the time difference between different events written to the log.

Use the `VMA_LOG_FILE=/tmp/my_file.log` to save the daily events. It is recommended to check these logs for any VMA warnings and errors. Refer to the Troubleshooting section to help resolve the different issues in the log.

VMA will replace a single ‘%d’ appearing in the log file name with the pid of the process loaded with VMA. This can help in running multiple instances of VMA each with its own log file name.

When `VMA_LOG_COLORS` is enabled, VMA uses a color scheme when logging: Red for errors and warnings, and dim for low level debugs.

Use the `VMA_HANDLE_SIGSEGV` to print a backtrace if a segmentation fault occurs.

11.2.2 Ethernet Counters

Look at the Ethernet counters (by using the `ifconfig` command) to understand whether the traffic is passing through the kernel or through the VMA (Rx and Tx).

11.2.3 tcpdump

For `tcpdump` to capture offloaded traffic (on ConnectX-4 and above), please follow instructions in section Offloaded Traffic Sniffer in the MLNX_OFED User Manual.

11.2.4 NIC Counters

Look at the NIC counters to monitor HW interface level packets received and sent, drops, errors, and other useful information.

```
ls /sys/class/net/eth2/statistics/
```

11.3 Peer Notification Service

Peer notification service handles TCP half-open connections where one side discovers the connection was lost but the other side still see it as active.

The peer-notification daemon is started at system initialization or manually under super user permissions.

The daemon collects information about TCP connections from all the running VMA processes. Upon VMA process termination (identified as causing TCP half open connection) the daemon notifies the peers (by sending Reset packets) in order to let them delete the TCP connections on their side.

11.4 Troubleshooting

This section lists problems that can occur when using VMA, and describes solutions for these problems.

1. High Log Level
This warning message indicates that you are using VMA with a high log level. The VMA_TRACELEVEL variable value is set to 4 or more, which is good for troubleshooting but not for live runs or performance measurements.

**Solution:** Set VMA_TRACELEVEL to its default value 3.

2. On running an application with VMA, the following error is reported:

```
ERROR: ld.so: object 'libvma.so' from LD_PRELOAD cannot be preloaded: ignored.
```

**Solution:** Check that libvma is properly installed, and that libvma.so is located in /usr/lib (or in /usr/lib64, for 64-bit machines).

3. On attempting to install vma rpm, the following error is reported:

```
#rpm -ivh libvma-w.x.y-z.rpm
error: can't create transaction lock
```

**Solution:** Install the rpm with privileged user (root).

4. The following warning is reported:

```
VMA: WARNING: *****************************************************
VMA: WARNING: Your current max locked memory is: 33554432. Please change it to unlimited.
VMA: WARNING: Set this user's default to `ulimit -l unlimited`.
VMA: WARNING: Read more about this issue in the VMA's User Manual.
VMA: WARNING: *****************************************************
```

**Solution:** When working with root, increase the maximum locked memory to 'unlimited' by using the following command:

```
#ulimit -l unlimited
```

When working as a non-privileged user, ask your administrator to increase the maximum locked memory to unlimited.

5. Lack of huge page resources in the system. The following warning is reported:

```
VMA WARNING: **************************************************************
VMA WARNING: * NO IMMEDIATE ACTION NEEDED! *
VMA WARNING: * Not enough hugepage resources for VMA memory allocation. *
VMA WARNING: * VMA will continue working with regular memory allocation. *
VMA INFO: * Optional: *
VMA INFO: * 1. Switch to a different memory allocation type *
VMA INFO: * (VMA_MEM_ALLOC_TYPE!= 2) *
VMA INFO: * 2. Restart process after increasing the number of *
VMA INFO: * hugepage resources in the system: *
VMA INFO: * "echo 1000000000 > /proc/sys/vm/nr_hugepages" *
VMA INFO: * "echo 800 > /proc/sys/vm/nr_hugepages" *
VMA WARNING: * Please refer to the memory allocation section in the VMA's *
VMA WARNING: * User Manual for more information *
VMA WARNING: **************************************************************
```

This warning message means that you are using VMA with huge page memory allocation enabled (VMA_MEM_ALLOC_TYPE=2), but not enough huge page resources are available in the system. VMA will use contiguous pages instead.

Note that VMA_MEM_ALLOC_TYPE= 1 is not supported while working with Microsoft hypervisor. In this case - please use VMA_MEM_ALLOC_TYPE= 0 (malloc).

If you want VMA to take full advantage of the performance benefits of huge pages, restart the application after adding more huge page resources to your system similar to the details in the
If you are running multiple instances of your application loaded with VMA, you will probably need to increase the values used in the above example.

- Check that your host machine has enough free memory after allocating the huge page resources for VMA. Low system memory resources may cause your system to hang.

- Use `ipcs -m` and `ipcrm -m shmid` to check and clean unused shared memory segments.

Use the following script to release VMA unused huge page resources:

```bash
for shmid in `ipcs -m | grep 0x00000000 | awk '{print $2}'`; do
echo 'Clearing' $shmid; ipcrm -m $shmid;
done;
```

Wrong ARP resolution when multiple ports are on the same network. When two (or more) ports are configured on the same network (e.g. 192.168.1.1/24 and 192.168.1.2/24) VMA will only detect the MAC address of one of the interfaces. This will result in incorrect ARP resolution.

This is due to the way Linux handles ARP responses in this configuration. By default, Linux returns the same MAC address for both IPs. This behavior is called “ARP Flux”.

To fix this, it is required to change some of the interface’s settings:

```bash
$ sysctl -w net.ipv4.conf.[DEVICE].arp_announce=1
$ sysctl -w net.ipv4.conf.[DEVICE].arp_ignore=2
$ sysctl -w net.ipv4.conf.[DEVICE].rp_filter=0
```

To verify the issue is resolved, clear the ARP tables on a different server that is on the same network and use the `arping` utility to verify that each IP reports its own MAC address correctly:

```bash
$ ip -s neigh flush all  # clear the arp table on the remote server
$ arping -b -I ens3f1 192.168.1.1
Unicast reply from 192.168.1.1 [24:8A:07:9A:16:0A] 0.548ms
$ arping -b -I ens3f1 192.168.1.2
Unicast reply from 192.168.1.2 [24:8A:07:9A:16:1A] 0.548ms
```

VMA process cannot establish connection with daemon (vmad) in Microsoft hypervisor environment.

When working with Microsoft Hypervisor, VMA daemon must be enabled in order to submit Traffic Control (TC) rules which will offload the traffic to the TAP device in case of plug-out events.

The following warning is reported during VMA startup:
The following warning is reported during any connection establishment/termination:

```plaintext
VMA WARNING: ring_tap[0x1efc910]:135:attach_flow() Add TC rule failed with error=-19
```

To fix this, run “vmad” as root.

8. **VMA cannot offload traffic when RoCE LAG is enabled.**

RoCE LAG is a feature meant for mimicking Ethernet bonding for IB devices and is available for dual port cards only. When in RoCE LAG mode, instead of having an IB device per physical port (for example mlx5_0 and mlx5_1), only one IB device is present for both ports.

The following warning appears upon VMA startup:

```plaintext
VMA WARNING: *****************************************************************
VMA WARNING: * Interface bond0 will not be offloaded.
VMA WARNING: * VMA cannot offload the device while RoCE LAG is enabled.
VMA WARNING: * Please refer to VMA Release Notes for more info
VMA WARNING: *****************************************************************
VMA WARNING: *****************************************************************
VMA WARNING: * Bond bond0 will not be offloaded due to problem with its slaves.
VMA WARNING: * Check warning messages for more information.
VMA WARNING: *****************************************************************
```

RoCE LAG should be disabled in order for VMA to be able to offload traffic.

ConnectX-4 and above HCAs with MLNX_OFED print the following warning with instructions on how to disable RoCE LAG:

```plaintext
VMA WARNING: *****************************************************************
VMA WARNING: * Interface bond1 will not be offloaded.
VMA WARNING: * VMA cannot offload the device while RoCE LAG is enabled.
VMA WARNING: * In order to disable RoCE LAG please use:
VMA WARNING: * echo 0 > /sys/class/net/ens4f1/device/roce_lag_enable
VMA WARNING: *****************************************************************
VMA WARNING: *****************************************************************
VMA WARNING: * Bond bond1 will not be offloaded due to problem with its slaves.
VMA WARNING: * Check warning messages for more information.
VMA WARNING: *****************************************************************
```

9. **Device memory programming is not supported on VMs that lack Blue Flame support.**

VMA will explicitly disable Device Memory capability if it detects Blue Flame support is missing on the node on which user application was launched using VMA. The following warning message will appear:

```plaintext
VMA: WARNING: Device Memory functionality is not used on devices w/o Blue Flame support.
```
12 Appendixes

The document contains the following appendixes:

- Appendix: Sockperf - UDP/TCP Latency and Throughput Benchmarking Tool
- Appendix: Multicast Routing

12.1 Appendix: Sockperf - UDP/TCP Latency and Throughput Benchmarking Tool

This appendix presents *sockperf*, VMA’s sample application for testing latency and throughput over socket API.

*Sockperf* can be used natively, or with VMA acceleration.

12.1.1 Overview

*Sockperf* is an open source utility. For more general information, see https://github.com/Mellanox/sockperf.

Sockperf’s advantage over other network benchmarking utilities is its focus on testing the performance of high-performance systems (as well as testing the performance of regular networking systems). In addition, sockperf covers most of the socket API call and options.

Specifically, in addition to the standard throughput tests, sockperf:

- Measures latency of each discrete packet at sub-nanosecond resolution (using TSC register that counts CPU ticks with very low overhead).
- Measures latency for ping-pong mode and for latency under load mode. This means that you can measure latency of single packets even under a load of millions of PPS (without waiting for reply of packet before sending a subsequent packet on time).
- Enables spike analysis by providing in each run a histogram with various percentiles of the packets’ latencies (for example: median, min, max, 99% percentile, and more) in addition to average and standard deviation.
- Can provide full logs containing all a packet’s tx/rx times, without affecting the benchmark itself. The logs can be further analyzed with external tools, such as MS-Excel or matplotlib.
- Supports many optional settings for good coverage of socket API, while still keeping a very low overhead in the fast path to allow cleanest results.

Sockperf operates by sending packets from the client (also known as the *publisher*) to the server (also known as the *consumer*), which then sends all or some of the packets back to the client. This measured roundtrip time is the route trip time (RTT) between the two machines on a specific network path with packets of varying sizes.

- The latency for a given one-way path between the two machines is the RTT divided by two.
- The average RTT is calculated by summing the route trip times for all the packets that perform the round trip and then dividing the total by the number of packets.

Sockperf can test the improvement of UDP/TCP traffic latency when running applications with and without VMA.
Sockperf can work as a server (consumer) or execute under-load, ping-pong, playback and throughput tests as a client (publisher).

In addition, sockperf provides more detailed statistical information and analysis, as described in the following section.

Sockperf is installed on the VMA server at `/usr/bin/sockperf`. For examples of running sockperf, see:
- Latency with Ping-pong Test
- Bandwidth and Packet Rate With Throughput Test

⚠️ If you want to use multicast, you must first configure the routing table to map multicast addresses to the Ethernet interface, on both client and server. (See Configuring the Routing Table for Multicast Tests).

12.1.1.1 Advanced Statistics and Analysis

In each run, sockperf presents additional advanced statistics and analysis information:
- In addition to the average latency and standard deviation, sockperf presents a histogram with various percentiles, including:
  - 50 percentile - the latency value for which 50 percent of the observations are smaller than it. The 50 percentile is also known as the median, and is different from the statistical average.
  - 99 percentile - the latency value for which 99 percent of the observations are smaller than it (and 1 percent are higher)

These percentiles, and the other percentiles that the histogram provides, are very useful for analyzing spikes in the network traffic.
- Sockperf can provide a full log of all packets’ tx and rx times by dumping all the data that it uses for calculating percentiles and building the histogram to a comma separated file. This file can be further analyzed using external tools such as Microsoft Excel or matplotlib.

All these additional calculations and reports are executed after the fast path is completed. This means that using these options has no effect on the benchmarking of the test itself. During runtime of the fast path, sockperf records txTime and rxTime of packets using the TSC CPU register, which has a negligible effect on the benchmark itself, as opposed to using the computer’s clock, which can affect benchmarking results.

12.1.2 Configuring the Routing Table for Multicast Tests

If you want to use multicast, you must first configure the routing table to map multicast addresses to the Ethernet interface, on both client and server.

Example

```bash
# route add -net 224.0.0.0 netmask 240.0.0.0 dev eth0
```

where `eth0` is the Ethernet interface.

You can also set the interface on runtime in sockperf:
• Use "--mc-rx-if -<ip>" to set the address of the interface on which to receive multicast packets (can be different from the route table)
• Use "--mc-tx-if -<ip>" to set the address of the interface on which to transmit multicast packets (can be different from the route table)

12.1.3 Latency with Ping-pong Test

To measure latency statistics, after the test completes, sockperf calculates the route trip times (divided by two) between the client and the server for all messages, then it provides the average statistics and histogram.

12.1.3.1 UDP Ping-pong

To run UDP ping-pong:

1. Run the server by using:
   
   ```bash
   # sockperf sr -i <server-ip>
   ```

2. Run the client by using:
   
   ```bash
   # sockperf pp -i <server-ip> -m 64
   ```
   
   Where `-m/--msg-size` is the message size in bytes (minimum default 14).

   *For more sockperf Ping-pong options run:
   
   ```bash
   # sockperf pp -h
   ```

12.1.3.2 TCP Ping-pong

To run TCP ping-pong:

1. Run the server by using:
   
   ```bash
   # sockperf ar -i <server-ip> --tcp
   ```

2. Run the client by using:
   
   ```bash
   # sockperf pp -i <server-ip> --tcp -m 64
   ```

12.1.3.3 TCP Ping-pong using VMA

To run TCP ping-pong using VMA:

1. Run the server by using:
   
   ```bash
   # VMA_SPEC=latency LD_PRELOAD=libvma.so sockperf ar -i <server-ip> --tcp
   ```
2. Run the client by using:

```
# VMA_SPEC=latency LD_PRELOAD=libvma.so sockperf pp -i <server-ip> --tcp -m 64
```

Where `VMA_SPEC=latency` is a predefined specification profile for latency.

12.1.4 Bandwidth and Packet Rate with Throughput Test

To determine the maximum bandwidth and highest message rate for a single-process, single-threaded network application, sockperf attempts to send the maximum amount of data in a specific period of time.

12.1.4.1 UDP MC Throughput

To run UDP MC throughput:

1. On both the client and the server, configure the routing table to map the multicast addresses to the interface by using:

```
# route add -net 224.0.0.0 netmask 240.0.0.0 dev <interface>
```

2. Run the server by using:

```
# sockperf sr -i <server-100g-ip>
```

3. Run the client by using:

```
# sockperf tp -i <server-100g-ip> -m 1472
```

Where `-m/--msg-size` is the message size in bytes (minimum default 14).

4. The following output is obtained:

```
sockperf: Total of 936977 messages sent in 1.100 sec
sockperf: Summary: Message Rate is 851796 [msg/sec]
sockperf: Summary: BandWidth is 1195.759 MBps (9566.068 Mbps)
```

⚠️ For more sockperf throughput options run:

```
# sockperf tp -h
```

12.1.4.2 UDP MC Throughput using VMA

To run UDP MC throughput:

1. After configuring the routing table as described in Configuring the Routing Table for Multicast Tests, run the server by using:

```
# LD_PRELOAD=libvma.so sockperf sr -i <server-ip>
```

2. Run the client by using:
# LD_PRELOAD=libvma.so sockperf tp -i <server-ip> -m 1472

3. The following output is obtained:

```
sockperf: Total of 4651163 messages sent in 1.100 sec
sockperf: Summary: Message Rate is 4228326 [msg/sec]
sockperf: Summary: BandWidth is 5935.760 MBps (47486.083 Mbps)
```

### 12.1.4.3 UDP MC Throughput Summary

<table>
<thead>
<tr>
<th>Test</th>
<th>100 Gb Ethernet</th>
<th>100 Gb Ethernet + VMA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message Rate</td>
<td>851796 [msg/sec]</td>
<td>4228326 [msg/sec]</td>
</tr>
<tr>
<td>Bandwidth</td>
<td>1195.759 MBps (9566.068 Mbps)</td>
<td>5935.760 MBps (47486.083 Mbps)</td>
</tr>
<tr>
<td>VMA Improvement</td>
<td>4740.001 MBps (396.4%)</td>
<td></td>
</tr>
</tbody>
</table>

### 12.1.5 sockperf Subcommands

You can use additional sockperf subcommands

Usage: sockperf <subcommand> [options] [args]

- To display help for a specific subcommand, use:
  ```
  sockperf <subcommand> --help
  ```

- To display the program version number, use:
  ```
  sockperf --version
  ```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
<th>For help, use</th>
</tr>
</thead>
<tbody>
<tr>
<td>help (h,?)</td>
<td>Display a list of supported commands.</td>
<td># sockperf ul -h</td>
</tr>
<tr>
<td>under-load (ul)</td>
<td>Run sockperf client for latency under load test.</td>
<td># sockperf pp -h</td>
</tr>
<tr>
<td>ping-pong (pp)</td>
<td>Run sockperf client for latency test in ping pong mode.</td>
<td># sockperf pp -h</td>
</tr>
<tr>
<td>playback (pb)</td>
<td>Run sockperf client for latency test using playback of predefined traffic, based on timeline and message size.</td>
<td># sockperf pb -h</td>
</tr>
<tr>
<td>throughput (tp)</td>
<td>Run sockperf client for one way throughput test.</td>
<td># sockperf tp -h</td>
</tr>
<tr>
<td>server (sr)</td>
<td>Run sockperf as a server.</td>
<td># sockperf sr -h</td>
</tr>
</tbody>
</table>

For additional information, see [https://github.com/Mellanox/sockperf](https://github.com/Mellanox/sockperf).

### 12.1.5.1 Additional Options

The following tables describe additional sockperf options, and their possible values.
### 12.1.5.1.1 Client Options

<table>
<thead>
<tr>
<th>Short Command</th>
<th>Full Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h, -?</td>
<td>--help, --usage</td>
<td>Show the help message and exit.</td>
</tr>
<tr>
<td>N/A</td>
<td>--tcp</td>
<td>Use TCP protocol (default UDP).</td>
</tr>
<tr>
<td>-i</td>
<td>--ip</td>
<td>Listen on/send to IP &lt;ip&gt;.</td>
</tr>
<tr>
<td>-p</td>
<td>--port</td>
<td>Listen on/connect to port &lt;port&gt; (default 11111).</td>
</tr>
<tr>
<td>-f</td>
<td>--file</td>
<td>Read multiple ip+port combinations from file &lt;file&gt; (will use IO muxer '-F').</td>
</tr>
<tr>
<td>-F</td>
<td>--iomux-type</td>
<td>Type of multiple file descriptors handle [s</td>
</tr>
<tr>
<td>N/A</td>
<td>--timeout</td>
<td>Set select/poll/epoll timeout to &lt;msec&gt; or -1 for infinite (default is 10 msec).</td>
</tr>
<tr>
<td>-a</td>
<td>--activity</td>
<td>Measure activity by printing a <code>.</code> for the last &lt;N&gt; messages processed.</td>
</tr>
<tr>
<td>-A</td>
<td>--Activity</td>
<td>Measure activity by printing the duration for last &lt;N&gt; messages processed.</td>
</tr>
<tr>
<td>N/A</td>
<td>--tcp-avoid-nodelay</td>
<td>Stop/Start delivering TCP Messages Immediately (Enable/Disable Nagel). The default is Nagel Disabled except for in Throughput where the default is Nagel enabled.</td>
</tr>
<tr>
<td>N/A</td>
<td>--tcp-skip-blocking-send</td>
<td>Enables non-blocking send operation (default OFF).</td>
</tr>
<tr>
<td>N/A</td>
<td>--tos</td>
<td>Allows setting tos.</td>
</tr>
<tr>
<td>N/A</td>
<td>--mc-rx-if</td>
<td>IP address of interface on which to receive multicast packets (can be different from the route table).</td>
</tr>
<tr>
<td>N/A</td>
<td>--mc-tx-if</td>
<td>IP address of interface on which to transmit multicast packets (can be different from the route table).</td>
</tr>
<tr>
<td>N/A</td>
<td>--mc-loopback-enable</td>
<td>Enable MC loopback (default disabled).</td>
</tr>
<tr>
<td>N/A</td>
<td>--mc-ttl</td>
<td>Limit the lifetime of the message (default 2).</td>
</tr>
<tr>
<td>N/A</td>
<td>--mc-source-filter</td>
<td>Set the address &lt;ip, hostname&gt; of the multicast messages source which is allowed to receive from.</td>
</tr>
<tr>
<td>N/A</td>
<td>--uc-reuseaddr</td>
<td>Enables unicast reuse address (default disabled).</td>
</tr>
<tr>
<td>N/A</td>
<td>--lls</td>
<td>Turn on LLS via socket option (value = usec to poll).</td>
</tr>
<tr>
<td>N/A</td>
<td>--buffer-size</td>
<td>Set total socket receive/send buffer &lt;size&gt; in bytes (system defined by default).</td>
</tr>
<tr>
<td>N/A</td>
<td>--nonblocked</td>
<td>Open non-blocked sockets.</td>
</tr>
<tr>
<td>N/A</td>
<td>--recv_looping_num</td>
<td>Set sockperf to loop over recvfrom() until EAGAIN or &lt;N&gt; good received packets, -1 for infinite, must be used with --nonblocked (default 1).</td>
</tr>
<tr>
<td>Short Command</td>
<td>Full Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>N/A</td>
<td>--dontwarmup</td>
<td>Do not send warm up packets on start.</td>
</tr>
<tr>
<td>N/A</td>
<td>--pre-warmup-wait</td>
<td>Time to wait before sending warm up packets (seconds).</td>
</tr>
<tr>
<td>N/A</td>
<td>--vmazcopyread</td>
<td>If possible use VMA's zero copy reads API (see the VMA readme).</td>
</tr>
<tr>
<td>N/A</td>
<td>--daemonize</td>
<td>Run as daemon.</td>
</tr>
<tr>
<td>N/A</td>
<td>--no-rdtsc</td>
<td>Do not use the register when measuring time; instead use the monotonic clock.</td>
</tr>
<tr>
<td>N/A</td>
<td>--load-vma</td>
<td>Load VMA dynamically even when LD_PRELOAD was not used.</td>
</tr>
<tr>
<td>N/A</td>
<td>--rate-limit</td>
<td>Use rate limit (packet-pacing). When used with VMA, it must be run with VMA_RING_ALLOCATION_LOGIC_TX mode.</td>
</tr>
<tr>
<td>N/A</td>
<td>--set-sock-accl</td>
<td>Set socket acceleration before running VMA (available for some NVIDIA® systems).</td>
</tr>
<tr>
<td>-d</td>
<td>--debug</td>
<td>Print extra debug information.</td>
</tr>
</tbody>
</table>

12.1.5.1.2 Server Options

<table>
<thead>
<tr>
<th>Short Command</th>
<th>Full Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>N/A</td>
<td>--threads-num</td>
<td>Run &lt;N&gt; threads on server side (requires <code>-f</code> option).</td>
</tr>
<tr>
<td>N/A</td>
<td>--cpu-affinity</td>
<td>Set threads affinity to the given core IDs in the list format (see: cat /proc/cpuinfo).</td>
</tr>
<tr>
<td>N/A</td>
<td>--vmarxfiltercb</td>
<td>If possible use VMA's receive path packet filter callback API (See the VMA readme).</td>
</tr>
<tr>
<td>N/A</td>
<td>--force-unicast-reply</td>
<td>Force server to reply via unicast.</td>
</tr>
<tr>
<td>N/A</td>
<td>--dont-reply</td>
<td>Set server to not reply to the client messages.</td>
</tr>
<tr>
<td>-m</td>
<td>--msg-size</td>
<td>Set maximum message size that the server can receive &lt;size&gt; bytes (default 65507).</td>
</tr>
<tr>
<td>-g</td>
<td>--gap-detection</td>
<td>Enable gap-detection.</td>
</tr>
</tbody>
</table>

12.1.5.2 Sending Bursts

Use the "-b (--burst=<size>)" option to control the number of messages sent by the client in every burst.

12.1.5.3 SocketXtreme

sockperf v3.2 and above supports VMA socketXtreme polling mode.

In order to support socketXtreme, sockperf should be configured using --enable-vma-api parameter compiled with the compatible vma_extra.h file during compilation.
New iomux type should appear -x / --socketxtreme:

<table>
<thead>
<tr>
<th>Short Command</th>
<th>Full Command</th>
<th>Description</th>
</tr>
</thead>
</table>
| -F            | --iomux-type | Type of multiple file descriptors handle [s|select| p|poll|e|epoll|r|recvfrom|x|socketxtreme] (default epoll).

⚠️ SocketXtreme should be also enabled for VMA. For further information, please refer to **Installing VMA with SocketXtreme**.

In order to use socketXtreme, VMA should also be compiled using --enable-socketxtreme parameter. socketXtreme requires forcing the Client side to bind to a specific IP address. Hence, while running UDP client with socketXtreme, running **--client_ip** is mandatory:

```
--client_ip  -Force the client side to bind to a specific ip address (default = 0).
```

### 12.1.6 Debugging sockperf

Use "-d (--debug)" to print extra debug information without affecting the results of the test. The debug information is printed only before or after the fast path.

### 12.1.7 Troubleshooting sockperf

1. If the following error is received:

```
sockperf error:
sockperf: No messages were received from the server. Is the server down?
```

Perform troubleshooting as follows:

- Make sure that exactly one server is running
- Check the connection between the client and server
- Check the routing table entries for the multicast/unicast group
- Extend test duration (use the "--time" command line switch)
- If you used extreme values for **--mps** and/or **--reply-every** switch, try other values or try the default values

2. If the following error is received, it means that Sockperf is trying to compile against VMA with no socketXtreme support:

```
In file included from src/Client.cpp:33:
src/iohandlers.h: In member function 'int IoSocketxtreme::waitArrival()':
src/iohandlers.h:421:7: error: 'VMA_SOCKETXTREME_PACKET' was not declared in this scope
  if (m_rings_vma_comps_map_itr->second->vma_comp_list[i].events & VMA_SOCKETXTREME_PACKET){
  ^
src/iohandlers.h:422:18: error: 'struct vma_api_t' has no member named 'socketxtreme_free_vma_packets'
g_vma_api->socketxtreme_free_vma_packets(m_rings_vma_comps_map_itr->second->vma_comp_list[i].packet, 1);
```

There are two ways to solve this:

- Configure sockperf with **--disable-vma-api** parameter;
- or
- Use VMA 8.5.1 or above
12.2 Appendix: Multicast Routing

12.2.1 Multicast Interface Definitions

All applications that receive and/or transmit multicast traffic on a multiple-interface host should define the network interfaces through which they would prefer to receive or transmit the various multicast groups.

If a networking application can use existing socket API semantics for multicast packet receive and transmit, the network interface can be defined by mapping the multicast traffic. In this case, the routing table does not have to be updated for multicast group mapping. The socket API setsockopt handles these definitions.

When the application uses setsockopt with IP_ADD_MEMBERSHIP for the receive path multicast join request, it defines the interface through which it wants the VMA to join the multicast group, and listens for incoming multicast packets for the specified multicast group on the specified socket.

IGMPv3 source specific multicast: when the application uses setsockopt with IP_ADD_SOURCE_MEMBERSHIP for the receive path multicast join request, it defines the interface through which it wants the VMA to join the multicast group, and listens for incoming multicast packets for the specified multicast group and from a specified source on the specified socket.

When the application uses setsockopt with IP_MULTICAST_IF on the transmit path, it defines the interface through which the VMA will transmit outgoing multicast packets on that specific socket.

If the user application does not use any of the above setsockopt socket lib API calls, the VMA uses the network routing table mapping to find the appropriate interface to be used for receiving or transmitting multicast packets.

Use the route command to verify that multicast addresses in the routing table are mapped to the interface you are working on. If they are not mapped, you can map them as follows:

```
route add -net 224.0.0.0 netmask 240.0.0.0 dev ib0
```

It is best to perform the mapping before running the user application with VMA, so that multicast packets are routed via the 10 Gb Ethernet interface and not via the default Ethernet interface eth0.

The general rule is that the VMA routing is the same as the OS routing.

### 15.1 Release Notes Change History

<table>
<thead>
<tr>
<th>Release</th>
<th>Description</th>
</tr>
</thead>
</table>
| 9.8.5   | • Updated MLNX_OFED and Firmware versions. See [System Requirements and Interoperability](#)  
         | • Added full support of TCP_KEEPALIVE option  
         | • See [Bug Fixes History](#) section. |
| 9.8.4   | • Removed DPCP dependency from VMA.  
         | • See [Bug Fixes History](#) section. |
| 9.8.3   | • See [Bug Fixes History](#) section. |
| 9.5.2   | • Changed the default visibility of socIPoIB is temporarily unavailable when ket API symbols by hiding internal symbols and enabling export-only functions. This change in the default library configuration helps to:  
         | • Substantially improve the load time of the library  
         | • Produce better code quality by the optimizer  
         | • Reduces chances of symbol collision  
         | • Product source code is migrated to C++11 standard requirements.  
         | • See [Bug Fixes](#) section. |
| 9.4.0   | • Updated [Certified Applications](#).  
         | • Updated [Known Issues](#).  
         | • See [Bug Fixes](#) section. |
| 9.2.2   | • Added RoCE LAG support to VMA over MLNX_OFED RDMA-Core.  
         | • [Bug Fixes](#). |
| 9.1.1   | • Added man pages for libvma.  
         | • Added support for UDP 5 tuple hardware flow steering rules.  
         | • Added support for a new environment variable [VMA_UDP_3T_RULES](#).  
         | • Removed support for ConnectX-3 and ConnectX-3 Pro NICs.  
         | • See [Bug Fixes](#) section. |
| 9.0.2   | • Added the option for VMA daemon to set spoofed SYN retry interval.  
         | • See [Bug Fixes](#) section. |
| 8.9.4   | • See [Bug Fixes](#) section. |
| 8.8.3   | • Added SocketXtreme API support to the same VMA binary as the traditional Socket API.  
         | • Added the ability to specify ring allocation logic for any socket type.  
         | • Improved the VMA service installation under different Linux service managers. |
| 8.7.5   | • Added support for TCP Rx timestamping.  
         | • Added support for an additional ring allocation logic: Ring logic per IP  
         | • Usage: `VMA_RING_ALLOCATION_LOGIC_RX/TX = 1`  
         | • Added support for IP_TTL socket option.  
         | • Added support for re-establishing lost connection with VMA daemon.  
         | • Added support for sendfile() and sendfile64() functions, where in_fd is a file descriptor open for reading, and out_fd is an offloadable socket.  
         | • Added support for IPoIB in upstream/inbox drivers for ConnectX-4 and above adapter cards. |
## 15.2 Bug Fixes History

The following table lists the issues that have been resolved in previous VMA versions.

<table>
<thead>
<tr>
<th>Internal Ref. Number</th>
<th>Details</th>
</tr>
</thead>
</table>
| **3604175** | **Description:** Fixed VMA hanging infinitely while closing ring with empty RQ.  
**Keywords:** ring, termination, stuck, hang up  
**Discovered in Version:** 9.8.30  
**Fixed in Version:** 9.8.40 |
| **3591039** | **Description:** Fixed RX buffer leak in case of GRO and out of order packets. Fixed TCP stream corruption in case of out of order packets.  
**Keywords:** TCP, corruption, out of order, GRO  
**Discovered in Version:** 8.4.101  
**Fixed in Version:** 9.8.40 |
| **3604175** | **Description:** Fixed VMA hanging infinitely while closing ring with empty RQ.  
**Keywords:** ring, termination, stuck, hang up  
**Discovered in Version:** 9.8.30  
**Fixed in Version:** 9.8.40 |
| **3525812** | **Description:** Fixed SocketXtreme RX buffer leak.  
**Keywords:** SocketXtreme, leak  
**Discovered in Version:** 9.8.20  
**Fixed in Version:** 9.8.31 |
| **3373882** | **Description:** Fixed a compilation error with gcc 13.0.1.  
**Keywords:** gcc compilation error  
**Discovered in Version:** 9.8.1  
**Fixed in Version:** 9.8.20 |
| **3173318** | **Description:** Fixed the issue where VMA Debian package installation for Docker container failed.  
**Keywords:** Debian, Docker, Installation  
**Discovered in Version:** 9.7.0  
**Fixed in Version:** 9.7.2 |
| **3173318** | **Description:** Fixed the issue where using send* functions with null elements in iov Tx vector causes an API error.  
**Keywords:** iov Tx vector  
**Discovered in Version:** 9.6.4  
**Fixed in Version:** 9.7.0 |
<table>
<thead>
<tr>
<th>Internal Ref. Number</th>
<th>Details</th>
</tr>
</thead>
</table>
| 3092554             | **Description:** When VMA_HANDLE_SIGINTR=0, the following issues are no longer encountered:  
1. When SIGNIT is caught by VMA, subsequent calls to socket API return EINTR error code immediately.  
2. VMA_HANDLE_SIGINTR parameter is ignored by signal() API. However, when VMA_HANDLE_SIGINTR=1, only the first issue persists.  

**Keywords:** SIGINT; EINTR; signal; sigaction  
**Discovered in Version:** 9.5.2  
**Fixed in Version:** 9.6.4 |
| 3092555             | **Description:** Fixed the issue of when attempting to perform a second connect() after the first connect() has failed, a segmentation fault took place. Now, an error is received upon second attempt instead.  

**Keywords:** connect(); blocking socket; segmentation fault  
**Discovered in Version:** 9.5.2  
**Fixed in Version:** 9.6.4 |
| 3045735             | **Description:** Fixed the issue where there was no traffic as long as SR-IOV mode was disabled.  

**Keywords:** SR-IOV; traffic  
**Discovered in Version:** 9.3.1  
**Fixed in Version:** 9.6.4 |
| 2740920             | **Description:** Added support for fortified glibc functions as __read_chk, __recv_chk, __recvfrom_chk, __poll_chk, __ppoll_chk.  

**Keywords:** socket API  
**Discovered in Version:** 9.3.0  
**Fixed in Version:** 9.4.0 |
| 1714768             | **Description:** Fixed memory leak in vma_free_packets() implementation.  

**Keywords:** Extra API  
**Discovered in Version:** 8.8.2  
**Fixed in Version:** 9.4.0 |
| 2366027             | **Description:** Fixed big-endian support for TIMESTAMP option.  

**Keywords:** TCP  
**Discovered in Version:** 9.0.2  
**Fixed in Version:** 9.3.1 |
| 2280628             | **Description:** Added TIMESTAMP option into keepalives and zero window probes TCP packets.  

**Keywords:** TCP  
**Discovered in Version:** 9.0.2  
**Fixed in Version:** 9.3.1 |
<table>
<thead>
<tr>
<th>Internal Ref. Number</th>
<th>Details</th>

</thead>
</table>
| 2246994 | **Description:** Set proper FIN/RST flags for splitted TCP segments.  
**Keywords:** TCP  
**Discovered in Version:** 9.1.1  
**Fixed in Version:** 9.3.1 |
| 2130901 | **Description:** Fixed forever loop condition during finalization after setting VMA_PROGRESS_ENGINE_WCE_MAX=0.  
**Keywords:** Hangup  
**Discovered in Version:** 9.0.2  
**Fixed in Version:** 9.3.1 |
| 1775713 | **Description:** Fixed a synchronization issue in attach/detach flow when VMA is configured to use 3tuple (software rule).  
**Keywords:** Cleanup  
**Discovered in Release:** 8.4.10  
**Fixed in Version:** 9.2.2 |
| 2233349 | **Description:** Fixed wrong detection of huge pages with different sizes.  
**Keywords:** Huge Page  
**Discovered in Version:** 9.1.1  
**Fixed in Version:** 9.2.2 |
| 2355289 | **Description:** Fixed wrong detection of Blue Flame usage capability.  
**Keywords:** Blue Flame  
**Discovered in Version:** 9.1.1  
**Fixed in Version:** 9.2.2 |
| 2132032 | **Description:** Fixed an issue where all traffic was received in one top socket when several sockets were bound to the same IP:PORT pair and used 5 different tuple rules.  
**Keywords:** UDP steering  
**Discovered in Version:** 9.0.2  
**Fixed in Version:** 9.1.1 |
| 2009931 | **Description:** Added fcntl64() support.  
**Keywords:** Socket API  
**Discovered in Version:** 8.9.5  
**Fixed in Version:** 9.1.1 |
| 2074332 | **Description:** Fixed the issue where vma_stats utility reported wrong statistics.  
**Keywords:** vma_stats  
**Discovered in Version:** 9.0.1  
**Fixed in Version:** 9.1.1 |
| 1973965 | **Description:** Replaced dropped packets statistics data with EAGAIN.  
**Keywords:** vma_stats |
<table>
