Chapter 1.
OVERVIEW

The NVIDIA® driver supports "retiring" framebuffer pages that contain bad memory cells. This is called "dynamic page retirement" and is done automatically for cells that are degrading in quality. This feature can improve the longevity of an otherwise good board and is thus an important resiliency feature on supported products, especially in HPC and enterprise environments.
Chapter 2.
IMPLEMENTATION

The marking of a page for exclusion is called "retiring", while the actual act of excluding that page from subsequent memory allocations is called "blacklisting". The NVIDIA® driver will retire a page once it has experienced a single Double Bit ECC Error (DBE), or 2 Single Bit ECC Errors (SBE) on the same address. These addresses are stored in the InfoROM. When each GPU is attached and initialized the driver will retrieve these addresses from the InfoROM, then have the framebuffer manager set these pages aside, such that they cannot be used by the driver or user applications.

Retiring of pages may only occur when ECC is enabled. However, once a page has been retired it will always be blacklisted by the driver, even if ECC is later disabled.

Ideally, the NVIDIA® driver will catch weakening cells at the 2 SBE point and retire the page, before the cell degrades to the point of a DBE and disrupts an application.

2.1. Use Case 1: DBE Detected

- The NVIDIA® driver detects a DBE and reports that a DBE occurred.
- Applications will receive a DBE event notification for graceful exit, and no further context will be created on the GPU until the DBE is mapped out.
- The NVIDIA® driver logs the DBE count and address in the InfoROM.
- The NVIDIA® driver logs, in a separate list, that the page containing the DBE is to be retired.
- Upon the next reattachment of the GPU, the page is mapped out of usage.

The DBE addresses and counts are preserved across boots.
2.2. Use Case 2: Two SBEs Detected at the Same Location

- The NVIDIA® driver detects an SBE and reports that an SBE occurred.
- The NVIDIA® driver logs the SBE count and address in the InfoROM.
- If the SBE occurs more than once in a particular address, the driver logs, in a separate list, that the page containing that address is to be retired.
- Upon the next reattachment of the GPU, the page is mapped out of usage.

Unlike the DBE case, applications continue to run uninterrupted.

The SBE addresses and counts are preserved across boots.
Pages that have been previously retired are blacklisted for all future allocations of the framebuffer, provided that the target GPU has been properly reattached and initialized. This chapter presents a procedure for ensuring that retired pages are blacklisted and all GPUs have recovered from the ECC error.

This procedure requires the termination of all clients on the target GPU. It is not possible to blacklist a new page while clients remain active.

Blacklisting: Procedure Overview:
- Verify that there are pending retired pages.
- Determine GPUs that are related and must be reattached together.
- Stop applications and verify there are none left running.
- Reinitialize the GPU, or reboot the system.
- Verify that blacklisting has occurred.
- Restart applications.

### 3.1. Verifying Retired Pages are Pending

When pages are retired but have not yet been blacklisted, the retired pages are marked as pending for that GPU. This can be seen through nvidia-smi:

```
$ nvidia-smi -i <target gpu> -q -d PAGE_RETIREMENT
...
Retired pages
  Single Bit ECC : 2
  Double Bit ECC : 0
Pending          : Yes
...
```

If pending shows "No", then all retired pages have already been blacklisted.

If pending shows "Yes", then at least one of the retired pages that are counted are not yet blacklisted. Note that the exact count of pending pages is not shown.
3.3. Stopping GPU Clients

Before the NVIDIA® driver can reattach the GPUs, clients that are using those GPUs must first be stopped and the GPU must be unused.

All applications that are using the GPUs should first be stopped. Use nvidia-smi to list processes that are actively using the GPUs. In the example below, a tensorflow python program is using both GPUs 0 and 1. Both will need to be stopped.

```
$ nvidia-smi
+---------------------------------------------------------------------+
| Processes:                                               GPU Memory |
| GPU       PID   Type   Process name                     Usage      |
|=====================================================================|
|    0      8962      C   python                             15465MiB |
|    1      8963      C   python                             15467MiB |
+---------------------------------------------------------------------+
```

Once all applications are stopped, nvidia-smi should show no processes found:

```
$ nvidia-smi
+---------------------------------------------------------------------+
| Processes:                                               GPU Memory |
| GPU       PID   Type   Process name                     Usage      |
|=====================================================================|
| No running processes found                                         |
+---------------------------------------------------------------------+
```

On Linux systems, additional software infrastructure can hold the GPU open and prevent the GPU from being detached by the driver. These include the nvidia-persistenced, and version 1 of nvidia-docker. Nvidia-docker version 2 does not need to be stopped.

A list of open processes using the driver can be verified on Linux with the lsof command:

```
$ sudo lsof /dev/nvidia*
COMMAND   PID                USER   FD   TYPE  DEVICE NODE NAME
nvidia-pe 941 nvidia-persistenced    2u   CHR 195,255  453 /dev/nvidiactl
nvidia-pe 941 nvidia-persistenced    3u   CHR 195,0  454 /dev/nvidia0
nvidia-pe 941 nvidia-persistenced    4u   CHR 195,254  607 /dev/nvidia-modeset
nvidia-pe 941 nvidia-persistenced    5u   CHR 195,1  584 /dev/nvidia1
nvidia-pe 941 nvidia-persistenced    6u   CHR 195,254  607 /dev/nvidia-modeset
```

Once all clients of the GPU are stopped, lsof should return no entries:

```
$ sudo service nvidia-persistenced stop
$ sudo lsof /dev/nvidia*
$ 
```
3.4. Reattaching the GPU

Reattaching the GPU, to blacklist pending retired pages, can be done in several ways. In order of cost, from low to high:

- Re-attach the GPUs (persistence mode disabled only)
- Reset the GPUs
- Reload the kernel module (nvidia.ko)
- Reboot the machine (or VM)

Reattaching the GPU is the least invasive solution. The detachment process occurs automatically a few seconds after the last client terminates on the GPU, as long as persistence mode is not enabled. The next client that targets the GPU will trigger the driver to reattach and blacklist all marked pages.

If persistence mode is enabled the preferred solution is to reset the GPU using nvidia-smi. To reset an individual GPU:

```
$ nvidia-smi -i < target GPU> -r
```

Or to reset all GPUs together:

```
$ nvidia-smi -r
```

These operations reattach the GPU as a step in the larger process of resetting all GPU SW and HW state.

Reloading the NVIDIA® kernel module triggers reattachment of all GPUs on the machine, and thus requires the termination of all clients on all GPUs.

Finally, rebooting the machine will effectively reattach the GPUs as the driver is reloaded and reinitialized during reboot. While rebooting isn't required and is highly invasive, it might simplify the recovery action in some operating environments.

3.2. Overview

The NVIDIA® driver supports "retiring" framebuffer pages that contain bad memory cells. This is called "dynamic page retirement" and is done automatically for cells that are degrading in quality. This feature can improve the longevity of an otherwise good board and is thus an important resiliency feature on supported products, especially in HPC and enterprise environments.
3.5. Overview

The NVIDIA® driver supports "retiring" framebuffer pages that contain bad memory cells. This is called "dynamic page retirement" and is done automatically for cells that are degrading in quality. This feature can improve the longevity of an otherwise good board and is thus an important resiliency feature on supported products, especially in HPC and enterprise environments.
Dynamic page retirement is supported on the following products and environments:

- Drivers: R319 and newer
- OSes: All standard driver-supported Linux and Windows TCC platforms
- GRID: Supports dynamic page retirement in Pass-Through mode only (not for VGPU)
- GPUs:
  - K20 and newer Tesla products
  - GV100 and newer Quadro products
  - No GeForce products are currently supported
Chapter 5.
VISIBILITY

Three main mechanisms provide visibility into page retirement: XID errors in system logs, the NVML API and the nvidia-smi command line tool.

5.1. XIDs

XID errors are driver errors that are logged to the system error log. Please see the XID Whitepaper for general info on XIDs.

There are three main XIDs related to dynamic page retirement:

- XID 48: A DBE has occurred.
- XID 63: A page has successfully been retired.
- XID 64: A page has failed retirement due to an error.

In the system log these XIDs show up in the following forms:

- XID 48: "XID 48 An uncorrectable double bit error (DBE) has been detected on GPU (<id>)"
- XID 63: "XID 63 Dynamic Page Retirement: New retired page, reload the driver to activate. (<address>)"
- XID 64: "XID 64 Dynamic Page Retirement: Fatal error, unable to retire page (<address>)"

5.2. NVML

The NVIDIA® Management Library (NVML) is a public C-based library for GPU monitoring and management. It includes APIs that report the status and count of retired pages. Please see the NVML API docs for general info on the library.

The set of currently retired pages, and their addresses, can be retrieved using:

```
nvmlReturn_t nvmlDeviceGetRetiredPages (nvmlDevice_t device,
   nvmlPageRetirementCause_t cause, unsigned int* pageCount, unsigned long long* addresses)
```
Driver versions 410.72 or later provide a newer API that also returns page retirement timestamp:

```c
nvmlReturn_t nvmlDeviceGetRetiredPages_v2 (nvmlDevice_t device, 
nvmlPageRetirementCause_t cause, unsigned int* pageCount, unsigned long long* 
addresses, unsigned long long* timestamps)
```

For both APIs, the `nvmlPageRetirementCause_t` passed is one of:

- `NVML_PAGE_RETIREMENT_CAUSE_MULTIPLE_SINGLE_BIT_ECC_ERRORS`
- `NVML_PAGE_RETIREMENT_CAUSE_DOUBLE_BIT_ECC_ERROR`

The current state of the driver (whether any pages are pending retirement) can be retrieved using:

```c
nvmlReturn_t nvmlDeviceGetRetiredPagesPendingStatus (nvmlDevice_t device, 
nvmlEnableState_t* isPending)
```

### 5.3. Nvidia-smi

Nvidia-smi is a public command line interface for GPU monitoring and management. It implements most of the NVML APIs and supports reporting the status and count of retired pages. Please see the Nvidia-smi man page for general info on the tool.

To view the number of retired pages and the page retirement state of the driver in human readable form:

```bash
$ nvidia-smi -i <target gpu> -q -d PAGE_RETIREMENT

... Retired pages
  Single Bit ECC : 2
  Double Bit ECC : 0
  Pending        : No
...
```

If pages have been retired the affected addresses can be viewed through nvidia-smi’s scriptable outputs, either XML:

```xml
$ nvidia-smi -i <target gpu> -q -x

...<retired_pages>
  <multiple_single_bit_retirement>
    <retired_count>2</retired_count>
    <retired_pagelist>
      <retired_page>
        <retired_page_address>0xABC123</retired_page_address>
        <retired_page_timestamp>Thu Oct  4 14:49:27 2018</retired_page_timestamp>
      </retired_page>
      <retired_page>
        <retired_page_address>0xDEF456</retired_page_address>
        <retired_page_timestamp>Thu Jun 15 14:49:27 2017</retired_page_timestamp>
      </retired_page>
    </retired_pagelist>
  </multiple_single_bit_retirement>
</retired_pages>
```

or CSV:

```
$ nvidia-smi -i <target gpu> --query-retired-pages=gpu_uuid,retired_pages.address,retired_pages.cause --format=csv
...  
gpu_uuid, retired_pages.address, retired_pages.cause
GPU-d73c8888-9482-7d65-c95c-4b58c7d9eb4c, 0x0000000BCD234, Double Bit ECC
GPU-d73c8888-9482-7d65-c95c-4b58c7d9eb4c, 0x0000000AEF567, Double Bit ECC
GPU-d73c8888-9482-7d65-c95c-4b58c7d9eb4c, 0x0000000123ABC, Single Bit ECC
...```

There exists a race condition between logging errors to the InfoROM and ending a CUDA™ job while in persistence mode. This race condition is most often hit when shutting down in response to a DBE. The effect of this condition is that a page may fail to retire in certain corner cases.

Exiting persistence mode before rebooting the system will forcibly flush any pending writes to the InfoROM. If XID 48 is seen and XID 63 is not seen, it is recommended to exit persistence mode via the command:

```
% nvidia-smi -i <target GPU> -pm 0
```

At this point, the XID 63 should be seen and the NVML query can be used to verify the page was written to the InfoROM.

There are no current plans to fix the race condition in persistence mode, as persistence mode is replaced by the persistence daemon. The persistence daemon is not susceptible to this race condition.
Chapter 7. FAQ

7.1. Memory Impact

Is available memory reduced by retired pages?
Each retired page decreases the total memory available to applications. However, the total maximum size of memory retired in this way is only on the order of 4 MiB. This is insignificant relative to other factors, such as natural fluctuations in memory allocated internally by the NVIDIA® driver during normal operation.

What is the size of each retired page?
64KiB

How many pages can be retired?
A combined total of 60 pages can be mapped out, or retired. This can be any combination of DBE and SBE pages.

How many addresses can be stored in the InfoROM?
The InfoROM can store at least up to 192 different addresses. Different GPU models and inforom formats may extend this beyond 192 addresses.

7.2. Configuration

Is ECC enabled on my GPU?
nvidia-smi can be used to show if the GPU currently has ECC enabled, and what mode is pending to be activated following a reboot.

```bash
$ nvidia-smi -q
...  
  Ecc Mode
```
Can page retirement be disabled?

No, page retirement is an important reliability feature and cannot be disabled for either SBEs or DBEs. Any pages already marked as retired will continue to be excluded in all future allocations. Note though that if ECC is disabled no new memory errors will be detected and thus no new pages will be blacklisted for future retirement.

ECC can be disabled through nvidia-smi:

```
$ nvidia-smi -e 0
Disabled ECC support for GPU 00000000:06:00.0.
All done.
Reboot required.
```

Or re-enabled, similarly:

```
sudo nvidia-smi -e 1
Enabled ECC support for GPU 00000000:06:00.0.
All done.
Reboot required.
```

Is the SBE recurrence threshold for triggering retirement be configurable?

No

7.3. App Behavior

Is application behavior affected?

No, applications behave the same. Since pages are retired only after the driver has been restarted the act of retiring a page occurs outside the lifetime of any GPU process or application. An application running on a GPU with pages scheduled for retirement (blacklisted) will continue to see those pages in its memory space, though any page retired due to a double bit error (DBE) will necessarily cause an application to terminate. This is true even without page retirement.

7.4. App Performance

Is application performance affected?

No, application performance is unaffected by either the retirement of pages or their subsequent blacklisting. Retirement is the only act taken during application execution, while the actual blacklisting event happens only after the application has terminated. As noted in the first FAQ question above, the memory impact of retired pages is also negligible.
Is memory fragmentation due to page retirement expected to impact app performance?

Fragmentation is not expected to affect performance.

7.5. Driver Behavior

Must multiple SBEs be located at the same address to trigger retirement?
Yes, multiple SBE's must be located at the exact same location (address). Multiple SBEs at different locations within the same page will not trigger page retirement.

Are "stuck" bits rewritten by the driver, or corrected on each read?
On Kepler-class GPUs and later, the driver rewrites the data to avoid stuck bits.

Are all SBE and DBE addresses tracked indefinitely?
SBE and DBE addresses are tracked indefinitely, up to the maximum number of addresses that can be stored (See Memory Impact). Additional addresses beyond the maximum are dropped.
